To Shanghai or Yokohama & back	" 6 "	510

Passengers change Steamers at Colombo.

The Company's Steamers to and from Yokohama proceed through
the Inland Sea, calling at Nagasaki and Higo.

A Handbook will be sent on applying at 19, Strand Road.

H. W. ULOTH, Supercargo.

STAR LINE OF STEAMERS

CALCUTTA TO LONDON.

CALLING at Colombo.—These fast Steamers will be despatched
punctually on the undermentioned dates:—

NAME.	TONS.	COMMANDER.	TO LEAVE CALCUTTA.
Vega	3063	J. L. Wadley	20th January 1885
Vesta	3054	E. S. Rawlings	5th February "
Mira	2606	T. Lepoutier	12th March "
Capella	3359	W. Lee	9th April "

* Will not carry passengers.

The above Steamers take Saloon Passengers only, have
spacious accommodation, are fitted with every comfort (Ice
House, Freshwater, &c.), and each carries a Surgeon and Stewardess.
The homeward passages average about 39 days, including all

FRAGRANT FLORILINE.

FOR THE TEETH AND BREATH.—A few drops of the liquid FLORILINE sprinkled on a wet tooth brush produces a pleasant lather, which thoroughly cleanses the teeth from all parasites or impurities, hardens the gums, prevents tartar, stops decay, gives to the teeth a peculiar pearly whiteness, and a delightful fragrance to the breath. It removes all unpleasant odour arising from decayed teeth or tobacco smoke. "Fits Family or Traveller," being composed in part of Honey and sweet herbs, is delicious to the taste, and the greatest toilet discovery of the age. Price, 2s. 6d., of all Chemists and Perfumers throughout the world. Sold wholesale by The Anglo American Drug Co., Limited, 33, Farringdon-road, London.

Advice to Mothers.

ARE you broken in your rest by a sick child suffering with the pain of cutting teeth? Go at once to a Chemist and get a bottle of Mrs. Winslow's Soothing Syrup. It will relieve the poor sufferer immediately. It is perfectly harmless and pleasant to the taste, it produces natural, quiet sleep, by relieving the child from pain, and the little cherub awakes "as bright as a button." It soothes the child, it softens the gums, allays all pain, relieves wind, regulates the bowels, and is the best known remedy for dysentery and diarrhoea, whether arising from teething or other causes. Mrs. Winslow's Soothing Syrup is sold by Medicine Dealers everywhere at 1s. 1d. per bottle. Wholesale by The Anglo-American Drug Company, Limited, 33, Farringdon-road, London.

Valuable discovery for the Hair.

IF your hair is turning grey or white, or falling off, use THE MEXICAN HAIR RESTORER, for it will prevent its falling out every case Grey or White Hair to its original colour, without having the disagreeable smell of most "Restorers." It cures the hair charmingly beautiful as well as promoting the growth of the hair on bald spots, where the glands are not decayed. Ask your Chemist for "THE MEXICAN HAIR RESTORER," sold by Chemists and Perfumers everywhere at 3s. 6d. per bottle. Sold wholesale by The Anglo-American Drug Company, Limited, 33, Farringdon-road, London.

GOODALL'S Household Specialities.**YORKSHIRE RELISH**

The Most Delicious Sauce in the World.

YORKSHIRE RELISH

Awarded Eight Prize Medals.

YORKSHIRE RELISH

5,000,000 Bottles Sold Annually.

YORKSHIRE RELISH

Enriches Hot Joints, Soups, Stews, &c.

YORKSHIRE RELISH

Delicious to Chops, Steaks, Fish, Poultry, &c.

YORKSHIRE RELISH

Blends Admirably with all Gravies.

YORKSHIRE RELISH

Agrees with the Most Delicate Persons.

YORKSHIRE RELISH

Makes Cold Meat a Luxury.

YORKSHIRE RELISH

Possesses a Pleasing Piquancy.

YORKSHIRE RELISH

Every Dish is Improved by its Addition.

YORKSHIRE RELISH

Suitable to the Invalid's cup of Broth.

YORKSHIRE RELISH

Should be on every Sideboard.

YORKSHIRE RELISH

Epicures pronounce it the Best Sauce.

YORKSHIRE RELISH

No better Sauce can be Made.

YORKSHIRE RELISH

A Household Word.

YORKSHIRE RELISH

Known all over the World.

Warranted pure and free from any injurious ingredient.

This Clean and Excellent Sauce makes the plainest viands palatable, and the daintiest dishes most delicious.

The most cultivated culinary connoisseurs have awarded the palm to the YORKSHIRE RELISH, on the ground that neither its strength nor its purity is overpowering, and that its invigorating zest by no means impairs the natural flavour of the dishes to which it is added.

Employed either "au naturel" as a fillip to chops, steaks, game, or cold meats, or used in combination by a skilful cook in concocting soups, stews, ragouts, curries, or gravies for fish and made dishes.

Sold in bottles, 6d., 1s., and 2s. each.

Prepared by GOODALL, BACKHOUSE & CO., Leeds, England.

Verdala Barracks, Malta, 21st Feb., 1875.

SIR,—Having been for the last four years Captain President of the 101st Fushers, I have signed orders for at least 5,000 bottles of your Yorkshire Relish, and can bear testimony to its being the best and choicest sauce extant.—Yours truly, W. SWINTEN JEVIS, Capt. 101st Fushers, P.C.C.

To Goodall, Backhouse & Co., Leeds.

INDIAN AGRICULTURIST

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA :—SATURDAY, JANUARY 3, 1885.

[No. 1.]

Crop and Weather Report.

[FOR THE WEEK ENDING THE 24TH DECEMBER, 1884.]

General Remarks.—Rain has fallen in places in the Bombay Presidency, in Mysore, and Coorg, in the Berars, and in the Central Provinces and in the Central India and Rajpootana States. In Madras there has been heavy rain in the southern districts, especially in Chingleput, and considerable damage has been caused to crops and houses.

Harvesting continues in Madras. More rain is wanted in Bellary and Kurnool, where the crops are withering. In Mysore prospects are fair; a good rice crop is being cut in Coorg; coffee-picking is progressing, but the crop deficient; a heavy fall in the price of cardamoms has been disastrous to the ryots.

Agricultural prospects continue favourable throughout the Central India and Rajpootana States. In Hyderabad the rice harvest and ploughing for the *rabi* are still in progress; cotton is being picked in the Berars, and the standing crops are in good condition. More rain is wanted in parts of some districts in the Bombay and Madras Presidencies, where the crops are withering; elsewhere the condition of the crops is generally good.

In the Punjab the *rabi* sowings have been completed and prospects are good. In the North-Western Provinces and Outh, the *rabi* crops are flourishing and prospects are very favourable.

In the Central Provinces the rain of the past week has been beneficial to the crops, and prospects have improved. In Bengal the *aman* paddy harvest will be below the average; the prospects of the *rabi* are promising. The reaping of the *sali* crop continues in Assam and prospects are good. The rice harvest continues in Burmah and a good out-turn is expected throughout the Province.

The public health is generally good, though in Coimbatore the mortality from cholera continues high.

Prices are almost stationary with local fluctuations.

Madras.—Some rain in Anantapore; prospects in Bellary not improved; considerable damage to crops and houses in southern districts, especially Chingleput, from heavy rain and floods.

Bombay.—Rain in parts of several districts, more wanted in parts of Sholapore, Dharwar, Kaladgi, and Belgaum, where crops are withering, and scarcity of fodder and drinking water prevails; standing crops slightly injured by rain in parts of Thana, Khandesh, Surat, and Ahmednagar; cholera and cattle-disease in parts of six districts, small-pox in parts of ten, and fever in parts of 15 districts.

Bengal.—There has been no rain in any of the districts of the province, except in Dinagepore, where the fall was '05; harvesting of *aman* paddy still continues, the general out-turn will be below the average; *rabi* crops are coming on well; the price of rice has fallen in some districts owing to supply of new rice which is coming into the market; sporadic cases of cholera are reported in a considerable number of districts in Bengal proper, otherwise general health good.

N.-W. Provinces and Outh.—Weather cold and reasonable; crops flourishing and prospects good; poppy has germinated well.

Punjab.—No rain, health generally good; fever decreasing in the Hissar district; *rabi* sowings completed, prospects good.

Central Provinces.—Weather cloudy; recent rain has been beneficial; health generally good, prices steady.

British Burmah.—Some cholera here and there, otherwise public health good; health of cattle also good; harvesting progressing; prospects of good out-turn in all districts.

Assam.—Weather reasonable; mornings and nights cool; harvest of *sali* crop continues; public health generally good.

Mysore and Coorg.—Prospects reported fair, and health good.

Berar and Hyderabad.—Weather cloudy; cotton-picking continues; crops in good condition; general health good.

Central India States.—Weather cloudy; health good; agricultural prospects excellent.

Rajpootana.—Weather cold and cloudy; health good; crop prospects favourable.

Letters to the Editor.

THE NEW SIROCCO TEA DRYER.

TO THE EDITOR OF THE STATESMAN.

SIR,—I used some years ago to write now and then in your paper on tea matters. Possibly now, an occasional letter would be acceptable. Tea machinery has made great strides since those days. There are now many machines by different inventors for each process. The difficulty is, even for experts, to say which is the best among the many rollers, dryers, sifters, equalisers, and what not. I am not here going to pronounce an opinion. It may be, as many say here of tricycles (a subject to which I have lately given attention) there is no best, for each, perhaps, excels in some way. One opinion though I must give as regards tea machinery, and I feel sure it is a sound one. No "leaf-witherer" has yet been invented. Some inventors of dryers advocate their machines as fit to wither leaf. In practice all planters know it is not so. No machine fit to fire tea will ever wither leaf well. The necessities for the two machines are quite different. The leaf-witherer has yet to be invented.

But it is not tea machinery in general I wish now to discuss. I have lately seen a new tea dryer, which has, I think, a great future before it, and a few words about it may interest some of your readers. Though I call it a "New Dryer," it has an old name, the "Sirocco," and hails also from Belfast. But it in no way resembles the old machine. Still we must not quarrel with Mr. Davidson for the name he gives his new child.

I never liked the siroccos (see my Tea Book*) I thought (and I was right) they had done good work in their day, but that improvements in other dryers had left them behind. When therefore Mr. Davidson asked me to come and see his new type of machine, I went, for I like to see everything connected with tea; but I did not go thinking I should be much edified. I was much surprised. I found a virtually new machine which avoids all the faults of the old Sirocco; they were—1, result in tea, far too little; 2, burnt tea no rarity; 3, tea dried partly by the heat given out from hot iron; 4, the iron of the machine burnt; 5, much of the heat escaped up the chimney, and was given out uselessly from the faces of the machine.

As I say, all these drawbacks are now done away with, and I feel sure the new type of Sirocco will be a favorite in Indian tea gardens. I should hold the same opinion had I alone seen it, for I spent many hours over it, and have studied tea machinery too many years to be easily misled. Still, I am glad to find my opinion corroborated by many who are well au fait of the necessities for dryers. During the one month it has been exhibited in Gracechurch-street, Mr. Davidson has sold between 60 and 70. It would take a couple of columns in your paper to describe the new Sirocco, and I cannot ask you for the space. I only wish here to call attention to it, for those of your readers who want to know more, will find two long articles of mine written last week in the *Tea Gazette*, in which all and everything about it is stated, and also why I think it is destined to prove a great benefit to the tea industry in India.

With 9 and 10 annas per lb., and sometimes less as an usual average for tea, the days are gone by for expensive machinery. Let it be ever so good, it won't pay to buy it. Excepting Mr. Davidson and one other, I do not think the inventors and vendors of tea dryers realise this stern fact. I do not see in some cases that those machines are any cheaper than formerly. But while Mr. Davidson certainly does sell cheaper than others, it may

* Tea Cultivation and Manufacture. By Lieutenant-Colonel Edward Money (4th edition). Thacker, Spink and Co., Calcutta.

be partly owing to the fact that he can do so. Other inventors have to provide for the manufacturer's profits; not so Mr. Davidson, for he is his own manufacturer. Anyhow, there is no doubt his prices are low. The new Sirocco No. 3, turning out 10 maunds of Tea per day, is £90 complete, while the parts required to alter the old class of Siroccos, and make them of the new type, is £23 only. One great advantage achieved by Mr. Davidson is the fact that the many old Siroccos now throughout India can, at the above nominal cost, be altered into the new type.

As the said new type has in it all the requisites to produce desirable and perfectly fired teas, I in no way doubt that it will do so. But as many of the machines will be very shortly in India, and will there be tested, let those who may doubt, wait and see for themselves.

I could say a good deal on tea machinery in general, which I think would interest such of your readers as "are in tea" (how many there are), but I must not tire you with this first letter.

EDWARD MONEY.

Editorial Notes.

WE understand that two scholarships of Rs. 40 a month, tenable for three years, at the Saidapet Agricultural College, are to be offered to lads in British Burmah. This is a step in the right direction, for young men who have had the advantage of a scientific training in agriculture would be most useful there, where it is so very difficult to get the farmer to leave his accustomed groove. On their return they might be expected to turn their attention to some of the many products which could be as easily grown as paddy, and which would yield a still better return.

THE report on the Bombay Stationery Department, for the year 1883-84 shows that—the Government orders to the contrary notwithstanding—a less amount of stores of Indian manufacture was issued than in the previous year. The actual difference in value amounted to Rs. 1,356. But the report contains a statement, showing that, even if these articles of Indian manufacture had been procured from England, there would have been a loss to the Government of Rs. 4,748, a fact which clearly proves the desirability of increasing the consumption of Indian manufactured articles as much as possible.

SOME ingenious Borahs of Neriad and Kapadwanj are in trouble, and are likely to do penance for their ingenuity. They invented a novel kind of *ghee*, being a combination of *kabri*, or *kosamba* seed, and buffalo fat, so well assimilated as to present all the appearance and odour of *ghee*. As there was an appreciable difference in the price, in the way of cheapness, the ingenious inventors were doing a roaring business in it, until a short time ago the trick was discovered, much to the amazement and horror of a good many orthodox Hindoos who had thus partaken of buffalo fat. The matter is before the police authorities.

TRAVELLERS continue to leave Aden for the Galla country, where they say there is much wealth. Gold, it is asserted, is not estimated at its real value, and its weight in silver is readily received in exchange. Traders with the Somali coast also state this to be a fact; but the Somalis on the coast are less ignorant of its value; silver is their coinage, and silver ornaments only are worn. The last traveller to leave Aden was a very young Italian of noble family. He will enter the Galla country via Massowah, as he is doubtful as to the safety of the Assah or Obok route. He is rather nervous as to the success of his journey, notwithstanding that he has already had much experience as a traveller in the Sudan.

A WRITER in *St. James's Gazette* calls attention to the havoc which has been going on for so many years in the forests of every quarter of the globe; but no apology can be necessary for returning to a subject which must speedily compel the hearing now too generally denied. He says:—"The chief seat of the destruction is at present in the United States, where

it has been long progressing at a rate which has often excited the fears even of the persons engaged in it." But some facts and figures just published in an American journal, are of a kind which, combined with the manner of their statement, should surely have power to do more than raise an incredulous eyebrow. It is said that "the lumber industry will, in all probability, in the course of ten years or so, be transferred from the northern lake region to the south." Few persons will realize all that this matter-of-fact announcement implies; but it is, in reality, a comprehensive admission of the truth of the charges made against the lumbermen's practices. It means this: that the twenty years, which a short time since was the period allowed by the Lumbermen's Exchange in Chicago "for the exhaustion of the pine forests of their district," formed an unnecessarily liberal estimate. The statement means, moreover, that when the 146,000 hands now engaged in the business, have felled the last tree in the northern territory, they will be by no means content with the contemplation of their work. "The magnificent pineries of Michigan and other States in the lake region, are fast disappearing before the axe; but the whole south is a forest region, and when the northern lumber supply fails, the great saw-mills will be removed to the southern forests, and these will become the new centres of the industry."

THERE is a savour almost of brutality about this bare summary of the situation. No touch of regret softens either record or forecast; and that the latter will in due course be justified, there seems unhappily little reason to doubt. During seven months of the year 200,000 feet of lumber are daily sawn into planks in one mill in Ottawa, and there are over 25,000 such establishments at work in the country. It is obvious that not even the majestic areas of the American forests can long stand before such a terribly destructive force, exercised without judgment, and succeeded by no system that makes practical restitution to the soil. Of the results of this wholesale denudation there are already abundant signs. In the States chiefly affected, the volume of many of the tributary streams is lessened, droughts are frequent, and the productive qualities of the neighbouring farms seriously impaired. It was observed by Humboldt, that in the tropical regions an immense variety of trees live separately or "unsocially;" and it is clear that, owing to the immediate benefit reaped from them, trees thus situated are more jealously conserved than their woodland brethren. It is the province of forests beneficently to modify the climate of the adjacent plains, in the cultivated enclosures of which their loss is the most appreciable. Of the succour thus afforded there is, however, little general recognition—unless, indeed, by the forestry officers appointed by the Governments who systematically evade their representations. Many portions of Australia and New Zealand are also, in their turn, suffering from the multitude of "clearings" made by the early settlers, whose crude efforts may to some extent be condoned by the exigencies of their position. Even now, however, many colonial areas of cultivation—of which rather boastful accounts are given—are annually extended by their unconsidered destruction of the forests on which much of their ultimate fruitfulness must depend.

THE "progress" of Florida has of late years been remarkable. This State contained in 1860 only 6,586 farms, a number which had risen to 23,438 in 1880. We are told that this indicates a large influx of farmers from other States; but it also "indicates" a wide levelling of the forests of oak and cedar, pine and hickory, for which Florida was once famous. The pampas of South America are also gradually falling under cultivation, and are here and there covered with crops of wheat and maize. Their permanent productiveness, however, will be greatly assisted by the maintenance of the bordering forests; a fact of which the Argentine Government appears to be quite exceptionally conscious. In Canada, on the contrary, the long indifference of the authorities to an average annual production of no less than 2,600,000,000 feet of lumber (broad measure), has been at last compelled to give place to anxiety; and the Dominion Government is now reserving large "blocks" of forest at the base of the Rocky

Mountains, lest the injury to the climate should become irreparable. From an interesting paper contributed by Sir George Birdwood, to the catalogue of the Indian Section of the Forestry Exhibition, it is apparent that, east and west, there has been a singular community of official apathy upon this subject. Of Afghanistan the writer declares that "a once fertile and wealthy country has thus been converted into an inhospitable desert." The Forest Department of India has happily been able to arrest, and in some degree repair, the ravages which up to some forty years ago had been going on for centuries in the forests of India and Burmah. The whole of Central Asia has more or less suffered from similar causes.

.

THE first report on the prospects of the wheat crop in the Central Provinces is as follows:—"Preliminary wheat forecasts as yet received from only six districts; but from them and from personal enquiry, it appears that, owing to continuousness of rainfall and its early cessation, there is a very general decrease of from 5 to 10 per cent in area; maximum decrease in Wardha, which is reported to be 32 per cent. The area has further been decreased in Chutisgarh by extensive mortality of cattle; sowings have germinated strongly when effected early, but late sowings have come up unequally. Condition of crop is on the whole up to the average for this period, but rain is much needed, and if it occurs, an average out-turn may be expected."

.

THE first report on the prospects of the wheat crop in the Bombay Presidency is as follows:—"Reports not received from Dharwar, Khandesh, Nasik, Satara, Panchmahals, and Sindh. Ahmedabad,—Wheat area 265,624 acres, or 40 per cent more than last year owing to favourable late rains; seedlings germinating; young crops thriving. Ahmednugger,—244,671 acres, or 15 per cent less; in some parts area greater than in last year, in other parts decrease due to want of rain and smaller area devoted to wheat this year. Seeds have germinated in parts; crop good, in others they have withered on account of off rain and cloudy weather in November. Kaladgi,—123,662 acres. The crop will be, it is feared, a total failure for want of sufficient rain. Broach,—11,922 acres, or 55 per cent more owing to injured cotton land having been re-sown with wheat; crop promising. Belgaum,—91,298 acres; sowings have not germinated in all places: crops in places good, in others withering. Poona,—80,000 acres, or 2 per cent less. Sowings germinated; crops thriving. Sholapore,—41,730 acres, or 20 per cent less owing to deficient rain-fall. Kaira,—29,781 acres, or 24 per cent more owing to late favourable rain-fall. Sowings germinated; crops progressing. Generally speaking, the area and condition of the wheat crop are satisfactory in the Guzerat districts; the crop area and condition in the Deccan and Kanarese districts are unsatisfactory from want of rain."

.

A FRENCH Journal calls attention to M. Raoul Pictet, of Geneva, having introduced the use of sulphurous acid in combination with artificial cold, in the manufacture of wood pulp. Under the usual sulphite process the chopped wood is boiled for several days in closed vessels, with a solution of sulphite of lime or magnesia, ere the cellulose is separated from its surrounding constituents. But the cellulose resists a temperature lower than 180° Cent; accordingly the above boiling solutions are kept at a temperature of 150° to 160° Cent. and the resultant pulp is charred and blackened by the innumerable particles of carbon caused by the gums, resins, and other incasing materials of the cellulose being disintegrated whilst it is being boiled,—much subsequent washing and bleaching is consequently required to make the pulp a marketable material. M. Pictet takes advantage of the fact that these alien matters may be disengaged from the cellulose at a temperature of only 80° Centigrade, and effects this at once by a concentrated solution of sulphurous acid and water, at the above temperature, along with a pressure of five atmospheres. The pulp is a beautiful white material; while the gums, resins, and other material may be subsequently recovered from the lye-wash, and utilized in the arts.

LEITNER publishes the following formula for making a liquid paste or glue, from starch and acid:—Place five pounds of potato starch in six pounds of water, and add one quarter pound of pure nitric acid. Keep it in a warm place, stirring frequently for forty-eight hours. Then boil the mixture until it forms a thick and translucent substance. Dilute with water, if necessary, and filter through a thick cloth. At the same time another paste is made from sugar and gum arabic. Dissolve five pounds gum arabic and one pound of sugar in five pounds of water, and add one ounce of nitric acid and heat to boiling. Then mix the above with the starch paste. The resultant paste is liquid, does not mould, and dries on paper with a gloss. It is useful for labels, wrappers, and fine book-binder's use. Dry pocket glue is made from twelve parts of glue and five parts of sugar. The glue is boiled until entirely dissolved, the sugar dissolved in the hot glue, and the mass evaporated until it hardens on cooling. The hard substance dissolves rapidly in lukewarm water, and is an excellent glue for use on paper.

.

A CONTEMPORARY lately brought to the notice of the public that a paper mill has been established in Shanghai. We are now told that the investment promises to be a success. All requisites are to be obtained without any difficulty, a plentiful supply of water, an abundance of raw material to work with, cheap manual labour, cheap motive power, and a capital market to dispose of the manufactured article. It is now close upon ten years that the enterprise was introduced into Japan by a Mr. Doyle, and since then a dozen mills are in full working order there. Those which have been properly constructed, and placed under efficient and skilled management, have been exceptionally successful; the mill at Osaka cleared itself in three years; while the one at Oji paid a dividend last year of 17 per cent on stock amounting to 565,000 dollars. The other mills were not quite so successful; but no failure has been recorded, and what is more, the entire enterprise of paper manufacture in Japan is now in the hands of the natives of the country, who have so far advanced in the art as to think themselves justified in being independent of foreign supervision. An interesting feature in connection with the paper trade of Japan is, that while nine or ten mills have been working successfully, the importations of foreign-made paper have considerably increased—more than doubled—during the last few years.

.

THE following paragraphs are taken from a highly interesting paper on sugar bounties, in the *Fortnightly Review* for November 1884, by George Baden-Powell, C.M.G. There must be backbone in a grievance which commands not only space for days and weeks in the columns of the *Times*, but also notice and attention in every leading journal. In the face, however, of papers presented to Parliament, leaders in all newspapers, and voluminous correspondence, official and unofficial, public and private, there still remain three or four points which I put forward in this article, as they contain the gist of the whole grievance, as well as the only practicable remedy. I state them in summary at the end of the article. Why they have not as yet obtained due prominence in the controversy is because side issues have monopolised all attention. Everyone who has looked into the question acknowledges there is evil somewhat. From Secretaries of State, downwards, there is a general and decided, although strongly undefined, conviction, that the bounty system is on the whole an evil system, and should be put an end to. Popular definitions of the evil coincide in declaring that bounties have brought about such an artificial lowering of the prices of raw and refined sugar, that sugar producers and refiners can no longer produce or refine except at a dead loss, and the public refuse to pay heed to any remedy except that of a countervailing duty. I venture to say that this generally-accepted definition of the evil is both inadequate and inaccurate, and that the popular remedy declared by those in authority, to be impracticable and ineffectual, is by no means the only remedy.

.

It would be well to recall, in outline, the arguments that have been advanced on either side. The West India

have put their case very strongly—pointing out the great value of the West India sugar industry; its paramount importance to the prosperity, or indeed the very life of those colonies; the ruin and starvation which would follow on its destruction; and the responsibility which rests upon England, as the paramount power, to act effectually in defence of West Indian interests, or to bear the consequences and costs of inaction. In addition to this, they point out that the production of beet-sugar has, roughly speaking, trebled in amount, while that of cane-sugar has done little more than hold its own; all of which they attribute directly to bounties; and, having thus made their definition of the evil, they proceed to advocate, as a remedy, a countervailing duty. English refiners tell the public distinctly that bounties on refined sugar lessen by so much the price in the English market, and so not only rob them of legitimate profits, but force them to sell at a loss or accept absolute ruin. They also point out that so long as the bounty system is possible, there is absolute and hurtful uncertainty in the whole trade. Nor do they scruple to warn other trades and industries that if the system be allowed, and not stigmatized as contrary to the true spirit of international comity and intercourse, bounties may at any moment upset any other trade or industry. When the right time comes the Chancellor of the Exchequer will discover a very material falling off in the returns from the Income Tax, and he will find this to be largely due to the fact that all connected with sugar—planters, manufacturers of machinery, refiners, merchants, and brokers—are now making no nett incomes. The amount so lost to the revenue will have to be made good by the nation in the capacity of tax-payers, and this loss of income will be found to be no adequate set-off against the advantages it obtains from bounties, in its capacity of consumer.

.

AGAINST these trade grievances the Board of Trade puts forward elaborate rejoinders. These show that many of the statements made in support of the grievances are founded on a misapprehension of facts; in some cases this modifies rather than destroys the grounds of their grievances. West Indian planters are asked to remember that quite as serious anticipations of absolute ruin have before now been falsified by the event. This is, of course, an appeal to the future, but West Indians have this argument on their side, that there is a minimum cost at which sugar can be grown, and that prices never before falling below 17s. have in this crisis fallen to 11s., and that there is thus a new danger of that minimum being passed. These rejoinders also give cold comfort in pointing out that other trades have survived crises even of greater severity; and they enumerate the advantages these low prices have been to many manufacturing industries, as well as to the consumer generally. The Board of Trade comes to the general conclusion that the alleged fall in prices would mean, that the people of the United Kingdom pay annually £5,000,000 less for their sugar; but it is also pointed out that the total amount of bounties obtained cannot exceed £2,000,000. The Board of Trade now acknowledges bounties do evil on the whole, and confesses it "would wish to see an end put to them," but that "it would not pay to get rid of them at any price," particularly if that price included the adoption by England of retrograde measures savouring of protection; and this leads them to their main argument and conclusion—that they cannot recommend Government to take any action, seeing that the remedy proposed—namely, the imposition of a countervailing duty—is not only contrary to true free-trade principles, but for a variety of reasons, impossible of application.

.

SUCH are the chief arguments on either side, but they do not go to the bottom of things. There is a great and grave discrepancy, for instance, between the £5,000,000 England is supposed to save in its annual expenditure on sugar, and the £2,000,000 of that amount which is contributed by the foreign tax-payers. How is this £3,000,000 to be accounted for? Is it paid out of English profits? There has been a great and general fall in the price of sugar, far and away above any fall attributable to bounties. The primary question is, what caused this fall?

We are too apt in regard to food, to measure consumption, for statistical purposes, by records of production. We do not do this in iron or piece-goods. But directly we deal with wheat or sugar we take an estimate of home productions not exported, and add to this the imports, divide by heads of population, and write homilies on "the movements of consumption." The general public is thus misled altogether in cases of over-production; and no notice is paid to the fact that oftentimes there is more food in stock than the day-to-day demand needs. This is undoubtedly the state of the case in regard to sugar just now. There is production altogether in excess of demand. All over the world, in recent years, a very remarkable impetus has been given to the production of sugar. Cane-growing, at one time almost a monopoly of the West Indies, has developed largely in North and South America, in Natal, in Mauritius, in Australia, in Fiji, and, above all, in India, Java, and the East generally—not even forgetting hapless Egypt. It is, of course, to be noticed that concurrently with this great development of production, there have grown up in North America and in Australia, great new communities of sugar-eating Anglo-Saxons, and that these new markets call for new areas of supply. But even these numbers by no means account for the enormous increase in out-put. For instance, if we take England, we find a very remarkable increase in the local consumption of sugar, altogether out of proportion to mere increase of population. The sugar used per head of population has increased from 15lbs. in 1840, to 64lbs. in 1880. It is perfectly obvious that people do not eat and drink now more than four times as much sugar as they did in 1840, or twice as much as they did twenty years ago. These figures show that the quantity "used" must be accounted for, not by increased consumption, pure and simple, but by the fact that we use more sugar in various manufactures—such as distilling and the making of wine, jam, beer, soap, aerated waters, and even varnish, boot-blackening, and druggets. In some cases more sugar is used because of increase in out-put of the article manufactured; but in others sugar merely supplants other raw materials. One great cause of this increased use of sugar is its low price, and its low price is due to the extension of production, regardless of all demands of food consumption. But it must be asked, why has production increased so rapidly and so determinedly, in the face of falling prices and increasing profits? It must suffice here to state that there has been a natural development of cane-growing, to supply the natural increase in the normal consumption of sugar as a food; but there has been a great abnormal increase in the production of sugar from beet-root, due not to any legitimate demand, but to the bounties which represent, at present prices, an advantage of 30 per cent on the beet sugar exported, and of 10 per cent on the total produced. We have proof in the fact, that in the last three years in Austria, bounties were stopped, and the out-put fell 17 per cent; in France, reduced, and it rose only 27 per cent; in Germany, maintained high, and it rose over 48 per cent.

.

ALL the world knows that no Continental Government gives bounties, but that the duties are levied on the beet or juice as it goes into the factory, on calculations of the average amount of sugar that should be extracted. The average has to be calculated on previous knowledge, and the manufacturers, applying new devices, easily exceed the old averages. On exporting this sugar they receive a drawback as if duty had been paid on all of it. It is also undoubted that much fraud is practised. For instance, a Belgian fabricant confessed, that he "pressed" his roots in the presence of the Government official, and paid on the juice then and there extracted; but he "pressed" lightly, and when the official work and record was over for the day, the roots were again pressed in private, and found still to contain a large amount of juice, on which no duty was paid, although a drawback was subsequently obtained on the sugar made out of it. Also, in many cases, a drawback is obtained on sugar made out of molasses on which no duty had been paid. Again, instances are far too common, of gross and deliberate adulteration of the finished article, earthy and vegetable matters obtaining drawbacks, as

if pure sugar. Altogether, fabricants and refiners manage to create a large margin of "sugar," on which they obtain a drawback, although it has never paid duty. It may not be out of place to explain the case by an illustration. In round figures the "fabricant" pays £6 on every 10 tons of beet that he uses, on the understanding that out of this he will make 1 ton of sugar. But by improved processes and other means he turns out $1\frac{1}{2}$ tons. If in the year he works 10,000 tons of beet he pays £6,000 in duty, and turns out 1,500 tons of sugar. If he exports this he receives from Government a drawback, the equivalent of the duty, of £6 per ton, or, in other words, £9,000. The tax-payer provides him with £3,000 per annum for every 1,500 tons of sugar. It is thus obvious that he can carry on his industry at a profit, even though his sugar costs more to produce than cane sugar, by 20s., 25s., 30s., or even 35s. per ton.

THUS this bounty system, *without any reference to prices*, has led to an enormous expansion of production, altogether unwarranted by the demands of consumption or the gains of legitimate competition. The bounties directly stimulate over-production for export, but at the same time it is necessary that they be accompanied by high excise duties, sur-taxes, and import duties, and thus check not only local consumption but importation also. The result is over-production of a wholly injurious kind leading to glut of neutral markets.

THE rejoinder has often been made—and the Board of Trade places it in a prominent position—that it is of great advantage to England thus to obtain at exceedingly cheap rates what is widely consumed as a food, and what is more and more becoming a raw material of several industries. This is incontestable; but the question remains, at what cost do we obtain this undoubted advantage? The falling off in the yield of the tax on sugar incomes would tell us some of the profits the nation has to forego in order to secure the £5,000,000 advantage. These alone may be found to exceed it. Such losses result partly from the ruinous uncertainty caused by the very existence of so arbitrary an interference with prices. This checks investment in the industries concerned, and also forces those already engaged in them to demand higher present profits in view of the uncertain future. Other evil consequences are the checks placed on the legitimate expansion of the industry, and the actual destruction of capital invested: when, for instance, a plantation or a refinery has to be thrown out of work. The evil effects extend to other trades, not only those more directly concerned, as the making of machinery or the carrying trades, but even to the general export trade of the country, because the people who provide the bounties have, to that extent, less money wherewith to make purchases. These are some of the evil effects that represent the cost to England of this advantage of £5,000,000 per annum, but there remains one general effect which has not yet received the attention which it undoubtedly merits: owing to the bounty system many in England are compelled to use that sugar which it costs most to produce.

THE task has not yet been definitely undertaken of discovering what is the actual average cost of the production of beet and cane sugar respectively. Nevertheless, such information would be of the highest value and point. I have visited various cane-growing countries, and taken every opportunity of going over estates, and discussing matters with owners, managers, and workmen. I always told my object, but also explained I should never divulge information which was, after all, their own property. I have thus obtained a fairly accurate estimate of the cost of production of cane sugar. This varies greatly with the circumstances of each estate, and especially with the kind of sugar made, but I claim to know, with sufficient accuracy, for political purposes, what it costs on the average to produce the leading types of cane sugar.

It was a far more difficult matter in regard to beet sugar, but I am much surprised at the results of a great deal of evidence I have gathered. It would be of the greatest advan-

tage if full evidence on this subject could be acquired. I commend this task to the Board of Trade, as a fit and useful subject of inquiry and report, by our Diplomatic and consular staffs abroad. The conclusions at which I arrived, and which may properly and profitably be made public property, are that cane-sugar can be, and already is, produced at less cost than beet sugar. This latter is now produced with a perfection of process which it seems certain cannot be materially improved upon, but this is not the case with the bulk of cane-sugar. Nevertheless, even under present conditions, so far as I can learn, cane-sugar, is produced at a cost less by some shillings the cwt. than beet sugar. I therefore hold, after due inquiry, that in so far as the bounty system compels the use of beet sugar, in so far it compels the use of that sugar which it costs most to produce; and I ask can there be a balance of good in this?

WE have thus arrived at two new points in this attempt to define the evil. In the first place, the present low prices of sugar have been largely caused by an over-production directly traceable to bounties; and, in the second place, this over-production is likely to continue so long as Continental growers can prevail on their Governments to make up to them any losses out of the uncomplaining pockets of ignorant tax-payers. All this is, on the whole, injurious to England; it also does great injury to the nations which allow bounties.

IT is perhaps one of the main distinctions between English and Continental history, that in our island the tax-payer has always exercised his voice with effect, whereas this has not been the case in any single Continental nation. We may be singular in our notions; we may be despicable as shop-keepers; but we seem to have for centuries ingrained in our dispositions a jealous and close care of the family till. Ever since money became a medium of exchange, and services to the State became convertible into money payments, there has developed in our midst a prerogative, not only claimed but exercised by every individual, to make no such sacrifice except of his own free will. It is true we "freely grant" a national revenue of a most liberal character—we give £20,000,000 when we abolish slavery, and we do not hold our hands to rescue captive missionaries in Abyssinia or send relief to Gordon—but it is all done with the conscious consent of the individuals who contribute the revenue. It is this national idea which lies at the root of our commercial prosperity. But on the Continent we look in vain for the voice of the tax-payer. Statesmen nominally have it all their own way, but in reality—in some cases consciously, and in others not—they are twisted round the little fingers of vested interests or selfish schemers.

WE have to thank Mr. C. S. Bayley, C.S., Under-Secretary to the Government of India, in the Revenue and Agricultural Department, for the following valuable note by Assistant Surgeon Abdul Rahim Hakim, Khan Bahadoor, Assistant to the Political Resident, Persian Gulf, on the subject of the care and culture of date trees and fruit:—In districts where date plantations are large and on extensive scales, the cultivators do not think seriously of the comparatively small loss, caused by the depredations of wasps, sparrows, crows, bulbuls, &c., on the sweet date fruit while forming on the palm, and as a rule do not provide against sugar-loving insects and birds, and grudge them not a share of the fruit. They say that in the good old times the cultivators were more liberal-minded, when the export trade of the date to European countries and America did not exist, and those countries had not acquired a taste for this fruit; that then any number of strangers could go to a plantation and treat themselves *ad libitum* to any quantity of date fruit they liked, without objection. But times have changed. The demand for the fruit, having largely increased, it is more taken care of, and strangers are not allowed to indulge in those liberties.

It is interesting to note that all this is in accordance with the encroachments of the aforesaid nations on the liberty

attributed to their alleged magnanimity and charitable feelings for them—at least in these days when the fruit has a market value; but that their indolence and the actual difficulty, perhaps costliness, of the measures to provide against these inroads must explain a great deal. The ordinary wants of these people are few and simple; they are satisfied with what little they get, and are content to live on the same: as a result their inventive faculties are not taxed for devising means against such sources of loss, which certainly cannot be considered of no moment. But if the case was otherwise, and the struggle for life was as great as in European countries, protective measures would doubtless be fast forthcoming, simply because "necessity is the mother of invention." In places where the date palms are few, and some choice dates are concerned, the date bunch is put into a gunny bag and the mouth of the bag closed up and tied securely at the lower part of the date spadix, to prevent the depredations of those insects and birds. At Bustak, Gowda, Jenna, and other inland districts on the Persian mainland, where dry hot winds prevail, the cultivators allow the fruit to ripen and dry on the palm, and with a view to protect it from the injurious effects of very dry and hot winds, as soon as the date has become sweet, but before it has commenced to soften and become juicy, they wrap up the whole bunch, the stalk of which being already sufficiently bent down for purposes of easy manipulation, in the leafy twigs of a perennial bush called "salm," and, securely tying the leafy covering, leave the bunch until it is finally cut down when the date has ripened and formed. This method gives also a good deal of protection against the inroads of birds and wasps.

.

In some districts, as those of Minab, sometimes bears prove destructive to the fruit; but the cultivator effectually provides against their climbing up by tying a quantity of some thorny bush or twigs of samr (thorny acacia) or konna (zyzphus) around the stem of the palm, at some height from the ground. Against a flight of locusts he is perfectly helpless; all his attempts at driving them away, by beating about among the palms with dry date leaves, and agitating them to cause a rustling noise, &c., and his burning quantities of hay, tamarisk branches, and other rubbish to create smoke, prove of little or no avail; as, when the locusts alight and squat, they completely devour the fruit and leave the palm, in a short space of time, divested of its leafy appendages. There are two principal forms in which the date fruit is cured and prepared for commercial purposes,—viz. (1), "khoorma," soft and juicy; (2), "kharak-pokhta," dry and firm.

.

The following is the usual mode adopted for preparing "khoorma" for commercial purposes:—As soon as the dates become ripe and juicy, they are picked off the tree and gathered into a round chunam tank called "madibah," where they are exposed to the sun and air, and throw off the excess of juice which runs through the aperture at the bottom of the madibah, and collects in a separate jar buried underground to receive it. After two or three days exposure, when the date has sufficiently hardened and formed, it is removed, and packed in date-leaf baskets for exportation. Sometimes, when the owner does not find a ready purchaser, he stores the date baskets in a close-plastered room called "kandool" in piles of 15 to 20 baskets; the floor is furnished with channels which convey the juice thrown off under the mutual pressure of the bags, to a large jar buried underground. Sometimes the juice is slow in draining, then the cultivator encourages the flow by pouring a little warm water on the dates while they are in the madibah. But the dates thus treated and forced to give up their juice lose their taste and commercial value, and are not so much esteemed as those which are simply dried.

.

The best method for curing dates is the following:—The fruit, as soon as it has become "ratab," i.e., ripe and juicy, is picked off the bunch, and spread in an enclosed spot of ground called "mush," which is previously well tamped to render it firm, and swept clean to prevent the fruit from mixing up with the dates; or, better still, they are exposed to dry on

date jowlies spread within the "mush" from three to five days, and then collected and packed in baskets.

.

The following are principal varieties of dates which are cured in the above method:—At Busrah and Mohammurah.—Guntar; Khadrawi; Hallowi; Baraim; Dairee; Shakar; Sa'ameran; Kabkab; Zahidee Sayer. Sometimes small quantities of the following dates which are rare, and usually consumed in the fresh Kharak stage, are mixed with the above:—Barhee; Jowzi; Loolooi; Khassab; Hamrawi; Firsee; Shirsi; Asgar, &c. At Dashedi.—Seesee; Khanaizee; Zynadheoni; Kaap; Kabkab; Kandi; Shakar; Guntar; Hallowi; Muktoom; Shaikali; Kharoo; Sheereeni; Jowzi; Shalooni; Kaidi; Rash, &c. At Datinah and Oman Coast.—Musalla; Salani; Khanaizi; Hilali; Khassab; Maisali (principally made into Kharak); Barani; Sarashi; Maznaj; Fardh; Khamri; Naghal; Khalas; Abunaranjah, &c. At El Hasa, Kateef, and Bahrain.—Khalas; Khanaizi; Marzaban; Hilali; Khassab, &c. At Minab, Bunder Abbas, and Shamilat.—Khanaizi; Murdasang; Hilali; Marzaban; Azad; Zarrak; Sahkari; Abdandan; Mandal; Kalak Soorkh; Malak Soorkh; Shaikh Kamali; Dang-Safeed; Chattan; Hallow; Ali-mehtari; Soorkh-dang; Mosalli; Mosalla; Naghal; Shahri Sa'ameran, &c., &c. There are other varieties not well known, and are comprised under the general term "Kharoo."

.

At El Hasa the best dates, principally Khalas, are packed in skins of 70 to 120 pounds for export. So also at Busrah, dates are packed in skins; the dates are packed for the purpose; the skins are then allowed to dry in the sun, and covered with gunny. At Bahrain and Kateef, Khalas and other dates of superior quality are put in small earthen jars, and rendered palatable by adding to them small quantities of sesame seeds and ginger powder; the jars are then sewn up in the date-leaf matting.

.

Now, since the European and American firms have commenced to send dates to their own countries, they have adopted the system of packing the best dates—i.e., Hallowi, Khadrawi, Zahedi, and Sayer—in deal boxes of various shapes and sizes, brought ready made from those countries. The average size of a box is about 45 pounds net weight. Hallowi dates are also carefully packed in small card-board boxes, 10 to 15 of which are then put in a large deal box, which is then nailed over. The best dried dates of sound skin, and specially those which are allowed to dry on the palm, are carefully picked by a large number of labourers, principally women, boys, and girls, employed for the purpose. A certain weight of dates so picked intended to go in a box is taken; the dates are then carefully placed, one by one, in rows, so as to form layers in the box, which is lined with paper, and eventually nailed and ready for export. Some people put hoops round the boxes, and cover them with gunny, while others do not. These layers are pressed down three or four times during the filling of each box. The dates packed in boxes in layers throughout have now the best repute in the market. Small quantities of dates have lately been shipped from Busrah in fancy baskets, but on account of the heavy freight, no sanguine hopes are entertained of this method proving a success. Hallows keep best, but Zahidis are the brightest in colour, but soon get wormy and spoiled.

.

The cultivator has other modes of curing fresh dates and making preserves of them in small quantities for his personal use, and for presents to his friends, and even for sale to a small extent. "Khoorma-Sheerah" is generally made of Murdasang and Khanaizi dates. The best dates are culled and further well dried in the sun, exposed on mats or date jowlies, and protected during nights from dew. They are then washed with diluted date juice of all dates, and put in a jar mixed with sesame seeds, ginger, walnut kernel, &c.; a quantity of good date juice is poured in so as to cover the whole. This is much prized by the natives. "Khoorma Seli-Raza," so named from its being fit to be eaten on the third day of its being potted. It is a rare and

special preparation made at Minab from the Hilali dates. The fresh "ratab" is taken, its skin is removed by the date-leaf spine; then the coarser but soft layer of the pulp; finally, the white firm pulp which is left round the stone is further detached, and collected in small earthen pots. The mass is rendered more palatable by adding to it a quantity of pistachio and almonds &c. This is considered a great delicacy. "Khoorma Post-kandah," the skinned date.—This can be prepared from all the good varieties of dates, but it is generally made from the Hilali. As above, the skin of the fresh "ratab" is removed by the date spine; the stone is pushed out by the same; the fleshy part is gathered, and packed in large earthen pots. "Moorabba Khoorma" (date preserve).—The ripe "Kharak of Hilali," i.e., before they have become "ratab" (soft and juicy), are taken; portions from both ends are sliced off: they are then deeply punctured all over by the date spine and well dried in the sun. The stone is sometimes replaced by almond or pistachio. The "Kharak" thus treated is boiled in sugar syrup to a sufficient consistence, and forms an excellent preserve, and may be bottled and kept for any length of time. "Matgooghah."—The sweet and fresh "Kharak" is broken up and dried in the sun for five or six days. It is then pounded in a wooden mortar; the powder is put in boiling date juice, and mixed with sesame seeds and flavoured with cardamoms, cinnamon, &c. The whole mass is then well stirred while boiling, and removed from the fire, and further well mixed up, and finally put in jars for use.

**

The second form in which the date fruit is cured for commercial purposes is the "Kharak-pookhtah," the boiled date. It is prepared as follows:—When the "Kharak" has become sweet, but before it has begun to soften, the spadix, with its load of dates, is cut off from the palm and immersed in larger copper pots of boiling water, in which it is allowed to remain for a time, which is decided by the man engaged to do the work. It is stated that the boiling is continued until the stone assumes a reddish colour; when the bunches are removed and exposed to dry in sun on mats for eight or ten days; they are then detached from the spadix, allowed to dry further, and finally put in bags for export.

**

The fruit of all the varieties of the date palm can thus be converted to "Kharak-pookhtah," which is dry, firm, and even hard, and does not relish so much as the "Khoorma," which is soft and juicy. This may perhaps account for the small quantity of "Kharak" usually prepared. At Busrah, "Kharak-pookhtah" is prepared in small quantities from Baraim, Sa'Amiran, Kabkab, Maktoom, and Shakar. Baraim yields the best quality, and is said to be wholly converted into Kharak, as it does not ripen beyond the "Kharak" stage, its price being two or three times more than that of Sa'Amiran Kharak, which is also abundant. The best "Kharak-pookhtah" of Minab is from Hallowi in small quantity, but principally from Zarak and Sayer. At Lar and its neighbourhood a "Kharak-pookhtah" is obtained from the Sha-Khani date. As soon as the fresh Kharak has been sufficiently boiled, it is taken out of the water, its stone removed, and it is strung in long wreaths and hung up to dry; it is yellow, and of good taste. From various causes a portion of the date-fruit does not attain maturity, and generally drops off in a half-ripe state; becomes dry, skinny, with very little flesh. In this condition it is called "Salang," and used as food for sheep and domestic cattle; sometimes it is boiled with date stones, and constitutes a nutritious food to the milch-cow.

**

The age of an off-shoot is no reliable guide for its being detached from its parent for purposes of a successful transplantation. An offshoot sometimes continues at the foot of its parent several years, but under the various and variable circumstances of soil, supply of water, &c., it is small and weak, and therefore unfit for transplantation, while under favourable circumstances an offshoot, 3 or 4 years old, is vigorous and large, and does not usually, when transplanted, lose its root and

survive. Hence the vigour of growth and the actual size of the young plant are taken into consideration. The average weight of the young plant most suitable for purposes of transplantation is considered to be six pounds; but larger weights are preferred, as, after striking, the plant grows rapidly, and bears fruit without much trouble and expense to the cultivator. It is averred that sometimes offshoots which have commenced to bear fruit are carefully detached and successfully transplanted. The *Phoenix dactylifera*, or the Arabian date palm being dioecious,—i.e., the male and female flowers existing on separate plants,—the conveyance of the pollen to the female flowers is essential to fertilisation and formation of the date fruit. The agency of winds and various nectar-loving flies and insects does not seem to be sufficient to effect the necessary fecundation, as in such cases, the fruit yielded is stated to become abortive or blighted, with little flesh, without stone, and totally insipid, and is termed "Shis." Consequently, human agency is considered essential for a fruitful impregnation.

**

The male spathe, as soon as it has attained its full size and maturity, which is known to the cultivator by certain signs and indications, such as a faint rustling sound, elicited when the central part of the spathe is gently pressed, or a peculiar seminal odour, detected by making a slight indentation in the marginal part of the spathe, so as to expose the flower, which is cut at its root and taken down. The enclosing spathe is slit open, and the flower-sprigs are gently detached from the spadix, and carefully preserved in a basket, which is suspended in a spot protected from drafts of wind; the sprigs are allowed to dry for 20 to 24 hours before being used.

**

As soon as the female flowers have split open the spathe under their growing pressure, the cultivator considers it time to commence the operation of fertilisation. He takes the flower-twigs of the male palm, and deposits one or two in each bunch of the female blossom, lightly binding it up with a strip of date leaf. If the cultivator finds that some of the larger spathes have not split, to save him the trouble of reclimbing, he slits them open and deposits the flower-sprigs in the blossom, as before. Only very small ones he leaves untouched, to be attended to, if necessary, subsequently, when they have attained maturity. But, as a rule, he does not allow all the flower-spathes, which vary from 12 to 24, to remain on the palm and form fruit, because by doing so the fruit becomes small and degenerate, and during the next year the yield of the fruit is lessened. According to the vigour of the palm, which he knows by experience, he leaves 8 to 12 bunches to form fruit. The excess is removed and consumed by his people and friends. The sprigs of the male flower are preserved in a dry form one or two months, and used as occasion demands. They are, however, before being used, slightly moistened with water to prevent the pollen from being scattered and blown away by the wind. It is stated that sometimes, when the male flower is not in sufficient quantity at "Kharg," the cultivators import it from Busrah. Pollen of one year cannot, it is stated, be preserved for use during the next year, as it becomes spoiled. When the female blossom has thus been treated with pollen, the supply of water is cut off for a time, varying from one and-a-half to two months, as excess of water is said to be detrimental to a proper fertilisation. The general method adapted for cultivating the date palm in these parts, where it is grown for economic and commercial purposes, is that it is planted in extensive groves for facilities of tending them and collecting the fruit. Spots are selected where abundance of water is available in shape of river, spring, "kanat," or well water; in other places, where water from wells is scanty, such spots are selected as can be irrigated by rain-torrents during the rainy season.

**

A tree of ground is selected according to the number of palms which it is intended to plant in a grove, which may consist of 80 to 100 or 200 palms, planted in regular rows, with a distance of 12 to 15 feet between them. The grove is surrounded by a high "bund"

for purposes of admitting and retaining water in the grove, and generally regulating its irrigation, being provided with inlets and outlets to admit and get rid of excess of water, especially that from rain-torrents. For the first two or three months, after the offshoots have been planted, they are watered, each separately, by water carried to them in pots; great care is taken that no mud gets into the heart or crown of the young plant, as it proves destructive to it. After the plants have struck root they are watered once a week, a fortnight, or a longer interval is allowed to elapse, but it is essential that they must be well watered once month. When they have grown up and have attained some age, they are watered once a month during the hot months only. At Busrah, where water is abundant from the river, deep and wide trenches are dug between the rows of the palms, and filled with water. But where water is scanty it is allowed to run down in small channels to the foot of each palm, the ground being previously well dug up, loosened, and turned over to allow of its thorough saturation.

.

VEGETABLES, lucerne, &c., are grown, as at Bahrain, in these groves, such a cultivation being considered highly beneficial in improving the soil. With this object also the soil is ploughed and turned over once a year to render it soft, porous, and permeable to air moisture. In places which border the sea, fins of awal or lookhm, a species of ray-fish, are used for purposes of manuring the palm; two or three bits are buried at the foot of each palm, and it is regularly watered once or twice a week until the whole is absorbed and disappears; or these fins are put in, and allowed to macerate in the tank of water which feeds the plantation, and the palms are regularly fed by water so impregnated. In other places where this is not available, the dung of the cow, sheep, and goats, &c., and surface sweepings are used.

.

THE best spot for extensive date plantations would be, as at Busrah, Mohammerah, and Minab, along the river banks abounding in alluvial soil. Excess of water generally is said to spoil the date fruit, and if the plantations become flooded and continue so any length of time by any very unusual rise of river waters, not only is the fruit damaged, but the palms have been known to die. So also damp air, when the fruit is forming, is said to be prejudicial, as a great deal of it drops off in a green state; this green date is called "Khamal," and is given to sheep and cattle, but the poor people consume it with fish. Moderately dry winds are said to be very beneficial. To secure a vigorous growth to the palm, as also to obtain materials for economic purposes, the following points require to be attended to. As the date palm grows each year the lower whorls of the leafy stalks, as their vitality diminishes and they become dry, are chopped off; the long stalks called "Goory" are made into jowlies for covering sheds, roofs of houses, and various economic purposes. Their lower thick ends, called "tapool," are used for fuel, but those which are broad and light are used as floats for fish-nets.

.

THE flower spadix and its spathe must also be removed. The green spadix, when well beaten with billets of wood, yields a quantity of fibre useful for rope-making. In a dry state it is used as fuel, but if allowed to macerate and soften in water on being pounded between billets of wood, yields fibres for ropes. From the fresh spathe, called "Tara," is obtained the "Tara" water, by distillation. It is of a strong but agreeable smell, and is prepared at Busrah and Bahrain; sold in carboys at one and a-half to two rupees each. It is made into a sherbet, and is greatly prized by the Arabs and Persians. The young offshoots sprouting at the base of the palm, if they are not intended for transplantation, must be removed in the spring of each year, as they prevent it from thriving. In the same way the buds, which sometimes form and grow from the crown of the palm, resembling the offshoots at the base, must also be pulled away, as they weaken the palm. These buds are sometimes said to have grown, and yielded fruit, when intended to grow on the palm.

EXPERIMENTAL CULTIVATION OF THE NATURAL KHAKIE-COLOURED COTTON.

SOME very interesting experiments have been made with the seeds of this cotton in several of the districts of Bengal, which have just been published by order of the local Government. In the district of Bankoora the seed was sown in the Collector's garden. It germinated in the course of time, and the plants, while 2½ feet high, yielded a few pods like ordinary cotton, in the month of February 1884. The plants were allowed to grow on and are now four feet high. They are expected to bear again next month. In the district of Hooghly the seeds were distributed to five wealthy zemindars, and it is curious to note what varied results attended the sowings within a radius of a few miles. In Otterparah, a small village six miles from Howrah, three experiments were tried. In one instance the plants gave promise of healthy growth, but after they were about six inches high they decayed and died out. In another instance some cotton was grown, but it is reported that owing to the moist character of the soil of this part of the country, the stalks do not grow large, and the colour of the cotton is affected. In the third case the plants came up to a height of about a foot, but soon after died out. In Jonai, the quantity of cotton produced in 1883, was small, due to late sowing, but the quality was fine. Some seeds were sown in 1884, and the luxuriant growth of the plant promises a good out-turn. One of the zemindars caused some seeds to be sown in his estate in the district of Rungpore, out of which only three plants have grown to a height of eight or nine feet, but not an ounce of cotton has been recovered. A piece of cloth and some of the yarn worked up from the Khakie-coloured cotton, by the officer in charge of the Hooghly Jail, have been forwarded to the local Government for inspection; an other piece of cloth has been retained in the jail, when the fastness of its colour will be thoroughly tested. There was a complete failure in the Chittagong Division where the seeds were sown both in jooms, and in lands duly ploughed and prepared. The seeds germinated in every case, but the plants gradually died out. The failure, however, is easily accounted for; the ordinary cotton is sown in the district in April and May. The seeds in question having reached the Deputy Commissioner in July, it was too late to undertake the experiment with any hope of success. A fresh trial will be made this summer. In Monghyr, the plants which grew in General Murray's garden last year were nearly all eaten up by insects, and a few pods of the last season have been sent as specimens for inspection. The new plants are 11 months old and in a flourishing condition. A large out-turn is anticipated. A quantity of nine seers and five and-a-half chittacks of cotton was produced from plants which grew, from a quarter of a pound of the seed sown in Maharaja Shew Prosad Sing's estate. The plant is not new to the district.

In the district of Bhagulpore a few seeds were sown in August 1883, in the sub-division of Soopole, which germinated freely; but the plants were eaten up by insects. Finally the bulk of the seed was sown in October, but owing to untimely cessation of the rains in September, they did not germinate, and the few that did come out died from want of moisture. The Collector has received a quantity of the seed from Cawnpore for further trial. Baboo Hari Mohun Thakoor made the experiment in his own garden, the soil of which is believed to be suitable for the cultivation. The plants there are in good condition, and beginning to flower. In the Southal Pergunnahs, a quarter pound of the seed was sown at each of the two places, Jamtara and Godda. The Deputy Commissioner says, "the seed was very old, and only about one-third germinated. Some of the produce was of a very dark colour, some white, and some light."

In the Orissa Division, the crop raised by Mr. Taylor in Khorda, in the district of Pooree, was destroyed by cattle. The experiment will be repeated with some seeds Mr. Taylor has managed to procure. From the reports received by him, the Commissioner finds the climate of Orissa to be favourable to the growth of this cotton. He expects a good outturn from proper cultivation. The cotton, however, is liable to hybridisation, and the destruction of the uniformity of colour. The Collector of Burdwan (Mr. Headon) reports: "I received the seed in July 1883, and immediately sowed it in boxes, but owing to heavy

rain and flood did not transplant till late in September, as I was afraid the damp soil would be too much for the young plants. A great many of the seeds did not germinate, which I attribute to the bad quality of the seed itself. Out of 69 plants which I reared, 13 died on transplantation. The survivors grew very rapidly, and began to throw out buds almost immediately. The cotton ripened and was plucked in January, February, and March, and gave an out-turn of seven pounds without seed, or an average of two ounces per plant. I watered the little bushes for a short time after transplanting, as owing to the early cessation of the rains there was little moisture in the ground. I presume it would not be necessary in an ordinary year. Almost immediately after plucking in April, the bushes began to flower again, and fresh pods formed, but as soon as the rains commenced they rotted and fell off the bushes. Since the rains the bushes have made tremendous growth, and are now 4 to 5 feet high, and though originally planted 3' x 3', are touching each other and overcrowded, and the little plantation has a dense appearance. There are now plenty of buds on the bushes, and some are already in flower. They should yield well in the cold weather. The soil is the ordinary dark-coloured sandy loam which prevails to a great extent in this part of the district. I can get no reliable data from the natives close here regarding the out-turn of the ordinary country cotton; but those who have seen the plants grown by me seem to be of opinion that they would give the larger out-turn."

In the Chota Nagpore Division, the Superintendent of the Hazaribagh Jail sowed two acres of prepared land with half a pound of the seed, in the beginning of October 1883, in drills six feet apart. Only about 100 of the seeds germinated and formed plants. He caused them to be weeded and watered twice a week. The plants are still very small; only about eight inches high, although some of them are now in flower. The Superintendent intends to make another trial this year, and has therefore asked for some more seed. The District Engineer has collected a quantity of seed from the last crop, and this will be made over to the Superintendent.

The Superintending Engineer, Hazaribagh, received half-a-pound of the seed on the 29th July 1883, and sowed them in shallow boxes placed in the shade. Most of the seed germinated within a week. As soon as the plants, about 250 in number, grew up to be sufficiently strong to withstand heavy rain, they were transplanted and put six feet apart on prepared ground, in the road cess office compound, by the third week of August 1883. Earth was then heaped up round the roots of the young plants. They were watered twice a week during the cold season, and four times a week during the hot weather. The first crop yielded 14 pounds of cotton. The shrubs are now again in flower, and will shortly yield a second crop. They are gradually becoming bushy, though the tallest plant is not more than three feet high.

A sample of the cotton grown in the garden of Mr. Frizoni of Hazaribagh, has been received. The sample appears satisfactory to Mr. Hewitt.

The Deputy Commissioner of Lohardugga reports that the Assistant Commissioner of Palamow distributed seeds to three of the zemindars of his sub-division. In two cases the experiments failed, the plants dying after attaining a height of 9 inches. In the third case, the seeds were sown in the latter part of October 1883, and the plants have since grown up to a height of two feet, and have commenced to flower and bear pods. The Assistant Commissioner thinks that the seeds have not had a fair trial, and asks for a further supply.

In the head-quarters sub-division the experiments made by the ryots and Mr. Peppe were unsuccessful. The Deputy Collector, Baboo Mohendronath Mookerjee, made three experiments, two of which failed. The last made in September proved to some extent successful. The seeds were sown on soil "loose and deep, neither dry nor clayey and stiff, and under the favour of alternate sunshine and cloud the seeds germinated quickly, and 90 per cent came out successful, but the plants appeared weakly and many died out, and after several casualties, about 50 per cent survived to put forth leaves, 40 per cent flowered, and 25 per cent gave pods."

At Marbhoom the pound of seeds received was sown broadcast by Dr. H. W. Hill. Only a small portion of these

germinated, and the cotton produced was small in quantity and of a brownish-red colour. Dr. Hill thinks that the khakie cotton is a hybrid between *Gossypium herbaceum* and *Gossypium herbaceum*. He says that a species of this plant, if not indigenous, is cultivated to some extent in parts of Patkom and Burrahoom, and chiefly by the Sonthals, who call it *khureeah kapas* in contradistinction to *kurawah kapas*, or white cotton. The colour of the latter is that of the khaki cotton experimented on, and the Sonthals spin and weave it into a sort of coarse cloth. The species found in the district is considered by Dr. Hill to be a hybrid of *Gossypium herbaceum*.

Miscellaneous Items.

THE planters of Fiji are considering a scheme for importing Tamil labour for their estates.

THE exports of tea from all China amount to 123 millions pounds, against 139 millions last year, to England alone.

THE net Indian sea and land customs revenue for the first eight months of the current financial year amounted to Rs. 53,42,000, as compared with Rs. 65,61,000 in the corresponding period of last year.

WE understand that all the shares, amounting to Rs. 4,00,000, of the Poona Deewan Paper Mills Company (Limited), are taken up. The Company will now be registered, and allotment of shares made within a short time.

THE Christmas rains are apparently absent in Lucknow, for, with the exception of a few drops lately, the fall holds off. A good shower would be of inestimable value to the crops just now. There is a general barometrical depression over a large area of country, and rain is generally looked for.

A SUPPLY of mangoes was exhibited for sale in the fruit bazaar, at the back of the Bangalore New Market, on the 21st ultimo, and they were readily bought up by the butlers. It was singular to see mangoes at this season of the year; but we were told that they were imported fruits. It is a pity, says a contemporary, they were not kept for the Show on the 24th idem.

THE news comes from Australia of the arrival at Melbourne of a shipment of Java teas. It is said that the Java planters have determined to create a market for their teas in Australia, and propose to set about devices to "popularise" that article. This intelligence will hardly be received with satisfaction by the Indian tea-planter who has been attempting for some years to popularise Indian tea in Australia.

THE latest use to which it has been found possible to put paper is for making the floors of skating rinks. Straw boards are first pressed together under a hydraulic press, and when seasoned and dried, sawn into flooring boards, and fixed edge upwards. The surface is then sand-papered until it becomes as smooth and slippery as a sheet of ice, but yet it is said to be so adhesive that the roller does not slip upon it.

THE Government of Bengal has authorised the payment, by the rangers and foresters in charge of sixteen revenue stations in the Sunderbuns Forests Division, of an extra reward of Rs. 25 for each full grown tiger, and Rs. 10 for each tiger cub that can be proved to have been shot, or destroyed in any other way, in the Sunderbuns reserved or protected forests, in addition to the authorised rewards payable by the district officers.

A GENTLEMAN, named Aulfray, has just made a discovery which is likely to confer a great benefit on the dwellers in Mauritius. He has discovered a method of producing sulphate of quinine from the bark of cinchona, which grows abundantly in the islands, and his process is said to be both cheap and simple. Considering that for some years past the colony has expended Rs. 1,10,000 in the purchase of quinine from abroad, the value of the discovery is likely to be thoroughly appreciated.

WE regret to learn that at Sholapore, Kaladgi, and the country immediately adjacent, there is a failure of crops to the extent officially known as "a scarcity." This is attributable to the want of dew. The Government have already taken steps for the remission of revenue, and it will probably not be necessary to open relief works, as owing to railway facilities there is a good supply of grain. The condition of these districts has, nevertheless, occupied the close attention of Government.

A FEW days ago a Malay at Pangeran, while walking along, a narrow path through a swamp, came in contact with a python, which, after biting his leg, coiled itself round it; he had however presence of mind enough to seize the reptile by the head, and by forcing its jaws open until they were dislocated, disabled him. On arriving at the village the man was given, and the people turning out, found the snake, which had crept into the scrub, and speared it. It was 18 feet in length, so the man must have had

THE Government of India are bent upon the rapid development of the Umaria coal fields in the Rewah State, which are expected to yield a large supply of excellent coal. The railway from Kuntui on the Allahabad-Jubbulpore line to Umaria will be completed as quickly as possible, and the coal thus be brought within easy reach of consumers. Mr. Hughes, of the Geological Survey, an expert in the matter of Indian coal, will, as we have already stated, direct operations at the coal fields during the next twelve months, and will direct the mining operations in a scientific way.

The following account of a rather remarkable hen is given by a correspondent of *Land and Water*:—"She is a cross between a Game hen and a Brahma cock, and was hatched in May, 1882. She commenced laying in January of the following year, and laid 189 eggs within the twelve months. This year she has laid 156 eggs, and is still laying. I may add that she is quite a Cookney, having lived on the leads of a public office for the last two years, her owner being the hall porter. She is very fond of lying before the fire, stretching herself like a dog. At meal times a chair is placed for her at the table, her food being washed down with a liberal supply of stout. Possibly it is the latter, combined with the warmth of her quarters, that has caused her to lay so well. The most curious thing is that a great number of the eggs have been laid in the lap of the porter's wife."

The officers in charge of the Commissariat Department, Jellapahar, recently opened a silo. Six were constructed about five months ago by excavating earth to the depth of six feet. They were about 12 feet long by 12 feet in width. After they had been filled with grass in a very damp condition, the grass was well trodden down, a layer of mats and planks was placed on the top, and pressure given by six feet of earth heaped up with a slight slope on all sides. After the earth and planks, &c., had been removed, the grass in the silo opened was found to be of a greenish yellow colour, and the smell emitted was so disagreeable even for a depth of three feet that, as far as this silo is concerned, the trial is a failure. Even when sprinkled with salt after an exposure of nearly eighteen hours, hungry cattle ate barely half the quantity offered them, and this with little or no relish.

Selections.

FIBRE-EXTRACTING MACHINES.

The following report of Messrs. J. W. Hanlon and L. Liotard, on the competition of machines in the extraction of Fibres, held in September last, will be read with interest. We defer any remarks of our own until the Government Resolution thereupon is published in the local Gazette:—

TO THE SECRETARY OF THE GOVERNMENT OF BENGAL, Revenue Department, Calcutta the 24th November, 1884.

SIR,—We have the honour to report on the competition of machines in the extraction of fibres. Nine machines were entered for competition. These will be described briefly in the order in which they were placed in the shed erected for the purpose of the trials.

I. A machine patented by Monsieur Berthet and constructed by Messrs. Talpin Freres et Cie of Rouen. Account of the Machines. This machine was brought to Calcutta by Sir Walter de Souza and entrusted

to Dr. King, Superintendent of the Royal Botanical Gardens, Howrah. It is a large machine, rather straggling in appearance, and of ingenious, though not very efficient, mechanism. The principal parts are a couple of large drums carrying gun-metal scrapers. To keep the plants up to the scrapers each drum is fitted with an adjustable curved wooden block. The plants in the first place are fed to a set of rollers which operate upon the whole length at once, that is, the stem is placed parallel with the rollers. As the rollers are only about 4 feet long, most of the plants had to be cut to suitable lengths. After passing through the crushing rollers an endless wire rope carried the crushed stems to the beaters. First, one half is scraped at one drum, the cleaned end is then picked up by the endless rope, and the other half is carried past the other drum; finally, what is left is removed automatically from the rope before the latter passes again to the crushing rollers. This feeding arrangement did not work with any certainty. The cost of the machine is unknown.

II. A machine invented and patented by Mr. R. R. G. Hatti Boroah a native gentleman of Upper Assam. This is a simple mechanical arrangement, consisting of two pairs of smooth wooden rollers on iron spindles, set in a line in a vertical frame. A spur wheel is geared to both sets of rollers, and motion is communicated through a set of bevil wheels by a horizontal shaft carrying the usual fast and loose pulleys. The machine is faulty in design, and is said to cost Rs. 300. Stems are passed through the rollers several times, and washed nearly as often, until clean fibre is obtained.

III. An apparatus by Mr. Hatti Boroah, worked by manual labour. This consists of two smooth rollers about 2 feet in length and 6 inches in diameter placed upright and worked by iron spur wheels put in motion by a central shaft, to which motion is communicated by a wooden lever 10 feet long turned by two men. In construction this apparatus is identical with the ordinary native sugar mill, and is said to cost Rs. 50.

IV. Pownall Patent Flax scraper, constructed in Wellington, New Zealand, and sent out to the use of Messrs. Heilgers & Co. of Calcutta. This is a very compact little machine, driven by steam-power. It consists of a pair of horizontal grooved iron rollers placed at the centre top of the machine. Immediately below the rollers are two drums provided alternately with scrapers and faced iron ribs. Below these drums are two smooth rollers of

the same size as the upper grooved ones. The fibrous stems, when put to the grooved rollers, are drawn in and crushed, and then forced between the drums, where, by the action of the scrapers of one drum against the alternate flat bar or rib of the other, the woody part and refuse matter are scraped off. The fibre dropping between the lower smooth rollers is held firm and is brought out underneath the machine. The cost of the machine is unknown.

V. A smaller machine of an exactly similar description by the same owner. This is workable by hand or steam-power. Price unknown.

VI. Another small compact iron machine on the same principle as Nos. 4 and 5, and by the same owner. There is, however, this difference in this machine, that the drums are made of thin plate iron, and so constructed as to ensure a certain elasticity when the scrapers come in contact with one another as the stems are passing through.

VII. A small machine belonging to the same owner as the three last mentioned. This is workable by either manual labour or steam-power. Two small grooved iron rollers crush the stem and push them forward between a wheel four feet in diameter provided with scrapers, and a zinc frame in close adjustment with the scrapers. The stems having been crushed by the rollers, the action of the scraping wheel against the zinc frame removes refuse matter from the stems, and brings the latter between two smooth rollers at the bottom, whence the fibre is taken out.

VIII. Cautwell's patent process for extracting fibre-bearing plants. The patentee describes his process thus: using for this purpose a roll mill patented by him for the expression of sugar-cane juice:—"My patent sugar-cane mill is modified for this purpose (extraction of fibre) by the insertion of a spring or other elastic substance at the back of the crusher or bearings, so as to prevent the fibre in the plant from being crushed or ground in the process of crushing. This can be done in a few minutes by removing the rigid abutment piece used when crushing sugar-cane and substituting for it the spring. The crushing process is primarily intended for endogenous plants that cannot be retted, but exogenous plants are simply crushed one or more times and then retted in water for a short period, varying from two to four days according to the amount of crushing the plant may have received. The exogenous plants having hard woody centres are first crushed, then the fibre part peeled off and again passed through the mill, and then retted for from 24 to 48 hours."

IX. The universal fibre-cleaning machine, invented by Mr. H. C. Smith, manufactured and improved by Messrs. Deane and Ellwood of Leicester, and brought to public notice by the General Fibre Company of London, is a very simple, compact, and well-designed machine. It consists of a cast-iron drum, perfectly balanced, on which eight gun-metal beaters are bolted. The drum revolves in front of a table or feed-plate fixed below the centre of the drum so as to give a scraping action when the beaters pass it. The feed-plate is adjustable to and from the beaters by set screws, so that a fine or thick fibre can be cleaned. Immediately below the feed-table is a jet pipe which throws a strong thin flat sheet of water against the whole width of the drum. These are the essential parts of the machine, and they are mounted on a cast-iron frame, which carries them as well as a trough to receive and let out water, refuse and waste, and to prevent the water being thrown about. Two men feed the machine; each taking from three to five leaves or stems at a time, places the thick ends upon the feed-table and pushes them against the revolving drum provided with beaters. These smash the woody parts of stems, disengage the pulpy matters of leaves, loosen all refuse matter, and by their action draw the crushed stems or leaves under the drum, here the sheet of water presses the stems or leaves against the beaters, a beating and scraping action continues, and the sheet of water acting as a cleanser as well as an elastic cushion or backing to the fibre while it is struck by the beaters, ensures a thorough cleaning. The stems or leaves are allowed to pass half way into the machine, and when withdrawn, all extractive matter has gone and clean fibre is obtained. This is held in the hand of the operators, who then pass and withdraw the thin ends in the same way. The result is clean pure fibre, which is then hung up to dry, and when dry is ready to be baled at once. The cost of a single machine is £55, that of a double one, complete, is £100. A semi-portable engine to work two of the machines is supplied by the General Fibre Company of London for £82-10. On comparatively small plantations, instead of the steam engine, bullock gear can be used which, for a single machine, is supplied at £30 by the Company.

Programme for the tests.

following programme for testing the above

machines:—

15th October 1884,	Jute (<i>Corchorus olitorius</i>).
15th	Sunn (<i>Crotalaria juncea</i>).
16th	Potari (<i>Abutilon indicum</i>).
16th	Bhenli (<i>Hibiscus esculentus</i>).
16th	Joba (<i>Hibiscus rosa-sinensis</i>).
16th	Stolpado (<i>Hibiscus mutabilis</i>).
17th	Plantain (<i>Musa paradisiaca</i>).
17th	Madar (<i>Calotropis gigantea</i>).
17th	Nona (<i>Anona reticulata</i>).
17th	Bon-dheenas (<i>Hibiscus tiliaceus</i>).
18th	Agave (<i>Agave americana</i>).
18th	Dhondha (<i>Scabania aculeata</i>).
20th	Rhea (<i>Boehmeria nivea</i>).
20th	Sansaviera (<i>sansavera Zeylanica</i>).
20th	Meshta (<i>Hibiscus sabdariffa</i>).

Quantities of each of these fibrous plants were brought in on the respective days and were weighed and given for each of the machines to be tested. A note was kept of the quantity of stems given, of the time at which each machine began work, the time at which each finished work, and the weight of the fibre obtained, as also the number of hands working each machine.

3. The following table represents the results of the tests. It will be seen that in the case of some of the machines there has been no result except that of failure:—

Name of Fibre.	Quantity of green stems supplied.	Hours at which work began.	Time of expiry of work.	Weight dry fibre extracted.	Percentage of dry fibre to weight of green stems.	REMARKS.
	Srs.	P.M.	P.M.	Srs.	Per cent.	
Dhondha	10	12-35	The fibres were torn away and destroyed.
Rhea	20	4-6	Failed. The stems glued on the rollers.
No. II.—MR. BOROOAH'S MACHINE, motor power, and 2 men.						
Rhea	5	4-30	4-55	0 8	3-75	This machine was entered to extract only Rhea. The fibre obtained is too much crushed and towey.
No. III.—MR. BOROOAH'S HAND-MACHINE, 3 men.						
Madar	5	12-25	1-21	9 12	1-56	Fibre raddled, tow, with pieces of bark adhering.
Rhea	1	8-5	4-10	0 04	8-12	Clean, but too much crushed and towey.
No. IV.—POWELL'S FLAX SCRAPER (1), motor power, and 2 men.						
Jute	15	1-5	1-25	20 1	3-38	Full of bark and woody matter. Fibre dirty.
Sunn	5	3-53	4	0 11	13-7	Do. ditto.
Bhendt	5	Would not pass thro' the machine: the stems stuck to the rollers.
Potari	5	Fibres torn away. No results.
Joba	2	
Stolpodo	3	
Plantain	5	1-47	1-51	Tore away the fibres.
Agave	10	12-45	1	0 24	1-40	Very insufficiently cleaned; dirty fibre.
Dhondha	2	1	1-12	0 2	5-25	Better than, preceding but still dirty.
Rhea	5	3-52	Stems got clogged among the rollers, fibres torn away.
No. V.—POWELL'S FLAX SCRAPER (2), hand power; 3 men in all.						
Jute	10	1-50	2-15	0 84	..	Failed entirely to clean the fibre. Percentage not worked because of the quantity of wood in the fibre.
No. VI.—POWELL'S FLAX SCRAPER (3), hand power; 3 men in all.						
Jute	10	2-42	2-50	1 2	..	Do. do

* Straight running fibres.

+ Waste fibres.

2. Monsieur Berthet's machine would probably have shown somewhat better results than it actually did, if a competent person had been deputed to work it. Taking the results

as produced, the machine has been found to be both destructive and defective—destructive in that it has caused an unnecessarily large amount of wastage of fibre, and defective in that it has failed to produce the fibre in a sufficiently clean state: woody parts, pulp, and pieces of the bark adhere to the fibres produced, and these extraneous matters, besides depreciating the intrinsic value of the fibres, add to the weight shown in the fifth and sixth columns of the statement.

The fibres obtained from Mr. Borooah's machines were sufficiently clean, but the repeated and excessive crushing to which they were subjected has caused a depreciation in their value, besides giving them a towey appearance. To these defects must be added the very slow rate of out-turn which, in the case of the steam power machine, was 3 chattaks of Rhea fibre in 25 minutes, and in the case of the hand-machine, half a chattak of Rhea in 20 minutes, and 1½ chattaks of madar in 56 minutes.

Of Powell's four machines, not one produced any satisfactory results, notwithstanding the care and attention with which they were adjusted and worked by the agents under whose charge they were. The fibres obtained are conspicuous by their dirty condition, being full of bark and woody matters, and they become brown when drying.

Mr. Cantwell's process produced fibres which are certainly free from wood, bark, or pulp, but the retting has injured the fibres, in that it has rendered them brown. The improvement claimed by the patentee over the common native system is, that the natives by not crushing the stems have to allow them to steep for a period of 8 to 12 days, while he by crushing them in his sugarcane mill facilitates the action of the water while retting, and thus reduces the period of retting to 2 or 3 days. Whatever advantage this may have, it does not, judging from the results, improve the quality of the fibre, or reduce the cost of extraction, while it adds to it the labour and expense of crushing.

Messrs. Death and Ellwood's machine did not work on the days specified above, as Mr. Death, who was coming out to work it himself, was unavoidably detained on the way by quarantine regulations. As the dates specified were not a condition of the tests or of the award of prize, we arranged to have a test of this machine during the following week. The plants mentioned in the above table were supplied on the 28th October, and the fibres were worked out by this machine without a hitch of any kind. Indeed, the working parts are of so simple a character, of such sound material, and correct adjustment, that they leave nothing to be desired. The jet of water plays a most important part in the extraction of fibres; for the stems, after having been bruised by the beaters against the edge of the feed-table receive a very thorough treatment by the beaters on the broad jet of water, and when pulled out they are found to have been freed of all extraneous matters, leaving clean white fibre as the result. The machine is, moreover, as has been proved by the test, capable of treating all fibre-bearing plants, whether exogenous or endogenous with the same facility. A semi-portable engine of 2½ nominal horse-power supplied the motion to the double machine used at the trials. At a rough estimate 1-75 indicated H. P. was expended in driving the double machine at 400 revolutions per minute while at work. As only one half of the machine was used for the purposes of the trials, the other half ran idle. The quantity of water required appears to be about 400 gallons per hour for one machine, but the water can be used twice or thrice over.

Taking the data obtained at the trials as a guide, the out-turn of Rhea fibre from one (Death and Ellwood's machine) would be about 60 lbs. for a day of 10 hours. This assumes a percentage of 3-75 of fibre from 1,600 lbs. of green stalks. The operators were imported and to some extent trained hands, having worked similar machines in Madras, where they were accustomed to manipulate *Sansaviera Zealanica*. Still they did not seem quite at home with the Rhea stalks, and some allowance might reasonably be made on this account. At the outside an increase of one-third would in our opinion represent an average day's work with dexterous and diligent workmen and stalks in good condition. It was noted that the stalks supplied to the machine were not uniform: they were of lengths varying from 2½ to 5 feet; and in withdrawing the fibre of the longer stalks from the machine more waste was beaten out of them than from the smaller stems ranging up to 4 feet. The reason is simple enough; the longer stems were rather too old for the yield of fibre, and had branched owing to the crop from which the stems were cut having been grown rather openly. The addition therefore of one-third would be equal to the work per diem of 2,200 lbs. of green stalks, per machine. This quantity might be expected to give at 3 per cent, an out turn of 66 lbs. of good, clean fibre. The value of this outturn, at £ 50 per ton, would be about 30 shillings.

It should be mentioned that owing to the late date of the trials with this machine, it was not found possible to procure suitable jute stems, as the local crops had already been cut. Some stems, however, which were over from the trials of the other machines and had been lying for about ten days on the ground were tried. The machine cleaned them with ease; but as the stems had been lying exposed to the sun, the fibre obtained was somewhat stained. It is necessary, for the efficient treatment of exogenous plants especially, that the stems should be operated upon as soon as possible after they are cut. The cutting also should take place before the plant reaches full maturity, and the proprietors of Death and Ellwood's machine rightly claim that the juices which contain the various gums and colouring matters in solution are then more readily removed by means of the water used. The trials certainly bear this out, for the wild bhendi or bondheras, which are fully matured and to some extent hardened plants, at the day previous, gave the hardest fibre.

It remains to be settled whether the machine can be worked with profit. To solve this question completely and conclusively, detailed enquiries in various directions and much time would be needed, and we would have to wait for a valuation of the fibres by experts in Europe. It does not seem necessary to us to delay with this object either this report, or the recommendation we have to make, for the following reasons:—

(1) Although detailed statistical proofs are wanting, we have by rough calculation reason to believe that the machine can be worked with profit in this country, especially on jute, rhea, bou-theras or wild bhendi, agave, mansevera, and pine-apple.

(2) The machine is already at work in Mexico, in Jamaica, and several other countries, including Southern India, and yields a profit.

(3) At gardens, in factories where steam is already available, a few machines could be introduced at the minimum of outlay, as the cost of the machine alone would be incurred.

(4) Where water power is available, a turbine can be used, instead of the steam engine. When one machine is worked singly, the patent safety bullock gear supplied by the General Fibre Company can be used.

(5) When natives have gained experience in the feeding and working of the machine, they will probably be able to produce a larger quantity of fibre than at first.

The three last reasons form important considerations in reckoning the prospects which may be anticipated in this country. And as several firms in Calcutta have already made enquiries with a view to making use of the machine, and they seem satisfied with what they have learnt, it does not seem necessary for us to delay our report. We are satisfied that as an extractor of fibres Messrs. Deane and Ellwood's machine is a distinct advance in mechanism of this class, that it extracts fibres in their natural colour and in good merchantable condition, that it operates on all plants with the same facility, and that it is suited to the requirements of this country, and is likely to prove of great service to its fibre industry. On these grounds we recommend that the full amount available for the Government prize may be awarded to the General Fibre Company of London.

We have the honor to be, Sir, your most obedient servants,

J. W. HANLON.

L. LIOTARD.

THE FUTURE OF WHEAT PRODUCTION.

By LIEUTENANT-COLONEL WHEATLEY.

I HAVE just returned from a tour of about 6,000 miles in Canada and the United States, our great competitors in the production of wheat; and as singularly little seems to be known here, even now, as to many important conditions of that production, I will, with your permission, state a few facts for the information of English farmers. I visited portions of Manitoba and the Canadian North West, as also of the adjoining States of Dakota and Minnesota, in the Union, the great Red River country, as well as a great extent of country south and east. My visit was necessarily a hurried one, but I saw many things that surprised and instructed me, and I wish our farmers could see them also. One of the things that astonished me first and most, was the absolutely universal use through every district, of the self-binding reaper. I think I do not exaggerate when I say that throughout that great continent such a man as a farmer who ties his wheat, barley, or oats by hand is unknown; at any rate, I never saw or could hear of one. In England I believe that nine out of ten of our farmers have never even seen a self-binder at work. Since my return I have asked several why they do not use them here, and I have been told—1. In these bad times a farmer cannot afford to spend £60 on a machine. 2. In America the country where wheat is grown is quite flat, and the farming is done on a very large scale, and is more suitable for self binders. In reply I would say, first, that the regular price now paid in the States for a self-binder is 160 dol., say £33 (although not equal, doubtless, to those of English make, and though the price in Canada is higher, owing to their system of protection, coupled with their comparative backwardness in manufactures). Moreover, seeing that reaping machines are pretty generally used here, the calculation should be, not of the total cost of a self-binder, but the difference between the cost of an ordinary reaper and a self-binder, a comparatively small sum. Secondly, in America a great deal of wheat-growing land is undoubtedly quite flat—for example, the magnificent Red River country; but a still larger area, termed Rolling Prairie, is extremely like an average English county, without any trees or hedges, and the self-binder is used there just as easily as anywhere else. Moreover, it is quite a mistake to suppose that in America the farms generally are on a large scale. The Canadian quarter section of 160 acres fairly represents the amount of land ordinarily taken up, and broken by degrees.

There are a few gigantic wheat farms both in Canada and the States, but they are almost as exceptional as the 300-acre field we hear about in Leicestershire. I asked a farmer

in Manitoba whom I saw threshing out his wheat, how long he had used self-binders. He said, "For about nine years!" I said I did not know they had been invented so long. He said, "Not the twine ones, but we used wire, and though it occasionally damaged the thresher it did not do much harm, and we could never have done without them." When the wheat, barley, or oats are ready for cutting, the regular thing is for the farmer to turn in with a team of horses and a self-binder, and do the whole work by himself with the exception of being followed by a man or boy, often his own son, to stand the sheaves up as they are thrown off, his labour bill being consequently almost nil. I would ask our farmers to compare their own outlay on this work with that of the man in America who is growing wheat against them. I think if they would follow the system they would save at least four shillings an acre, besides the risk of the grain spoiling on the ground in wet weather, if not tied immediately after cutting. In America the threshing machine travels round the country, just as in England. The fuel used is nothing but straw, and this is the only use the straw is to the farmer in that country. At nightfall, when the threshing is finished, the great heaps of straw, like rows of houses in size, are set alight, and the prairie is a wonderful sight as the train rushes along with fires lighting up the horizon all around. Here our farmers have an enormous advantage. Even in these times the value of the straw ought to more than pay rent, rates, and taxes, whereas in America (I speak of the great wheat-growing country in the West), beyond what is wanted to feed the threshing machine, the straw is merely an encumbrance.

When I was in the Red River country in September the farmers were receiving 55 cents a bushel, say 18s. a quarter, for their wheat delivered at the elevators, to which it had probably to be hauled on an average at least ten miles. Since then the price has fallen considerably, and they are doubtless not getting so much. I was informed on the most competent authority there, that the farmers, as a rule, are hopelessly impoverished and in debt, exceeding anything known in England. Moreover, they are wearing out even the grand soil of the country, and must either adopt mixed farming, cattle being almost unknown there at present, or move further back from the railways and take up fresh land, when, unless we are foolish enough in England, to find money for them to build new railways, which will never pay a cent to any but the people of the country, they will not long be able to send wheat here at present prices. My conclusion is that wheat will continue to be grown in England, and at a profit, too, if our farmers will only adopt the economies practised by their brethren over the water. They have the grand advantage of a market at their doors for eggs, poultry, vegetables, &c., not enjoyed by their competitors, and if we assume, as I think we may fairly do, that the straw will pay rent, rates, and taxes, they are getting 14s. a quarter at this moment more for their wheat—say £2 10s. an acre, calculating 30 bushels grown to the acre—to pay for manure, while such labour as is essential is to be obtained at certainly less than half the cost. It is to be recollected, too, that all that country is under snow and ice for about six months in the year—a terrible handicap for them in every way. I could write much more, but must not trespass on your space beyond saying I returned home doubly convinced of the gross folly of protection. With their wonderful soil, resources, and ingenuity, the farmers and manufacturers of America find it at least as hard to secure a margin of profit as in this country, and the complaints of depression in agriculture and trade are, if possible, louder and deeper than at home.

On this subject Messrs. James and Fredrick Howard of the Britannia Ironworks, Bedford, have addressed the following to the editor of the *Pall Mall Gazette*:—

"We have read with interest the communication in your columns from Lieutenant-Colonel Wheatley. With respect to his remarks upon the use of harvesting machinery in the United States, he is mistaken as to the universal adoption of the self-binder. There are an immense number of self-delivery reapers in use (machines which deliver the corn in sheaves unbound), and which are sold at about 160 dollars each, but your correspondent is utterly mistaken in his statement that self-binders are to be purchased in the States for that sum. The average price of a self-binder—that is, a machine which cuts and delivers sheaves bound with string—is 300 dollars. The two largest manufacturers of binders in the United States have depots in London; their prices are £60 or sixty guineas each, and they get rather higher prices in America for the same machines than they do in England. Lieutenant-Colonel Wheatley is very much mistaken in the following assertion:—'In England, I believe, nine out of every ten of our farmers have never even seen a self-binder at work.' We should say that nine out of ten have seen them at work, for self-binders have been introduced into almost every locality, and the reasons against their more general adoption are not those assigned by your correspondent; the fact is that until recently no self-binder has been produced capable of dealing with the heavier and more laid crops which have to be encountered in England. The English manufacturers have for years past been striving to overcome the difficulties in dealing with such crops; and that they have succeeded was proved at the trials which took place last harvest by the Royal Agricultural Society of England, when both the £100 and £50 prizes were carried off by two English machines. With respect to the future we agree with your correspondent that 'wheat will continue to be grown in England,' and from our knowledge of America, and our constant intercourse with agriculturists in that and other wheat-producing countries, we feel convinced that the present unremunerative prices will check production, and the inevitable result will be higher prices. Wheat in the Western States of America is already termed 'the poor man's crop,' by which is meant that those who depend upon it are kept poor. Those who can afford to raise cattle, leave wheat-growing to the poorer farmers."—*Pall Mall Gazette*.

PRINCIPAL WALLEY ON THE DISEASES OF STOCK.

In reference to the food supply of our domestic animals, do we not find that in many instances breeders of stock are utterly ignorant as to the physiological wants of the creatures upon which they are so largely dependent for their own well-being? I grant that very often the feeder is not to blame; he provides food such as he has been led to expect is suited to the purpose to which he applies it, but he does not consider the digestive or assimilative capabilities of the animals placed under his care, and in this way he often meets with serious and unexpected losses. And more than this the tendency has grown of late years of purchasing very large quantities of what we may call prepared foods, i.e., cakes and meals and other kinds of manufactured feeding stuffs. These are in themselves splendid materials for feeding purposes; but how often are they made the channels by which inferior stuffs are got rid of at superior prices, to the detriment more frequently of the buyer than the seller.

Every day is the attention of those who are engaged in the investigation of the etiology of disease more particularly directed to the truth of what I have stated. Cattle are found dying after having partaken of a feed of a particular kind of cheap meal or of cheap cake, and on examination these are found to be mixed with different kinds of deleterious matter, in a state of chemical change, or swarming with countless millions of bacteria. Surely it were better that farmers should devote their attention more largely to this subject than they have done, and not take everything they are told by interested parties as gospel. I do not wish, nor do I intend by these remarks to injure sellers of such material, for I am perfectly well aware that in very many cases they are totally ignorant of the fact that the wares they vend have anything of a deleterious nature about them, and that, figuratively speaking, 'there is death in the mess of pottage they have prepared.' But when such things are frequently brought to light, it behoves both sellers and buyers to be on their guard.

The last division of sanitation I wish to touch upon to-day is our 'food supply.' Gentlemen, I should have been pleased had I been in a position to say to you on this occasion that the representations which have been made, and the labour which has been spent, in our endeavours to put this matter on a more satisfactory footing than it has hitherto occupied, but I have still to say that it stands pretty much where it was when I last addressed you on this subject. Certainly one step in advance has been gained, inasmuch as probably one of the largest veterinary gatherings which ever met in this country (the meeting of the British National Veterinary Medical Association, held in Manchester in August) adopted certain resolutions, which I had the pleasure and privilege to propose, tending to place this subject in its proper position, and to authoritatively show to those who have legislation on such subject in their hands, the steps that ought to be taken for the protection of our poorer brethren from the evil effects of unwholesome and injurious food. As matters are now, vile traffickers in a vile traffic are privileged to carry on their disgusting, and often death-dealing trade with impunity, and to gloat over their ill-gotten gains to their hearts' content.

Of equal importance with the foregoing is the subject of 'humanity to animals,' and I will preface the remarks I have to make under this head by observing that the veterinary surgeon is no thing if he is not 'humanitarian.' His daily life, his hourly warfare is with suffering, and he would be a brute indeed if he did not yield to the softening influence exerted by the continual contemplation of pain, which he is oftentimes powerless to relieve, and if such suffering did not give him a more extended sympathy with the helpless brute creation.

There are certain kinds of interference with the conscience and freedom of action of professional men which must be strenuously opposed, and feeling, as I do, that much *unwarranted suffering* is caused to animals by the performance of *unnecessary operations*, I must nevertheless confess that it is painful and annoying to see men stand up in a public meeting as the defenders of the animal world, and impute sordid and mercenary motives to those whose whole life is, as a rule, one of self-abnegation. I refer here to the charges made against our profession in connection with the subject of docking, at the meeting in Manchester to which I have before referred. I could not help regretting at the time—I regret it equally now—that a feeling of antagonism should have been stirred up between a most useful and most benevolent society and our profession, by the ill-timed and ill-judged observations of those who were supposed to represent the views of the former; and I sincerely hope that it will never again be my lot to witness the repetition of such a painful scene.

It is not my intention to refer further to the matter of 'docking horses.' I have already expressed myself publicly on this subject; but I must take this opportunity of considering, though it may be briefly, another and equally important subject, viz., the 'overstocking of the udders of cows.'

This is a matter upon which one would think, there ought to be difference of opinion amongst professional men; and while I prepared to allow that every man has a right to his own opinion in all things, I must at the same time declare that I cannot understand how an educated veterinary surgeon, with a knowledge of physiology, and a knowledge of the laws which control and guide the faculty of sensation, can be found to defend such an

unwarrantable practice, and even to refer to nature herself for a warrant for such practices. But so it is, and very specious are the arguments used, as they always may be used, in defence of the cruelty. The question is, in the first place, asked in our professional journals, by one of the defenders of overstocking, 'What about nature? How do these animals get relief who are unfortunate enough to lose their offspring immediately they are born into the world? I admit that the question is a specious one, but I do not admit that nature's cruelties to animals in a state of nature are, in any sense of the word, a warrant for our cruelties to animals in a state of domestication. It is argued that nature relieves herself by the pressure of the milk upon distended teats leading to relaxation of their sphincters, and thus providing an outflow for the retained milk, and relief for the overcharged gland; but is this always the case? What percentage of animals would there be that would not gain relief in this way? Let the records of the daily practice of those who are engaged in the treatment of animals in town dairies give the answer. Why do we meet with so many cases of mammitis in this city? and to what is it attributable? Largely, I answer, to the absurd, injurious, and cruel system of overstocking, which is so frequently practised by the sellers. But, it may be rightly asked, has the buyer nothing to do with this? The answer is an affirmative one, for if buyers of overstocked animals were not forthcoming it would not be worth the while of sellers to practise the system. A second argument is made use of, to the effect that there is no pain in overstocking. Such an assertion to me savours of a melancholy ignorance of the structure and function of secretory glands in general. The udder is an organ of highly complex conformation provided extensively with sensory nerves, and of great vascularity. Its acini are so intimately connected with each other that it is almost impossible that relief should be gained in the usual way, i.e., by swelling, when it becomes the subject of active hyperæmia or of inflammation; consequently, whenever the outflow of milk is prevented, pressure is exerted upon the acini and upon the blood-vessels; tension follows, and, after this, pressure upon the terminal ends of the sensory nerves, with the natural result of acute suffering. This latter is shown by the stiff, straddling, and sore gait of the victims of man's cupidity; by the oftentimes quickened pulse, the heightened temperature, and the unwillingness to move, observed in such cases. Some years ago I was called upon to examine a flock of black-faced ewes, of whose number between 60 and 70 had been brutally mutilated by some unknown miscreant, by the removal, wholly or partially, of their teats; and as the wounds caused thereby became healed, the outflow of milk was effectually prevented, and at lambing time (the lambs not being able to draw off the milk) the poor animals were found wandering miserably and miserably about the field, careless of their offspring, refusing to feed, and grinding their teeth in a most heartrending fashion. Was there no pain here? and, if not, whence the suffering? But it may be said, Ah! here you had the outlet for the flow of milk hermetically sealed. Granted all this, and giving the benefit of the doubt, to as great an extent as is possible, to the distended udder with unsealed teats, I have no hesitation in asserting that, even when the milk flows naturally and freely away, even then, I say, pain is produced. Unfortunately, the poor cow cannot speak; but all females are not in that defenceless position, and can fortunately get indubitable evidence, by analogy of the great pain which is caused, even when the sphincters of the teats are relaxed, by allowing the mammary gland to become distended beyond its natural capacity, and we can even gain valuable confirmatory evidence on this point from the effects produced by the overdistension of distensible organs in our own bodies; and the heaviest punishment I would wish to see inflicted either upon overstockers or upon those who defend the practice would be that they should be placed in the position of the overstocked cow for a period of twenty-four or thirty-six hours.

Another remarkable piece of evidence in favour of overstocking, or rather in defence of the operation, is sought to be drawn from the natural process of drying of the udder when cows are turned off milking for the purpose of fattening. It is stated that the natural result of allowing the milk to accumulate in the udder is the suppression of its secretion by the pressure exerted on the gland cells. Doubtless this is so, but does it not occur to the mind of any one using such an argument that it has two edges, and the very fact of this suppression, following the accumulation of milk, is an argument of the strongest nature against the system of overstocking? and that in proportion as the glandular function is interfered with by overstocking will be the loss to the purchaser of such animals? Gentlemen, I have one hope, and that is, that no pupil of mine will ever be found defending in a Court of Justice an absolutely indefensible, and highly reprehensible practice; or, by defending it, indirectly encouraging the unscrupulous trader to resort to mechanical means (such as the insertion of rice into the teats or the application of elastic bands) of arresting the overflow of milk from the udders of the unfortunate victims of their cupidity.

In conclusion, I would urge upon you the necessity of using your best endeavours to make yourselves acquainted with all the bearings of medical and surgical pathology; of looking (not glancing) carefully into the nature of every diseased process which may come under observation, and of investigating for yourselves every case and every specimen of an interesting nature that may be brought to your notice, either here or elsewhere. Depend upon it, that your future success in life will be in exact proportion to the use you make of your student days, of the faculties with which nature or nature's God has endued you, and that in proportion will these faculties fail if you allow the rust of indolence to accumulate about them, and the friction of indolence to wear them premature away.—*North British Agriculturist.*

A SKILFUL SURGICAL OPERATION.

THE American Ambassador at Vienna, Mr. Kasson, has lately forwarded to his Government an interesting account of a remarkable surgical operation lately performed by Professor Billroth, of Vienna, which, wonderful to tell, consisted in the removal of a portion of the human stomach, involving nearly one-third of the organ—and, strange to say, the patient recovered—the only successful operation of the kind ever performed. The disease for which this operation was performed was cancer of the stomach, attended with the following symptoms:—The appetite is quite poor. There is a peculiar indescribable distress in the stomach, a feeling that has been described as a faint "all gone" sensation; a sticky slime collects about the teeth, especially in the morning, accompanied by an unpleasant taste. Food fails to satisfy this peculiar faint sensation; but, on the contrary, it appears to aggravate the feeling. The eyes are sunken, tinged with yellow; the hands and feet become cold and sticky—a cold perspiration. The sufferers feel tired all the time, and sleep does not seem to give rest. After a time the patient becomes nervous and irritable, gloomy, his mind filled with evil forebodings. When rising suddenly from a recumbent position there is a dizziness, a whistling sensation, and he is obliged to grasp something firm to keep from falling. The bowels costive, the skin dry and hot at times; the blood becoming thick and stagnant, and does not circulate properly. After a time the patient spits up food soon after eating, sometimes in a sour and fermented condition, sometimes sweetish to the taste. Often-times there is a palpitation of the heart, and the patient fears he may have heart disease. Towards the last the patient is unable to retain any food whatever, as the opening in the intestines becomes closed, or nearly so. Although this disease is indeed alarming, sufferers with the above-named symptoms should not feel nervous, for nine hundred and ninety-nine cases out of a thousand have no cancer, but simply dyspepsia, a disease easily removed if treated in a proper manner. The safest and best remedy for the disease is Seigel's Curative Syrup, a vegetable preparation sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White (Limited), 17, Farringdon-road, London, E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

ST. MARY-STREET, PETERBOROUGH.

November 29th, 1881.

Sir,—It gives me great pleasure to inform you of the benefit I have received from Seigel's Syrup. I have been troubled for years with dyspepsia; but after a few doses of the Syrup, I found relief, and after taking two bottles of it I feel quite cured.

I am, Sir, yours truly,

MR. A. J. WHITE.

WILLIAM BRENT.

September 8th, 1883.

"Dear Sir,—I find the sale of Seigel's Syrup steadily increasing. All who have tried it speak very highly of its medicinal virtues; one customer described it as a "God-send to dyspeptic people." I always recommend it with confidence.—Faithfully yours,

(Sd.) VINCENT A. WILKS,

Chemist-Dentist, Merthyr Tydvil.

TO MR. A. J. WHITE.

Seigel's Operating Pills are the best family physic that has ever been discovered. They cleanse the bowels from all irritating substances, and leave them in a healthy condition. They cure costiveness.

Preston, Sept. 21st, 1883.

My dear Sir,—Your Syrup and Pills are still very popular with my customers, many saying they are the best family medicines possible.

The other day a customer came for two bottles of Syrup and said "Mother Seigel" had saved the life of his wife, and he added, "one of these bottles I am sending fifteen miles away to a friend who is very ill. I have much faith in it."

The sale keeps up wonderfully, in fact, one would fancy almost that the people were beginning to breakfast, dine, and sup on Mother Seigel's Syrup, the demand is so constant and the satisfaction so great.

I am, dear Sir, yours faithfully,

(Signed) W. BOWKER.

TO A. J. WHITE, ESQ.

Spanish Town, Jamaica, West Indies, October 24, 1882.

Dear Sir,—I write to inform you that I have derived great benefit from "Seigel's Syrup." For some years I have suffered from a liver complaint, with its many and varied concomitant evils, so that my life was a perpetual misery. Twelve months ago I was induced to try Seigel's Syrup, and although rather sceptical, having tried so many reputed infallible remedies, I determined to give it at least a fair trial. In two or three days I felt considerably better, and now at the end of twelve months, having continued taking it, I am glad to say that I am a different being altogether. "It is said of certain persons that they 'come as a boon and a blessing to men,'" and I have no reason to doubt the truthfulness

of the statement. I can truly say, however, that Seigel's Syrup has come as a "boon and a blessing" to me. I have recommended it to several fellow-sufferers from this distressing complaint, and their testimony is quite in accordance with my own. Gratitude for the benefit I have derived from the excellent preparation, prompts me to furnish you with this unsolicited testimonial.

I am, dear Sir,

Yours ever gratefully,

(Signed) CAREY B. BERRY,

Baptist Missionary.

A. J. WHITE, Esq.

Hensingham, Whitehaven, October 16, 1882.

MR. A. J. WHITE.—Dear Sir,—I was for some time afflicted with piles, and was advised to give Mother Seigel's Syrup a trial, which I did. I am now happy to state that it has restored me to complete health.—I remain, yours respectfully,

(C)

(Signed) JOHN H. LIGHTFOOT.

AT ALL CHEMISTS' AND DRUGGISTS'.
Beware of Spurious Imitations

GRIMAULT & CO.,

PHARMACEUTICAL CHEMISTS,

Paris : 8 RUE VIVienne, 8 : Paris.

DISEASES OF THE CHEST.

GRIMAULT & CO'S SYRUP OF HYPOPHOSPHITE OF LIME.

PERSONS suffering from CATARRH, CONSUMPTION, COLDS, or OBSTINATE COUGH, and generally those afflicted with diseases of the chest, bronchia, or lungs, should use GRIMAULT & CO'S SYRUP OF HYPOPHOSPHITE OF LIME, which, prescribed for years past by the medical authorities of all countries, has invariably effected wonderful cures.

By the use of this Syrup the Cough is calmed, nocturnal sweats disappear, and the appetite rapidly improves—a fact soon demonstrated by an increase of weight and improved appearance.

GRIMAULT'S SYRUP is of a rose colour, and contained in flat oval bottles.

GRIMAULT & CO'S MATICO CAPSULES & INJECTION.

Renowned Physicians prescribe GRIMAULT'S MATICO as the most active, and at the same time the most inoffensive remedy in the treatment of ACUTE and CHRONIC DISEASES. These Capsules have not, like COPAIBA, the inconvenience of giving NAUSEAS. The Injection is used in recent, and the Capsules in the more chronic cases.

DUSART'S SYRUP OF LACTOPHOSPHATE OF LIME.

This preparation enriches the blood, strengthens the bones, and improves all the vital energies.

Phosphate of Lime is the substance most necessary to life; indispensable for the formation and nutriment of the bony system, as for the transformation of food into muscular fibre. Without it, the body wastes away, and it is to supply the lack of Phosphate of Lime that Dusart's Syrup is so useful. It is of inestimable benefit for CONVALESCENTS, WEAK and OLD PEOPLE, and RICKETY CHILDREN, who find in it the CALCAREOUS ELEMENTS entering into the CONSTITUTION OF THE BONES. Well adapted to LADIES in the FAMILY-WAY, WET NURSES (whose milk it enriches), and to stop CHILDREN'S DIARRHŒA.

ASTHMA! ASTHMA!

GRIMAULT & CO'S INDIAN CIGARETTES.

ASTHMA, NERVOUS COUGHS, CHRONIC LARYNGITIS, HOARSENESS, LOSS OF VOICE, FACIAL NEURALGIA, AND INSOMNIA, are rapidly relieved by using these Cigarettes.

SICK HEADACHE! NEURALGIA!

GRIMAULT & CO'S GUARANA.

This Medicine owes its curative virtues to the great quantity of Caffein which it contains. Dr. Wilkes, of Guy's Hospital, declares in the *British Medical Journal* that GRIMAULT'S GUARANA acts "like a charm."

"Grimault's Guarana Powders are a certain remedy for Sick HEADACHE."—*The Lancet*, Aug. 31, 1872.

It is the most valuable remedy against DIARRHŒA, DYSENTERY, and all disorders proceeding from derangements of the Stomach and Bowels.

Agents—BATHGATE & Co., SMITH, STANISTREET & Co., BONNELL & Co., and NOBIS CHUNDER DAW & SONS, Calcutta; TREACHER & Co., Bombay; BARRIE & Co., MADON & Co., and NORTON & Co., Madras; FLOMER & Co., Lahore; PRAKE, ALLEN & Co., Lucknow; BRADS & Co., Bangalore; and at all respectable Chemists.

CALCUTTA:—SATURDAY, JANUARY 10, 1885.

[No. 2.]

Crop and Weather Report.

[FOR THE WEEK ENDING THE 31ST DECEMBER, 1884.]

General Remarks.—Rain has fallen in all districts of the Madras Presidency, but nowhere so heavily as during the week preceding that under report. No report has been received from Mysore, and in Coorg there has been little or no rain. Rain has fallen throughout the Deccan and Southern Mahratta Country and parts of Guzerat and the Konkan, where it was needed most, but more rain is still required in part of some districts. Rain in varying quantities has fallen throughout the Central India States and at some places in Rajpootana. In the Berars there has been good rain, and the weather continues cloudy. No report has been received from Hyderabad. Slight rain has fallen generally throughout the North-Western Provinces and Oudh, and the weather continues seasonable. Except at Lahore and Unrisur, no rain has fallen in the Punjab. In the Central Provinces there have been occasional showers which have proved beneficial to the crops. In Bengal a little rain has fallen in more than half-a-dozen districts.

There is little or no change to record in agricultural operations. Harvesting continues in Madras and standing crops are generally in good condition, except in Bellary and Kurnool where they are in want of more rain, and in Tanjore where they have been damaged by excessive rain and floods.

In Bombay *rabi* prospects have been improved by the recent rain, and in the Central Provinces, the North-Western Provinces and Oudh, and Punjab the condition of the crops is generally very good. The *rabi* crops are also promising in Bengal, where the *aman* paddy is still being harvested, the outturn being fair in some districts. In British Barmah the rice harvest has been completed in some and is well advanced in other districts; the outturn has been satisfactory. The public health is generally good. In Tanjore and Madura the mortality from cholera is still heavy.

Prices are fluctuating in Bengal and the Punjab, but elsewhere generally stationary.

Madras.—General prospects fair; rain in parts of Bellary; prospects not improved in Anantapore.

Bombay.—Rain throughout the Deccan and Southern Mahratta Country and parts of Guzerat and the Konkan; standing crops much benefited in parts of Poona, Ahmednugger, Sholapore, Dharwar, Belgaum, and Kaladgi, but slightly injured in parts of Nasik, Khandesh, Kaira, and Thana; more rain still required in parts of some districts; crops injured by hail in one taluka of Dharwar and 2 of Kaladgi; cholera, cattle-disease, and smallpox in parts of 7 and fever in parts of 13 districts.

Bengal.—Some rain fell in more than half-a-dozen districts; *aman* paddy is still being harvested, and a fair outturn is expected in some districts; *rabi* crops are coming on well, but a little rain would do good; price of rice has fallen in some districts and in others it is stationary; sugarcane-cutting continues; sporadic cases of cholera still continue to be reported from many districts, while fever still prevails in some.

N.-W. Provinces and Oudh.—Weather seasonable with a slight sprinkling of rain here and here; *rabi* crops flourishing; opium promising; and excepting a little sickness in Kumaon, public health is good.

Punjab.—Fever decreasing in the Hissar and Umballa districts, but the health of the rest of the province is generally good; *rabi* sowings completed; prospects on the whole good; prices fluctuating.

Central Provinces.—The weather has continued cloudy with occasional showers which are beneficial to *rabi*; health good; prices steady.

British Barmah.—Except sporadic and trifling cholera and small-pox, public health of province good; harvest over in some districts and well advanced elsewhere, and outturn satisfactory.

Assam.—State and prospects of crops good; cholera and small-pox here and there. Weather rainy; *sali dhan* being reaped; public health good.

Mysore and Coorg.—Standing crops generally in good condition; more rain required, especially in Tumkoor district; prospects favourable; public health good.

Berar and Hyderabad.—Weather cloudy and rainy; *jowari* and cotton crops somewhat damaged.

Central India States.—Health and prospects good; opium sowing finished; prices falling slightly.

Rajpootana.—Crop prospects favourable; prices steady; health good.

Nepal (Dec. 25).—Weather fair; prospects good.

Editorial Notes.

THE *Ceylon Times* is glad to see that amongst the new ordinances shortly to be laid before Council, is one for extending the provisions of the Coffee-Stealing ordinance to other and newer products. It hopes it may be comprehensive, and include all new products and the plants thereof. A Forest ordinance also is about to be brought forward. Considering the rapid way in which ordinances are rushed through Council, often before the general public are thoroughly acquainted with their provisions, our contemporary suggests that the draft of both those important measures should be published at once, so that those interested may have an opportunity of discussing various provisions contained therein.

.

THE *Home News*, alluding to gold mines, says:—The business has this week been largely confined to Indian gold mines, and considerable transactions have taken place in the shares of the Mysore, Nundydroog and Ooregum Companies. Curiously enough, however, Indian shares have been weaker since the receipt of the last telegram from Captain Plummer, of the Mysore Company, which was the most favourable on record, announcing, as it did, a crushing with a yield of three ounces of gold to the ton. There are in the air rumours of reconstructions of defunct companies in the Mysore field, and a meeting has been held of the Dingley Pell Estates Company—a concern in the Wynnad district, but which has also 320 acres in the Mysore district. It is proposed to sell a portion of the latter estate for £10,000, retaining 120 acres. A meeting was also held of the Nundydroog Company, at which the subject of reconstruction was considered. The capital of the new Mysore Gold Mining Company (Limited) is £100,000, in £1 shares to be issued at a discount of 15s. per share. A circular accompanying the prospectus says: "It is proposed to continue sinking the shaft (now 103 feet deep) to the depth attained by the neighbouring Mysore mine, when the same rich deposits are expected to be met with, as the report states that this portion of the Mysore block contains the same reefs, and the first crushing of which mine are as follows—1884—June, 101 tons—result, 52 ounces; July, 85 tons—result, 88 ounces; August, 95 tons—result, 96 ounces; September, 126 tons—result, 128 ounces; October, 94 tons—result, 180 ounces; November, 12 tons—result, 363 ounces.

.

An interesting correspondence has been published by the Government of Madras on the subject of the crude Cinchona bark. It appears that some suggestion put forward in the Administration Report to Government by Mr. M. A. Lawson, Director of Government Cinchona plantations, Botanical Garden and Parks, Nilgiri, has attracted the attention of the Surgeon-General in that Presidency, who remarks "that the use of the crude bark is very wasteful and expensive owing to the fact that infusions and decoctions soon ferment in this country."

Mr. Lawson holds that such a mode of administering the febrifuge might certainly be adopted, but the infusion or decoction would of course have to be made at the time it was required for use; just as in England an infusion of senna is now made by the poorer classes. But even if this was done, there would still result a considerable waste, inasmuch as a portion only of the cinchona alkaloids is removed by either of these processes. If, however, instead of the bark being infused or boiled it was to be steeped in some weak spirit, such as arrack, the loss of alkaloids would be extremely trifling, for a weak spirit dissolves out nearly the whole. If then a powder of a fairly constant value was made (and this could be easily done), there is no reason why it should not be sold in every country village, and the natives be allowed to obtain, either by instructions or by experiment, the amount of powder necessary for a dose. With respect to the suggestion of the Surgeon-General that the Government Quinologist should give his attention to the preparation of a fluid extract of cinchona, it is said that this is already being done by Mr. Hooper. This preparation contains a definite amount of the cinchona alkaloids in every ounce of the fluid, say 24 grains to the ounce. This preparation, or any other, which the medical profession may determine to be the most convenient, can always be maintained without difficulty. Mr. Hooper's extract, Mr. Lawson adds, is not more unpalatable than the sulphate of quinine itself, and it possesses moreover this advantage, *viz.*, that it may be diluted to any extent with water. The keeping properties of the extract will probably be great, but this is a matter which must be tested by experiment. The manufacture of the extract would be inconceivably economical, and could be carried on equally well on the Nilgiris or in Madras.

.

VERY few of our readers are aware that there are large tracts of land in the Assam Valley which are classed as "precarious" or "insecure." These tracts are the alluvial or *chapari* mauzabs which extend along both banks of the Brahmaputra, but are also found to cover a large area in the districts of Kamroop and Nowgong. Cultivation is very precarious here owing to their liability to untimely inundation by the great river, or by the numerous creeks and channels which its affluents intersect the country in all directions. The crops they yield are broadcast summer rice (*ahu*) and Indian mustard; the former is harvested in July and August, and the latter is sown in October and November; if therefore the rainy season opens with, and is succeeded by, high floods, double misfortune awaits the cultivators; the rice crop may be lost, and the ploughing for the mustard may be deferred till the season is far advanced. The food crop is the more precarious of the two, but the other is perhaps of greater importance to the cultivator. These lands are not, as a rule, retained longer than three years, after which period the cultivators move their temporary homes to fresh clearings in the reed jungle with which their *chapari* tracts are densely covered. The system of annual settlements is well adapted to fluctuating cultivation of this kind. The mandal prepares his papers on the basis of the area actually cultivated year by year, and the assessment of eight annas a *big'a* represents the share of the Government in the produce raised by the cultivator in that year. If the crop be lost or destroyed there is no remission granted. This at first sight appears to press heavily on the cultivator, but the facts are that total loss in a large area is rare; that remissions have never been known by them, and to allow them such remissions, would be tantamount to involving complications in a revenue system which works well, because it is extremely simple.

.

BUT some material concessions have been made in favour of the cultivators in the collection of revenue in these *chapari* mauzabs. There has been a general wish on the part both of the ryots and the mauzadars that instead of the two revenue *kists* (15th October and 15th November) there should be a single *kist* in March or April, so as to allow the ryot to gather in his mustard crop before being called in for payment. Under the Assam Settlement Rules, according to Mr. Stack, the October *kist* of three-fifths is levied on all lands which fall into the main settlement, the remaining two-fifths being paid in the January *kist*, which in the case of *daryabadi* lands, *i.e.*, lands which

come into cultivation for the first time in October and November, the whole assessment is taken in the single *kist* of January. To meet these demands on account of mustard lands, the ryot takes an advance from the dealer to whom he sells his crop, repaying the crop at harvest time with interest at 90 per cent per annum! It must not, however, be supposed that this undesirable state of things owes its origin to the Government demand; besides, it is doubtful whether any change in the *kist* dates would obviate the necessity of rushing into the arms of the money-lender. Yet the Government think it incumbent to adjust the times of payment of their demands as nearly as possible to the convenience of the cultivator. It has therefore been ruled that in *chapari* mauzabs (mauzabs having one-sixth at least of the cultivated area under mustard,) the revenue demand is to be collected in a single instalment on the 15th February, which would not necessitate his borrowing at all; but if he did, it will be for a much shorter time, and he will have to pay one or two months' interest, instead of six or seven as heretofore.

.

FROM the returns of the rail-borne trade of the Berars, it appears that the total imports during the quarter ending the 30th September amounted to 332,041 maunds and the exports to 241,950 maunds. The trade, which is mainly with Bombay and the Central Provinces, showed the usual falling off for this period of the year,—a falling off chiefly due to the occurrence of the rains. The decrease amounted to 367,122 maunds, or 52.5 per cent in the imports; and 996,552 maunds, or 80.4 per cent in the exports. Nearly half of the decrease in imports was due to the salt trade, which fell from 191,232 maunds to 11,056 maunds. In exports the decrease was principally under cotton raw (282,816 maunds), wheat (217,681 maunds), and linseed (465,681 maunds). In spite of this decrease, the trade of Berar shows a considerable advance on previous years.

.

THE following is abbreviated from an article by Herr Em. von Proskowetz, jun., in the *Wiener Landwirtschaft Zeitung*, quoted in the Berlin *Deutsche Zucker Industrie*:—About two years ago a very experienced German cattle-dealer drew my attention to feeding stock with molasses, assuring me that the flesh of cattle thus fed was particularly well flavoured, and the fat firm. My first attempt was a small one, but last year I tried the system on a larger scale, and as I had every reason to feel satisfied with the result, I think it my duty to give information on the subject. This year I intend to feed all my stock in a similar way, although probably to an increased extent. Last year, of 110 oxen, treated under identical conditions otherwise, the 60 which were fed with molasses increased in weight on the average 7½ oz. a day more than the 50 to which molasses was not given. A most important point in feeding with molasses is the manner in which the food is prepared. As far as I could ascertain, the molasses has usually been more or less thinned with water, even to the extent of giving the animals the mixture to drink. I feel, however, confident that, at all events where the stock consumes much beet refuse and the like, this thinning process has been the cause of many failures in successfully feeding with molasses, owing to the laxative effect. Acidification, especially in wooden mangers, easily sets in; and the same quantity of sugar dissolved and undissolved will act very different. According to my observation, which I admit only extends over a short period, the molasses is best when not thinned; indeed, the greater the concentration the better. It should be mixed as thoroughly as possible with the food, and the cattle take it readily, leaving none. Cleanliness is very important. It is better not to give the cattle salt, when fed with (beet) molasses, and water should be sparingly administered."

.

THE *Horn and Colonial Mail* says: "Our Commissioner in the Lane draws attention in his weekly report to an expression of dissatisfaction in the sales this week at the number of small breaks. We have also received a complaint from a correspondent on the same subject, and we cannot help expressing our opinion that, from a buyer's point of view, it would be desirable to have an alteration. But there are two sides to every question,

so it must not be over-looked that a selling broker has to carry out the instructions of the importer, and if an invoice of tea be given him to sell, which includes a few single packages of Pekoe Dust or Fannings, which the planter has packed off out of the way, there is no alternative but to print them, and get the best possible price for them. We can see, however, by the tone of our correspondent's letter that more or less irritation is caused by small breaks being offered in the large sales, and it would be well if the selling brokers could see their way to meet the wishes of the buyers by withdrawing all non-sampling breaks, and selling them at their own sale-rooms afterwards. A much more satisfactory way out of the difficulty would be for planters to hold back all lots of less than twelve chests, and include them in a subsequent shipment bulked in with the tea of the same grade. We have always tried to hold the balance fairly between buyers and sellers, and we have never ceased to regard their interests as identical, if they could only see it for themselves. We believe that this trifling matter may quite easily be arranged if there be the desire on both sides to avoid friction. It is neither dignified nor business-like that such disturbances should be continually taking place in the Indian Tea sale-room. The buyers have certainly some grounds for complaining, seeing that the precious daylight so soon goes now in the afternoon, and it cannot fail to irritate those who are heavy operators, if they are obliged to 'sit like Patience on a monument' when they might be usefully employed elsewhere in extending the franchise of Indian tea, or promoting redistribution to the remotest village in the land."

**

With the following notes, we conclude the article on 'Sugar Bounties' from the *Fortnightly Review*:—In this matter of sugar bounties alone, no English taxpayer would for a moment hold his peace. He would bluntly say, "Either this making of sugar from beet pays, or it does not. If it does, I am not going to contribute to the profits of the manufacturers; if it does not, I refuse to make them good their losses." But the foreign taxpayer holds his peace; and, whether it be in ignorance or in fear, it exhibits an equally lamentable absence of the primary conditions of individual freedom. And the evil lies deeper than is ordinarily acknowledged. Assume that the sum obtained in bounties exceeds £2,000,000 in the year; this means that the manufacturer has paid in sugar duties £4,000,000, and when he exports the sugar he receives £6,000,000. Thus, in addition to the £2,000,000 extra for bounties, the taxpayer has also to provide other revenue to the amount of £4,000,000 to make good the withdrawal of that amount from the yield of the sugar duties. In addition to this, there is the drawback which has to be provided and paid on sugar which by various processes, even of direct fraud, has never paid any duty at all. The system thus costs the continental taxpayer over £6,000,000 direct charge in the year, or the equivalent, even according to the English yield, of something like 1d. in the pound of income-tax.

*

BOUNTIES, being only obtained on exports and with the aid of high import duties, by one and the same stroke drive out of the country all sugars produced in it, and also curtail supplies from abroad. One consequence is that the consumer has to pay more in these bounty-giving countries for even his own "national" sugar than is paid for it by the foreigner. The Parisian, for instance, is now actually paying 8d. for French sugar which the "perfidious Londoner" is only paying 3d. for. Another consequence is, that the consumer obtains a worse article. English refiners know well that their weakest and worst sugars go to the highly "protected" countries; and just now in Marseilles and Nantes, the weakest and worst of English refined sugars are being retailed at high prices, because by reason of their very badness they can enter at the lowest rates of duty. The *reductio ad absurdum* is attained in the new French law, under which it appears possible for an English merchant to buy Paris-made sugar in the low-priced English market, and send it back to Paris and sell it there at considerable profit. Consumers in most continental nations, wildly and without the slightest protest, pay twice as much as they need for all their sugar; and in addition, and in order to

keep going the system that compels these prices, they contribute a revenue sufficient of itself to pay for some "glorious little war." Some authorities in our own manufacturing districts have pointed out that our general exports to certain bounty-giving countries show a significant falling off as sugar bounties increase. This is further evidence of the fact that bounties impoverish the countries that allow them, as they are so much out of the pockets of the people which might otherwise have been invested in profitable exchange or production. The one result they can boast is that an industry is thus kept alive which could either live by itself, or else is a dead loss to the community as a whole. But this plain truth is allowed to pass unheeded, because the losses are distributed over the whole community, whereas the profits are concentrated on a few individuals. What is seen is small, but all profit; what is not seen is enormous, and all loss. Would there was another Bastiat to show this to those whom it concerns! Experience teaches us hardly to expect it in a republic, but in a monarchy we might hope some native Cobden would arise in defence of the many against the few—in defence of the national prosperity against that which a small class of individuals "surreptitiously abstract from the pockets of too-confiding fellow-countrymen."

**

BUT the day seems not far distant when these scales will fall from the eyes of foreign nations, more especially as their treasuries come to feel the pressure of the system, and can thus influence the Governments to appreciate the consumer's losses. In each beet-growing country in turn, in Austria, Holland, France, and Belgium—it comes to be found that under this strange system, the greater the output of sugar the less the net yield of sugar taxes. And now Germany is feeling the pinch. In 1882 the net sugar revenue was £2,300,000; in 1883, the output was 20 per cent larger and the nett yield 30 per cent less, being only, £1,500,000. Progress on this ratio will in two years result in actual deficit. All this bouleversement of these important industries is wrong and unprofitable; the evils incidental to the system, if reduced to a money standard, clearly and materially outweigh any advantages from the strictly English no less than from the international point of view. Even in these vaunted low prices, the difference is none the less made up by the consumers to the producers, although it is, in taxes, and not in trade payments.

**

WE may now give a fuller definition of the evil that lurks inherent in the bounty system; we find it to be, as it were, hydra-headed.

The bounty system—

I. Is an artificial interference with the industry of sugar-making, hampering production, exchange, and consumption.

II. Has caused gratuitous over-production and glut, leading to a ruinous fall in prices.

III. Is forcing many people to use that sugar which it costs much to produce to the exclusion of that which it costs least to produce.

IV. Enables growers of expensive sugar to hold their own against growers of less expensive sugar.

V. Causes a dead loss to aggregate national wealth, and thus arrests general progress.

VI. Severely strains international comity, and checks the advance of free exchange among nations.

VII. Impoverishes those nations which allow it—

(a) By raising the price of refined sugar to the local consumer.

(b) By raising the price of raw sugar to the native manufacturer, and lowering the price to his foreign competitor.

(c) By forcing the taxpayer to contribute millions sterling a year to make up the losses or at best increase the profits of a small class.

(d) By forcing the taxpayer to make up by other sacrifices the deficit caused in the revenue derived from sugar.

(e) By supporting at the public expense an industry which is either unprofitable or could stand by itself.

I would conclude by a brief statement of a remedy which shall be at once practicable, desirable, and effectual. The Select Committee of the House of Commons in its report declared distinctly that "they felt themselves precluded from recommending" a countervailing duty, but that "the most effectual mode of stopping bounties is manufacturing and refining under excise supervision;" and that this could be put in practice by summoning a Conference of the sugar-producing Powers. Manufacture under excise supervision means that no sugar will be consumed on which duty has not been paid, either on

issuing from the factory or on import. No bounties are possible under this system, as was proved when it was tried in England. This, then, is the remedy, and that it should be political rather than economical is a natural consequence to the fact that the evil is political in origin, although economical in effect.

FINALLY, as to the measure necessary to its application. The Governments of European countries are, and have long been, desirous of putting an end to the bounty system, and there have been several Conferences held with that end in view. They have discussed and condemned various palliatives, and on separating from the last Conference in 1877, they had so far come to a general conclusion that manufacture under excise supervision was a good and complete remedy. The hitch lay in obtaining a general assent to the institution of the system. Would all the countries bind themselves in solemn convention to the one system? That is a question which has not yet been answered, and which can be answered at a new Conference. All the countries concerned have endeavoured, within their own borders, to put an end to the system. Austria did so by establishing a minimum of contributions to the revenue from the sugar duties, drawbacks (and so, bounties) only being allowed after that minimum had been paid in. Belgium has followed suit. France some time ago halved the sugar duties, which incidentally halved the bounties, and made them intrinsically little more than nominal. Germany recently determined thus to follow in the wake of France. But there was no security that these arrangements would last; there was no common compelling power; and France, as if to prove the justice of these fears, has suddenly gone off at a tangent, and in alleged protest against the heavy German bounties, has again established a system of bounties larger than those obtained in Germany. In this war of bounties all must lose.

I HAVE on a previous page summarised several of the evils the system brings on foreign nations. If this list, supplemented as it easily might be from local experiences, was taken to heart by the taxpayers of France and Germany and the other beet-growing countries, there might be some possibility of awakening the individual from his suicidal torpor, and at once forcing and enabling the Governments of those countries to meet together in a new Conference, and sign a common convention to "manufacture under excise supervision." One word remains as to a common compelling power, and the crucial question as to how recalcitrant States are to be dealt with. In the first place all the States may agree to sign; and this can only be discovered on the actual assembling of a new Conference. But although there is good reason to hope for this, nevertheless it is conceivable that some one or other Government may not see its way to signing some particular convention. Against such recalcitrant States two penal clauses have been suggested for insertion in any convention. These are, a countervailing import duty to be placed on all imported sugars that have received a bounty; and the other, absolute prohibition of all imports of sugar from countries where bounties are allowed. It is held that neither of these clauses could be or would be accepted by England. I ask, need they be even so much as proposed at a Conference?

THE Conference is called to put an end to the bounty system. The convention it could adopt might contain three simple clauses to the following purport:—The signatories bind themselves individually not to allow bounties to be obtained on sugar within their frontiers, and they will make it penal to obtain drawbacks even one farthing in excess of what has been paid in duties. The signatories declare bounties on export to be contrary to the most-favoured-nation treatment; and that any article obtaining a bounty on export is, *ipso facto*, excluded from the most-favoured-nation treatment in all existing treaties. The signatories bind themselves, whenever they wish to raise revenue from sugar, only to allow manufacture or refining under excise supervision. The first and third of these clauses need no comment; the second may be termed a codification of a point in international law, and it will be observed it leaves

the signatories perfectly free in their particular method of action in regard to recalcitrant Powers, but it places those Powers entirely at the mercy of the signatories. I venture to suggest that by such a convention the evils I have defined as inherent in the bounty system would be once and for all arrested, and England and the Continental Powers equally relieved of an industrial incubus that is sucking the life-blood of profit out of all undertakings—agricultural, manufacturing, or commercial—that have any connection with sugar.

THE following notes by Mr. E Stack on silk in Assam will be read with great interest:—Some misapprehension seems to prevail among English silk-spinners with regard to the nature of the silkworms which furnish the silks of Assam. I find the domesticated *muga* and *eri* included in Mr. Wardle's pamphlet on the wild silks of India, while in a lecture on silk-spinning delivered in the Technical College, Glasgow, the tussar worm is alluded to as generally cultivated in this province. A similar misconception (so far as Assam is concerned) appears to pervade the Resolutions of the Government of India of the 23rd November 1875 and of the 28th February 1879, directing attention to undomesticated silk-spinning worms in general and to the tussar silkworm in particular, and asking for certain information regarding them. The information required will be found in the second part of this Note; but in treating of the silks of Assam it is desirable to make it clear at the outset that from the wild silkworms of Assam, as they now exist, nothing whatever is to be expected. They may possess a scientific interest, but they are certainly destitute of all commercial value, present or prospective. Their cocoons in the wild state are not to be found in numbers anything like sufficient to repay the cost of collecting, or to furnish the slightest hope that they will ever be able to supply the English market. It is exceedingly doubtful whether by the most strenuous efforts one hundredweight of wild cocoons of all sorts could be collected in the whole of the Assam Valley. The commonest of all is the variety of tussar called *kukhuri* in Assam, and this is so rare that virtually one never hears of it. In times previous to British rule, this worm used to be cultivated to a small extent in the vicinity of Jorehat, but it has long fallen out of fashion, and in 1877 the Chief Commissioner of Assam (Colonel Keatinge) was of opinion that to attempt to create a tussar silk industry in this province would be simply to court failure. More recently the failure of Major Cousmaker's operations in the Deccan has proved the futility of attempting to make anything out of tussar in Assam, where it is vastly less abundant. Such being the prospects of tussar, it is hardly necessary to speak of the other wild worms of Assam. Eight species are described hereafter, whereof three are the wild varieties of the *pat*, *muga* and *eri* worms, and none of them are turned to any practical account, though cocoons found by chance in the jungle may occasionally be brought home by the cultivator and reeled or spun together with cocoons of his own brood. In the wild state they occur but sparingly, their principal habitat being the dense and unpeopled jungle of the submontane tracts, while the possibility of domesticating them in Assam need not be considered for a moment. It is not to be expected that the Assamese, who take so little care and trouble with the domesticated worms they have already, could ever be induced to make experiments with a new species, nor is there any reason to believe that the produce of the wild worms, even if successfully cultivated, would prove in any way superior to the existing silks of the country.

DISMISSING the wild worms, therefore, from consideration altogether, we have three kinds of domesticated worms in Assam, or rather, it may be said, in the Brahmaputra Valley, for the Surma Valley is not generally a country of silk cultivation. These are the *pat* or mulberry worm (*bombyx textor*); the *muga* or sun-felling worm (*anthracis assama*) whose cocoon, like that of the *pat*, can be reeled; and the castor-oil worm (*attacus ricini*) yielding a silk which is never reeled, but spun by hand. Looking simply to their commercial potentialities, these three species of silkworm may at once be reduced to two, by striking out the mulberry worm (*pat*) on account alike

of the costliness of its silk, the scantiness of the present supply, and the difficulty of extending its cultivation. The two remaining species, the *muga* and *eri*, present a much more hopeful field of enterprise. They are produced in considerable quantity already, they are thoroughly adapted to the climatic conditions of Assam (being, indeed, probably indigenous to this part of India), and there is no obvious reason why their cultivation should not be capable of immense development. The *eri* is the more promising of the two, both because it is cheaper and more abundant, and also because, being reared entirely indoors, its cultivation does not entail that troublesome necessity of watching by night and day, which is imposed upon the *muga* breeder during the period that his worms are on the trees. The *muga*, indeed, yields the finer silk, but as it is only in the roughest shape that Assam silk can hope to become an article of demand in the English market, the difference of quality will, perhaps, prove to be a matter of secondary importance.

.

THERE are two forms in which a silk trade is conceivable between Assam and England. We may export the thread, or we may export the cocoons. It may be said at once that the export of thread would never pay. *Muga* thread is now selling at about Rs. 8 and *eri* at about Rs. 5 the seer (6s. 8d. and 4s. 2d. the lb.); and when it is remembered that the reeling is of the rudest character possible, that the thread is coarse and uneven, and that no two skeins as a rule will be found to correspond in quality, it will easily be understood why *muga* is incapable of competing with the finer and not more expensive silk of Bengal; and, indeed, in Bengal itself the silk-reeling business has for some time been in a stationary or decaying condition. *Eri* thread is still more "uneven, gouty, and knobby," and would probably be regarded by the English manufacturer as unfit for employment for any purpose. From the export of cocoons, on the other hand, there may possibly be something to hope. The manufacture of silk plushes and similar fabrics out of waste cocoons imported from India or China is a flourishing branch of the silk industry in England, and although China has hitherto been the principal source of supply, there is no reason why Assam should not contribute large quantities of an article which is produced with so much ease in the valley of the Brahmapootra.

.

THE kind of thing that is wanted is described in the following words by one of the English gentlemen engaged in its manufacture:—

The class of silk called *spun* silk is made by a combing and carding process, out of the refuse of *thrown* silk, and out of cocoons that are damaged and not windable, and out of *pierced* cocoons, as we name those from which the moth in the order of nature has escaped. It is in this latter condition that I think wild silks should be found somewhere in India, and this is what I principally want. I do not wish to wind such silk, but to *spin* it into fine thread. It does not matter how broken and rough it may look, or how much it is knocked about, torn, or crushed. I only want it as free as possible from the dead bodies of the worm, and of such foreign matters as sand or branches. It will not look like silk at all, till the gum and dirt are boiled and washed out of it. You observe I ask nothing from India that requires skilled labour or machinery; only to collect the raw material in a state in which it must be almost valueless in India, and let us by our superior mechanical appliances make something of it here. *Eri* I like best for its whiteness. I believe it breeds frequently, but I do not believe any amount of cultivation could get *thrown* silk out of it. I mean, of course, to be of any commercial value. *Muga* is darker than *eri*, but has some other properties that are valuable, principally as a *spun* silk. No *eri* or *muga* waste cocoons have, as far as I know, ever been sold in the London market. I only know of trifling samples having been tried, too small to base any value upon. *Tusser* waste silk, however, is regularly sold in London. It comes both from India and China; the price is about 1s. 6d. the pound, and it is very dirty. I should say the *eri* and *muga* would be much more valuable.

In a letter from another firm engaged in the same business, I find the raw material described as "pierced or spoilt cocoons, — cocoons from which the moth has worked itself out and escaped," while cocoons with the chrysalis inside them are not wanted at all.

Now, in comparison with other parts of India, Assam seems to possess superior capabilities for supplying a demand of this nature. The conditions of *tusser* cultivation in Bengal, as described by the Commissioner of Chota Nagpore (supplement

to *Calcutta Gazette* of 31st October 1883) appear much less favourable than the conditions of *muga* cultivation in this province. He calculates that a man can tend fifteen trees yielding 450 cocoons in an ordinary, and 1,500 in a bumper year, such as occurs occasionally: and the selling price of the cocoons is 160 the rupee. The *muga* cultivator in Assam would obtain more than 3,000 cocoons from an equal number of full-grown *sum*-trees, and the price of the whole cocoons is about 600 the rupee. It follows that Assam ought to be in a much better position to supply cocoons to the English silk-spinner than the principal *tusser*-producing districts of Bengal. If a similar calculation be made with regard to *eri* cocoons, the result appears still more favourable.

.

No attempt seems ever to have been made to develop the cultivation of *muga* for the English market, but we have the record of Mr. C. H. Lepper's experiments with *eri* in the Lukhimpore district about 1872-73. Mr. Lepper was commissioned by Messrs. Lister & Co. to take up land, and try the experiment of rearing the *eri* worm on a large scale, so as to thoroughly prove the practicability of procuring silk of sufficient quantity to make the business pay. His choice of a site in the southern portion of Lukhimpore was perhaps an unfortunate one, as the worm is much more widely cultivated on the confines of Kamroop and Durrung. He found the climatic conditions exceptionally favourable, the supply of food abundant, and worms so peculiarly adapted to breeding as to suggest the belief that with proper care a constant rotation of crops could be obtained, so that the operations of breeding and spinning might go on uninterruptedly all the year round. Some experiments made with the cocoons also pointed to the possibility of considerably improving them in size and quality. But the difficulty of procuring labour, and its costliness when procured (local labour being quite inefficient) were so great as to deter him from advising Messrs. Lister and Co. to continue operations. His own estimate was that the cost of suitable buildings on even a moderate scale, to replace the native style of house, which is not proof against damp, rats, or insects, would not be less than £3,000. A similar attempt was made some six years ago by a European in the neighbourhood of Rangia, in Kamroop, but he was compelled to abandon it after losing his entire crop by disease.

.

IN the face of these precedents, the prospect of *eri* cultivation on a large scale, either by the Government or by private enterprise, is not encouraging, and the difficulties are still greater in respect of *muga*. But the case is different with the native breeder, who spends nothing, and therefore can suffer no loss. Were a market once opened for *muga* and *eri* cocoons at fixed rates and in unlimited quantity, it is probably enough that the cultivators would be glad to bring their cocoons to it, and that under the stimulus of a regular and certain demand, the supply would soon begin to increase. Only the waste cocoons—the perforated cocoons through which the moth has been allowed to eat its way—would be required, and the seller would not even be put to the trouble of boiling his cocoons as he does now before offering them for sale. The practicability of getting up a supply for the English silk-spinner in this way depends, of course, upon the price which he finds it worth his while to offer for the article supplied. In November 1883, I despatched a small consignment of *eri* cocoons to a silk-spinner in England, who has sent me samples of the yarn prepared from them, and asked for a large supply. It is not safe to enter into any minute calculation in these matters, but it seems to me that a price of 1s. per pound for either *eri* or *muga* cocoons in London would repay the exporter. The great want at present is free communication between the exporter and the producer. The indolence and suspiciousness of the Assamese ryot have to be overcome, and this can be done far better by private enterprise than by Government agency, though the latter may be able to help private enterprise in pushing its way in Assam. As is, the demand for waste silk in England has already begun to attract a trade in *eri* cocoons, and some 400 to 500 cwt are exported annually from Goalpara to Calcutta for shipment to London, but this supply is very far from adequately representing the productive capabilities of the Assam Valley.

THE following extracts from "Indian Fish and Fishing," by Francis Day, F. L. S., Indian Commissioner at the Fisheries Exhibition, are well worth reproducing for the benefit of our readers. The result of the investigations I conducted in India led me to conclude that wherever a good local demand existed for fish, the fishermen were in a prosperous condition. Wherever salt was dear the fish-curers' trade was restricted or destroyed, and as a result the fishermen were in a depressed state. That fish salted with taxed or monopoly salt is a luxury for the rich, the sick, and for export; that such as is prepared with salt-earth keeps badly and predisposes to disease. That in many localities where the salt laws were rigidly enforced the poor had to consume their fish putrid, or simply immerse it in sea water and then dry it in the sun. In short, it was patent to most that the depressed condition of the fishermen and fish-curers' trades was to be found in the incidence of the salt-tax, and that those who deprecate any interference with the poor fishermen, on the ground of their miserable state of destitution, must be unaware of their real condition. One cannot suppose such advisers to be oblivious of the distresses of those among whom they reside, or would desire to feed the poor on putrid fish, on the consideration that the realization of the salt revenue is of much greater importance than the lives, health, and comfort of their fellow-creatures. Assisting fishermen with money, boats, and nets would be insufficient to place the sea-fishermen and fish-curers' trade in a healthy state, while, if it is in a healthy condition, such advances are unnecessary. Expensive salt is beyond the reach of the majority of the fish-curers, it is ruinous to their trade, and in the ruin of the fish-curer the fishermen must eventually participate. It is to be hoped that the endeavours now being made to reintroduce prosperity among this numerous class will be productive of the greatest benefit not only to themselves, but by augmenting the food for the general public.

.

FRESH-WATER fisheries differ in many respects from marine ones; while, wherever any quantity of fresh water exists in the East, there we are almost certain to find fish, and this from a sea-level to nearly the summit of the highest mountains. Consequently fishing is had recourse to, in various manners, in rivers, irrigation canals, lakes, tanks, ditches, inundated fields, and swamps. The importance of such fisheries is not solely in a ratio as regards their productiveness, but also in accordance with the character of the adjacent people as to whether they are or are not fish-consumers; while the sparsity or the reverse of the population has also to be taken into account. Should no regulations be in force for the protection of inland fisheries and other circumstances be equal, that district which is most densely populated by man will be least so by fish. Individuals can more readily live by fishing than by agriculture, as the trouble of capturing the finny tribes is considerably less than that of tilling the soil. But unregulated capture is simply catching food without a thought respecting future supply. Fish have been endowed with certain means of increase and protection; the number of their eggs may be enormous and sufficient to counterbalance natural waste. The operations of man, however, are in excess of natural waste, consequently such a destructive agency requires to be kept in some check. In India certain forms of fish keep guard over their eggs, and likewise over their fry, in order to afford them protection from their enemies. When man increases, watery wastes (wherein the fish had been protected by grass, reeds, bushes, and the roots of trees) become drained and cultivated; predaceous man increases his means of destruction; an augmented population, possibly assisted by the unscrupulous manufacturer or miner, pollute the previously wholesome water, and a diminution of the finny tribe becomes apparent to the investigator.

.

With an increasing fish-eating population, an increased supply of fish is a self-evident necessity, and this must be provided for by augmented captures or dearer prices, the latter acting as a check on the poor, by more or less placing it out of their reach. This latter result may, consequently, eventuate in gradually diminishing the physical strength of the people by decreasing their food, a proceeding which will sorely bear

examination. It is clear that a greater supply must be met from one or two sources, either from fisheries which previously have been insufficiently worked, or by overworking such as exist, by means of capturing, for present use, those which ought to be left for a future season. Even if the extent of the water is so great, and the contiguous inhabitants so few, that this result need not be anticipated for several generations, still populations, under good systems of government, have a natural tendency to increase. Means of carriage generally improve with time, and should neither regulation nor care of the fisheries be attempted, disastrous results must eventually be arrived at, unless the finny tribes by means of artificial propagation are kept up to the required numbers. Fish appear to have but few friends but many enemies, and investigations as to their condition but too frequently end in giving increased license to their captors. We see interested parties and philanthropists (so-called) exclaiming against the hardship to the poor in not allowing every available fish to be secured. The majority of our law-makers are content to allow fish to shift for themselves, and to leave the fishermen to be controlled simply by their own consciences. To-day's market it is hoped will be supplied; sufficient for this season, it is believed, may be obtained, so to-morrow's wants are left to be met as they can, until the time arrives when depletion of fisheries becomes obvious, when, if the fault cannot be laid upon meteorological or other conditions, something has to be attempted.

.

IN Native States fish have obtained great consideration, more so perhaps in ancient than in our own times. Thus, in Mysore, in the time of Hyder Ali, very stringent fishery laws existed; whereas, at the present day, about two-thirds of the population of some divisions of the country occasionally add fishing to their other occupations, nearly every villager possessing a fish-net or trap, to be employed as occasion or opportunity arises. Now fisheries are open to all; a fisherman's calling is no longer a profitable one, mainly due to the fisheries being depopulated. When whole districts were let to contractors, they were not so short-sighted as to permit an indiscriminate destruction; but now everybody does as he likes, when he likes, where he likes, and how he likes. Thus, it has come to pass, that among the animal productions of India fresh-water fish meet with the least sympathy, and the greatest persecution, many forms having to struggle for bare existence in rivers which periodically diminish to small streams, or even become a mere succession of pools, or in tanks from which the water totally disappears. They have their enemies in the egg stage, in their youth, and during their maturity; but among these man is their greatest foe, as any one who desires a fish diet captures these creatures whenever and wherever he gets the chance, irrespective of season, age, and size. In certain districts they simply appear to exist solely because man and vermin have been unable to destroy them.

.

FISHERIES may be let to a contractor, and if their extent is large, he takes partners or sublets portions; sometimes he employs servants, who are paid partly in money, or food, clothing, and lodging, and partly in a share of the captures. In some districts the fisheries, or a portion of them, are declared free, but a license fee is charged to the fishermen. Or the general public is permitted to take fish for home consumption, but not for sale. Lastly, no regulations at all may exist, due to the general poverty of the fisheries, peculiar difficulties in their capture, or the general impecuniosity of the inhabitants. When the public have more or less depleted fisheries, the fishermen become poorer and poorer, unless they turn to other sources of obtaining money; at first, no doubt pleased at the remission of rents and the removal of all restrictions upon fishing, they employ redoubled energy, and thus augment their immediate profits. But soon the general public find that nothing precluded their fishing in any way they please; the markets become glutted, and the price may fall from the want of purchasers. But after two or three years fish become scarcer; fishing is no longer remunerative; removing the rents

from fisheries, and throwing them open to the public will not decrease the price of fish. The rates ruling in India are comparative to what obtains for meat and other articles of animal food. Fishermen living on free fisheries, do not dispose of their captures below market rate, any more than farmers who possess rent-free farms sell the produce at less than their neighbours; while, perhaps, of the widest spread fallacies of the present day, is that permitting fisheries to be free of rent and unrestricted by regulations, is beneficial to the fishing population. If the fisherman benefits, the purchaser does not, and their misapplied energy eventuates in nothing but small fish remaining. The young have to be raised from ova of such as are merely one or two seasons old, while the younger the parent the smaller the eggs, and this is probably one mode in which races of fish deteriorate.

AGRICULTURAL BANKS IN THE MADRAS PRESIDENCY.

A FEW months back some of the residents of Cuddalore, in the Madras Presidency, had memorialized the Indian Government, on the subject of establishing an Agricultural Bank in that part of the country. The Government of India desired to be informed what special facilities and powers the memorialists wish to obtain in the matter of the establishment of these Banks, at the same time asking the opinion of the Madras Government on the memorial. A reference was made to the promoters of the scheme, who submitted that the special powers and facilities which they deem essential to the success of their enterprise, and for which they desire to have legislative sanction, are seven in number and are as follows:—(1) That the advance made on the security of lands by this Bank should have priority over other encumbrances except that of Government dues; (2) That the claims of persons having prior lien on the property, on the security of which this bank has advanced any loan, should be set aside in a Court of law, provided that the bank has invited such persons by means of advertisements, or in any other way the Government may determine, to state if they have any claim upon the landed property, and, in the absence of information of any such claims, the advance has been made; (3) That the Court be authorized to enforce the terms of any document for the recovery of advances made by this bank by summary process, provided the bank has taken the precaution of registering such documents and paid the advance-money in the presence of the registering officer; (4) That the bank be authorized to proceed in the manner provided in Act II of 1864 or VIII of 1865 for the recovery of advances, provided that the documents are duly registered; (5) That the tahsildars be authorized to give information to this bank of any default in the payment of Government dues on lands mortgaged to this bank, provided that this bank has given due notice to the tahsildars of the transactions in question; (6) That the bank be authorized to sell by public auction moveable property pledged to them as security for loans in cases of default of repayment of the loans within the stipulated time, provided that due notice has been given to the owner thereof; (7) That this bank be authorized to deposit in the Government Treasury all securities deposited with them as mortgage for loans. The Collector of South Arcot and the Director of Revenue Settlement and Agriculture are of opinion that some of the concessions asked for might be granted without compromising the existing laws on the subject, so that while the interest of the ryot was respected the wishes of the promoters would be met. The Board of Revenue, however, throw cold water on the scheme, by remarking that Act XIX of 1883 (Land Improvement Loans Act, 1883), under which money can be borrowed from Government upon very liberal terms, will probably meet the requirements of those agriculturists who may be willing to take loans upon definite terms in regard to repayment. It is unlikely that the petitioners will be prepared to make advances upon terms so liberal as those contemplated by Government under the new system, and since the concession which they seek in favor of the Association would place the Bank in a position not very different from that occupied by Government in regard to recovery of loans, it seems improbable that resort would be had

to the Company in preference to Government. The Government of Madras in reviewing the proceedings of the Board and the correspondence on the subject observe:—The two most important privileges asked for by the memorialists to enable them to lend money to agriculturists at low rates of interest are (1) that the claims of the Bank should be declared to be the first charge, after revenue due to Government, on land mortgaged as security for its loans, provided that no prior claims are brought forward, within a time to be specified, in pursuance of a notice inviting claims issued by the bank before accepting the security; and (2) that the loan, when not repaid on the due date, shall be recoverable by summary process by the Courts, if the document evidencing the loan has been registered and the money lent paid in the presence of the registering officer. Mr. Wilson is in favor of granting both these concessions, and specially approves of the proposal to give registered documents the force of decrees of Courts.

As regards the first of the proposals, the Government do not think that a general notice would give adequate protection to third parties. Notwithstanding the stringent provisions as to the publication of notices of revenue sales under Act II of 1864, it sometimes happens that parties interested know nothing of what is going on and lose their rights in consequence. The proposed operations of the bank are not to be confined to loans for land improvements; but it is the fact that the land is to be improved by the expenditure of the loan, which alone justifies the preference given to the loan debt above all other charges on the property. For land improvements, the Government are ready to lend at very low rates, and the bank is not required at all. His Excellency the Governor in Council is also unable to accept the proposal to give registration the effect of a decree of a Court. Registration can secure the genuineness of documents, but the registering officers cannot settle such questions as the right of the borrower to charge the property, the true interpretation of the document, or the plea of satisfaction in whole or in part. It is impossible to take away from debtors the power and opportunity of raising these questions; and if they are to be dealt with by the Courts before issue of execution on the document, the procedure might as well be by regular suit. Similar objections apply to the proposal of the memorialists to enforce the terms of loans by process under Madras Act II of 1864 or Act VIII of 1865. The memorialists say nothing as to superintendence or restriction of their operations, except that the rate of interest to be charged shall not exceed 9 per cent. It is evident, however, that very considerable powers of inspection and interference will be required to prevent abuse. The suggested restriction as to maximum interest could be readily evaded. In view of these considerations, the Government of Madras are decidedly of opinion that the bank should not be granted any privileges involving interference with private rights. The agricultural population of this Presidency are not in such a state of impoverishment and indebtedness, nor is their need of assistance so great, as to require legislation of such an exceptional character. The provisions of the Transfer of Property and Registration Acts secure sufficiently complete registration of documents affecting interests in land, and render it easy for the bank to ascertain the existence or non-existence of prior charges. The risk of false claims being set up, which is the basis of the proposed concession, is not great. Reasonable facilities might, however, be given to the bank to search the registration books, and the registration fees might perhaps be remitted in their favor. The Revenue officers might be instructed to comply with applications for information as to the revenue due on lands offered as security. The Government would also not object to valuable securities belonging to the bank being deposited for safety in Government treasuries. The bank might be empowered to sell immoveable property mortgaged to them on their own responsibility, as is provided by Section 69 of Act IV of 1882, and like power is already provided for as regards moveable property by Section 176 of the Contract Act. But the grant of any privileges affecting directly or indirectly private rights might, in the opinion of his Excellency in Council, have an effect the reverse of what is intended; and, by rendering titles to landed property more uncertain, raise the rate of interest for loans not obtainable from the specially favored bank.

THE BENGAL HARVESTS.

We have seen that the Government has brought forward, at the last moment, and without any enquiry of its own, an estimate of the Famine Commission, to the effect that the annual value of the gross produce of these Provinces is 103½ crores of Rupees. It tells us that this estimate was subjected to the examination of a Committee of 'experts,' meaning hereby, of course, that some trust may be placed in it, although it is obliged to follow up this assurance by admitting that the value of the dairy produce (35 crores) has been omitted therefrom. We should have heard nothing of this omission, but for the pointed attention the *Statesman* has repeatedly drawn to the fact, that in all these estimates our 'officials' have uniformly failed to take the dairy produce into the account. The worth of the estimate and of the checking to which, we are told, it was subjected by 'experts,' may be accurately gauged by this naive confession. But it is not the dairy produce only, that has been lost sight of, but the fact that the Provinces produce some 30 crores of exports a year! The Government is badly served by its Secretaries, or these astounding blunders could not occur.

Let us now revert, however, to this famine estimate, that the gross value of the harvests is 103½ millions a year, and pass by for the moment all notice of the dairy produce and the exports. We are then confronted with the following astonishing fact, that these 'experts,' whoever they were, arrived at the conclusion that, with 70 millions of people to be fed, and 70 millions of acres under tillage, the harvests of 1883 are just what they were ninety years ago when the population was but 25 millions, and the area under tillage comprised but 30 millions of acres, where there are now 70. For if the reader will turn to Mr. COLEBROOKE'S treatise at page 15, he will there find that Mr. COLEBROOKE estimated the gross harvests of that period to be as follows:—

Gross harvests, 1793-94.		Rupiyas.
<i>Mans.</i>		
150,000,000 of rice, wheat, and barley, at 12 annas	...	112,500,000
60,000,000 millet, &c., at 8 annas	...	30,000,000
90,000,000 pulse, at 10 annas	...	56,250,000
		198,750,000
Seed reserved for the following season, 43,000,000 mans	...	23,380,000
		227,130,000
Oil seeds	...	12,000,000
Sugar, tobacco, cotton, &c.	...	70,000,000
Sundries	...	20,000,000
Gross produce of land, Rupiyas	...	329,130,000

Now, Mr. COLEBROOKE, as we know, was a very exact enquirer and the result of his enquiries and observations was the conviction that the gross produce of the land, at the time of the Settlement, was 33 crores of Rupees. The reader has only to look at the prices in this estimate, to see that the change in the value of money has been so great, that, expressed in the currency of to-day, the 33 crores require to be multiplied 3 or 4 times over, when we reach the remarkable fact that the Secretariat experts have discovered that 70 millions of people are fed to-day off a tillage of 70 million acres, that really produce no more than the 30 millions under cultivation, for the 25 millions of people subsisting in 1793. In neither case is the dairy produce or the export produce comprised, but we are to accept it as a fact, 'an approximation,' as Mr. McDONELL calls it, 'to the truth,' that the harvests of these rich and crowded Provinces to-day, are just what they were 90 years ago, when two-thirds of the land were waste, and the Provinces but sparsely populated. Are not these exposures as discreditable as we declare them to be?

But we may throw a little more light upon the subject, if we look at the harvests of another land, the soil and cultivation of which so closely resemble those of Bengal as to be nearly identical. Great pains, then, have been taken in the last seven or eight years, in consequence of the exigencies of Egyptian Finance, to ascertain the gross value of the Nile harvests, for the very purpose of ascertaining the pressure of the rental (or *khiraj*, as it is there rightly called) upon the produce of the land. The entire population of Egypt is but 5½ millions, and the whole cultivated area of the land comprises but five millions of acres, against the 70 millions of people and 70 millions of

acres in Bengal. Can the reader then believe it to be possible, that while the Government of Bengal is telling the world its belief, that the gross value of the rich and varied harvest of these Provinces is but 103½ millions sterling a year, Egyptian statesmen and European and Anglo-Indian experts, have come to the conclusion that the gross value of the harvest there is 41 millions sterling a year, of which the exports amount to 13 millions sterling? Here are the figures:

Area under tillage.	
Oushr Land	... 1,320,000 acres.
Khiraj	... 3,514,000 "
Abadieh	... 620,000 "
Total	... 5,463,000

—against 70,000,000 acres in Bengal. But Egypt grows neither indigo, nor silk, nor opium, nor tobacco, nor tea. Her staples are maize, wheat, pulse, barley, cotton, rice, lentils, sugar (80,000 acres only) flax, and clover, and the value of her harvests is £44,800,000 a year. Her dairy produce and garden produce are not included in this estimate, and the population being small, they are of little account, compared with the same items here.

So large has the strictly urban population of these provinces become in the last ninety years, that the value of the dairy, market garden, fruit, and fodder produce must be enormous. And the local Secretariat positively puts forth an estimate of 103½ millions, as an 'approximation' to the truth, admitting with the next breath that 70 millions have to be added for dairy produce and exports, overlooked (!). Our estimate of the gross harvests at £20 to 250 crores is undoubtedly too low, as we have been seeing for weeks past. And is it no reproach to us, that after 130 years of rule, we are as ignorant of the simplest economic facts of our position, as they were in 1793? We have had a Bill for settling the right pressure of the Rental upon the Land under discussion for 5½ years, and it is only the journalist that can make a reasonable estimate of the position. Common sense should have told the Government that the very first step to be taken, in attempting to regulate the rental, was to institute an exact enquiry, as was done in Ireland, into the pressure of the existing rents and assessments on the yield of the land. To go on with the Bill, as the Government is now doing, without the slightest knowledge of what the land produces, and making ludicrous guesses at it that require to be adjusted by items of 30 millions at a stroke, is really monstrous. It is clear enough from the whole tenor of the Bill, that the men who framed it, believed the Zemindar to be exacting half the produce or more, and so they enacted that he should be restricted to a third or a fourth. It never occurred to them that as they knew the rental to aggregate 13 crores, the gross harvests could only be 26, if the rent were half the produce! Exact enquiry, we are convinced, would shew that the rents are not 1-20th of the produce, when the aspect of at least one-half the Bill can provoke nothing but laughter.

Miscellaneous Items.

A GERMAN squatter in Victoria has successfully made ensilage for the last three years in a slab hut, instead of a pit.

THE latest district reports represent that the crops are flourishing, and prospects excellent, in the Upper Provinces.

WE hear that the ceremony of commencing the new Baroda Water-Works was performed by the Maharaja, on the 8th of January.

It is believed that the scheme for the improvement of the Bhangur Canal and Tolly's Nullah will shortly obtain the sanction of the Supreme Government.

WE are glad to hear that the rubber crops in South Behar have been splendid this year. Relief measures will not, therefore, it is hoped, be necessary later on.

THE new appointment of Commissioner, or Director of Settlements, in the Punjab, will most likely be filled eventually by Mr. Denzil Ibbettson, C. S., at present officiating as Director of Public Instruction.

THE merchants and traders of Kurrachee have forwarded to the Municipality a memorial showing their grievances, on account of the levy of a duty on imported piece-goods.

ACCORDING to the report of Mr. Poggson, the Government Astronomer, the total quantity of rain collected at Madras during last year, was 79 inches, the average due for the same period being 49 inches.

A SINGULAR fatality is recorded in last week's Bombay season reports. Seven shepherds are stated to have lost their lives at Athni, in the Belgaum district, by being struck by "hailstones of the size of a cocoanut."

IN accordance with the orders of the Secretary of State, service for leave and pension, in the case of Forest State Officers appointed in England, will in future be held to commence from the date on which their pay begins to accrue, *i. e.*, from the date of their arrival in India.

THE sum raised by the Municipality of Bhagulpore, for the construction of the new water-works, not being likely to prove sufficient, the Bengal Government has ordered that the work shall be constructed by the Public Works Department, as an ordinary provincial work, the Municipality only contributing to the extent of the money raised.

THE Guzerat Agricultural Exhibition, including perhaps a horse show, will be held this time at Noriad, on the 2nd March next. It is to be under the joint patronage of his Excellency the Governor of Bombay, and of his Highness the Gaekwar of Baroda, each of whom has subscribed a thousand rupees. His Excellency the Governor will, if possible, be present to open the show.

SIR W. H. F. MITCHELL, President of the Victoria Legislative Council, died on the 24th Novr., after a very brief illness, caused by eating poisonous fish. He had been in his usual place in Parliament on the previous Thursday, and seemed then as vigorous, physically and mentally, and as cheerful, as he has been for some years. He was one of the earliest Victorian colonists.

DR. WILLIAM KING, of the Geological Survey of India, in an article on Artesian wells in the *Madras Mail*, lately says that Madras has a fair stretch of alluvium and water sheets in it, and recommends that experiments similar to those at Pondicherry, where they have been successful, may be tried here either by private enterprise, the Municipality, or Government, since the subject of the Madras water-supply has brought up the question of Artesian wells.

By a notification in the N.-W. P. *Government Gazette*, the Pilibhit and Kumaon Forests are closed against hunting, shooting, and fishing from the 1st of January, 1885, to the 30th June following. It is also notified that entrance to these closed forests is prohibited to the public, except along the regular forest roads, during the above mentioned period. Further, the forests are closed against grazing from date of the notification till further notice.

THE Collector of Customs, Bengal, gives his opinion, in his annual report, as to why the Australian wines, samples of which were shown at the late International Exhibition, are not like to become popular in India, unless their character is considerably modified. In Mr. Armstrong's judgment these wines are too strong and too sweet; they do not stand the climate; and their names, borrowed from those of well-known European wines, suggest expectations which their quality fails to satisfy.

ACCORDING to the latest China papers, in the Hong Kong opium market, a good demand has prevailed for both kinds of Bengal drug, during the past fortnight, and prices have advanced; Malwa has been in moderate request at steady rates; the inquiry for Persian has continued, and values have been further enhanced. At Shanghai a considerable business has been passing in Patun, and the quotations for that drug and Benares have improved. The market for Malwa has remained quiet, at unchanged prices.

WE hear that a good deal of sensation has been produced in the city of Lahore, by the fact becoming generally known, that the *halewis* use "refined" sugar in preparing sweetmeats. A meeting of the Hindu Sabha was held on the 30th ultimo, at the Sikha Sabha hall under the presidency of Raja Hurbans Singh, and an unanimous protest was entered into against the practice. A committee was appointed to carry out the views of the meeting; and we hear that in the city, the *halewis* have been throwing into the streets the condiments prepared by them, and allowing no one even to touch the same.

SOME of the villagers of Kudicadoot cut the Vernaum tank bund, on the night of the 7th ultimo, and only the fortuitous circumstance that they left the breach with vertical sides, and the sides falling in nearly filled up the gap, averted a serious disaster. The tank is the largest in the Madras Presidency, and if the breach had proved effective as intended, the damage caused must have been enormous. The water would have submerged the whole taluk, and washed the village of Chidambaram away. The partial breach was discovered early the next morning, and promptly repaired, and energetic measures are being adopted to trace the offenders, and bring them to justice.

A FEW days ago a Malay at Pangeran, while walking along a narrow path through a swamp, came in contact with a python, which, after biting his leg, coiled itself round it; he had, however, presence of mind enough to seize the reptile by the head, and by forcing its jaws open until they were dislocated, he disabled him. On arriving at the village the alarm was given, and the people turning out, found the snake, which had crept into the scrub, and despatched it. It was 18 feet in length, so the man must have had a very narrow escape.

DEFINITE orders have been issued by the Madras Government regarding the destruction of elephants, under which, permission for shooting will only be granted in the case of rogue elephants, and in those cases in which the numbers of wild elephants may be found to be getting so numerous, as to be a cause of annoyance or terror to ryots and others. Applications of any other nature will meet with absolute refusal on the part of Government. Orders to this effect have been issued to all the Collectors, and the following paragraph has been added to the Standing Orders of the Board of Revenue:—"Permission to shoot elephants, not being rogues, will invariably be refused, unless when it is reported that they are dangerously numerous."

THE largest percentage of paper fibre from the different kinds of woods is that yielded by the mile-tree, or *tillia Europæa*, viz., 38.16 per cent. The next largest per cent is derived from the black alder, 37.82, and these are followed, in course, by the willow 37.81; the horse chestnut, Italian poplar, Canadian poplar, white poplar, fir, aspen, bamboo, white pine, alder, acacia, birch, red pine, ash, elm, pitch pine, osier, oak, filbert, henth, walnut, &c. Among the herbaceous plants, founteuan takes the lead, furnishing 46.17 per cent, and to this succeeds bent grass, 45.82; canary grass, 44.16; rye, 44.12; wheat, 43.14; marsh rush, 41.70; reed, 41.57; maize, 40.24; blue flag, 40.07; marsh grass, 38.80; barley, 36.21; oats, 35.08; sedge, 33.86; New Zealand flax, 32.71; asparagus stalks, 32.56; wild broom, 32.43. Most of these substances have at various times been employed in pulp-making.

RESOLUTION ON THE REPORT OF THE COMMITTEE APPOINTED TO CONDUCT A TRIAL OF THE MACHINES AND PROCESSES FOR THE EXTRACTION OF FIBRES.

REVENUE DEPARTMENT—MISCELLANEOUS.

Calcutta, the 30th December, 1884.

RESOLUTION.

READ—

The Report of the Committee appointed by the Government of Bengal to conduct a trial of machines and processes for the extraction of Indian fibres.

By a Resolution dated the 5th September 1884, the Lieutenant-Governor was pleased to appoint Mr J. W. Hanlon, Superintendent of Jail Manufactures, and Mr. Liotard, of the Revenue and Agricultural Department of the Government of India, to conduct such a competitive trial of machines and processes, for the extraction of Indian fibres, as might lead to the introduction into this country of a cheap, simple, and portable fibre-extracting machine. It was also stated in the Resolution, which was published in the *Calcutta Gazette*, that if the number of machines entered were sufficient to produce a satisfactory competition, the Government would be prepared to award a sum of Rs. 2,000 in prizes. The Report of the Committee, which has now been received, forms a valuable contribution to a subject of great commercial interest, and the thanks of the Government of Bengal are due to Messrs. Hanlon and Liotard, for the care with which they have conducted the trials, and to the Agri-Horticultural Society of India for the assistance they have given, by supplying the fibres used in the experiments. The Lieutenant-Governor accepts the finding of the Committee, that the Universal Fibre cleaning Machine invented by Mr. H. C. Smith, manufactured and improved by Messrs. Death and Ellwood, of Leicester, and brought forward by the General Fibre Company of London, is the best of the nine machines entered for competition. The mechanical working of this machine appears to have been rapid and effectual; and the further question, whether it can be profitably introduced into Bengal, may well be left to be decided by the commercial public, who have already shown considerable interest in the trials. The value of the fibres extracted, and the uses to which they can be put, are also matters to be dealt with by experts and commercial men in the course of their ordinary business, and no further action on the part of Government appears to be called for. Should it, however, be afterwards found that the facts ascertained in the recent trials are not complete enough, to enable the

mercantile public to form a fair judgment of the commercial prospects of the successful machine, further trials may be conducted under the superintendence of the Agricultural Department. In the meantime, in accordance with the recommendation of the Committee, the Lieutenant-Governor has much pleasure in awarding a prize of Rs. 2,000 to the General Fibre Company of London, for Messrs. Death and Ellwood's machine. This resolution and the Report of the Committee will be published in the *Calcutta Gazette*.

By order of the Lieutenant-Governor of Bengal,

A. P. MACDONNELL,
Secretary to the Government of Bengal.

WATTLE CULTIVATION AS AN INDUSTRY.

A WRITER, subscribing himself ACACIA, sends the following notes on wattle cultivation to the *South Australi Register* :—

It is no exaggeration to say that the various kinds of acacia usually spoken of under the general term of wattles, form one of the most valuable of the natural products of Australian soil. The bark of these trees has for years occupied an important position in the tanning industry, and it may safely be said that the estimation in which it is held is on the increase rather than declining. Side by side with this fact is the important and somewhat distressing circumstance, that the yield of bark appears not only to be on the decrease in quantity but also in quality. The reason of this falling-off is not far to seek. In the early days of wattle-stripping the procurement of sufficient bark to meet all requirements was accomplished with comparative ease, inasmuch as wattles were to be found growing here, there, and everywhere. So widespread was the natural habitat of the various sorts of acacias in South Australia, that within the settled districts at all events, it is more difficult to define localities where it did not and would not grow, than to name localities where it would and did thrive. A very large proportion of the unalienated lands was more or less covered with wattles, and so great was the area, that strippers could find a great deal more bark than they had time to strip. Gradually, however, as these lands were parted with by the Crown, the natural growth was burnt off to make way for sheep or wheat, until, as is now the case, wattles are considerably reduced numerically, and are only to be found in certain portions of the original area. As a result of this reduction the price of bark went up to a high figure, and the occupation of stripping and selling bark has now become such a profitable one, that strippers pursue their avocation without the smallest discrimination whatever, utterly regardless of the state of the bark when gathered, and quite oblivious to the future supply. Every available wattle-tree within easy distance of a commercial centre is denuded of its bark, and by this wholesale destruction thousands of young trees of perhaps not more than three or four years' growth are cut off before their prime. Such sinful waste cannot be too severely condemned. The bark from these young trees is much inferior in quality to those of mature growth, while the presence of so much juvenile bark in the market, mixed as it usually is with that of better quality, must necessarily tend to lower the value of the whole product in the estimation of the tanning industry. Moreover, it is in the primary stages that the growth of this tree is slowest, and the accumulation of tannin at its minimum. As the tree advances in years the proportional growth per annum gradually but surely increases both in bulk as well as in the production of tannin. Such facts as these should not be lost sight of by all who are fortunate enough to possess natural wattle plantations, and should deter them from permitting any premature stripping on their estates. The time has now arrived when the systematic preservation and cultivation of wattles, as an industry, will be attended with most profitable results—results which I firmly believe will place wattle-growing in the front rank of colonial industries from a lucrative point of view.

Of the acacias which produce the wattle, or mimosa bark of commerce, there are two species which stand pre-eminent in this colony. These are *Acacia Pycnantha* and *Acacia decurrens*. The habitat of the former ranges chiefly from the Adelaide hills north, as far as Beltana. North of Spalding, however, this species assumes a somewhat stunted form compared with what we are accustomed to see in the Adelaide hills. The leaves of this variety are also narrower or more lanceolate than those of the typical form, and the whole tree is easily recognisable from its stem and branches being usually covered with a hoary or glaucous substance. North of the position indicated, the tree is generally confined to the more elevated and hilly portions of the Colony. The typical form is to be found all along the Mount Lofty chain of hills, and the plains from Encounter Bay to north, beyond Barossa; while specimens are to be met with on Kangaroo Island. The other species named, commonly known as the black wattle, is chiefly confined to the south-eastern portions of the Colony. The broad-leaved wattle seldom attains a height of more than 25 feet, with a diameter of 8 inches, although in Brown's Forest "Flora" it is stated that a tree was felled at the Semaphore lately, 35 feet in height and 18 inches in diameter. *Acacia decurrens* grows to a large tree in the south-east, and may there often be met with over 40 feet in height and 2 feet in diameter. The average yield of bark of the broad-leaf may be put down at about 70 lbs. for full, well-grown trees. 7 to 8 years of age; while it is not an uncommon thing to get 500 lbs. from the

black wattle of a similar age. Although the *Pycnantha* is a smaller tree than the other, and is generally less rapid in growth, its bulk is of greater commercial value, owing to its yielding a larger percentage of tannic acid than the black. The *Pycnantha* on an average yields about 35 per cent of tannic acid, sometimes as much as 40 per cent, while the *Acacia decurrens* rarely gives more than 25 per cent. The logical inference therefore points towards *Acacia decurrens* as the most profitable for cultivation, as in spite of the lower yield of tannic acid per ton this disadvantage is fully met by the increased yield per acre. Both trees grow readily in almost any soil, although they seem to have a preference for those of a sandy nature on the surface, supported by a good, yellow-clay sub-soil. When grown upon pure sand, the bark is somewhat deficient in tannic acid, being at the same time of a thin nature and too full of sap to pay well for stripping. It is worthy of note that bark stripped from trees which have been grown upon poor stony ground produces the greatest percentage of tannic acid. This is a fact of great importance, as there is an immense area of country in this colony of this nature, that has hitherto been classed as unproductive land, but which might with great profit be utilized in the production of these trees.

Both species attain their prime condition between the ages of six and ten years, according to locality and quality of soil. When they are grown on the sandy soil, i.e., with clay bottom, they come in for stripping about the sixth year, while on the stony ground it may safely be asserted that the trees would not mature and pay—"pay" meaning the fullest return obtainable from the tree—to strip before the eighth year. Attention may have been called to the immense amount of pig-face country along our southern coast-line on the one hand, and the numbers of rocky patches scattered over the inland country, both of which are suitable for profitable wattle-growing. Touching the methods of cultivation, sandy soil being of a loose nature, the crop should be put in with the plough, by ploughing strips 18 inches broad and 4 feet apart, to a depth of about 4 inches. The seed should then be dropped in about 3 feet apart along the rows. For the first two years after the crop has been sown the ground between the rows should be regularly ploughed or scarified, for the more the land is stirred the more moisture will find its way to the roots, ensuring quicker growth, while ploughing will at all times prove a very valuable ally against fire. The latter item is worthy of note, for I believe I am correct in saying that the various insurance offices do not accept wattle risks, although far safer than the wheat crops so readily accepted. By adopting this method of cultivation, it is calculated that at least two years will be saved in the maturing of the plants than if left to Dame Nature. About the second year pruning must be taken in hand. The rows should be taken in hand systematically, and all large lateral branches which may appear to be interfering with the upward growth of the plant should come off. This operation should be repeated during the third year, after which the trees, partly from the effect of this operation and partly by their proximity to one another, will attain that straight upward tendency of growth which must necessarily be regarded as one of the principal features of a successful wattle plantation, because it is only from straight trees that the bark can be removed with facility, and as a natural consequence the price payable for stripping reduced to its lowest ebb. It may be here noted that the bark which produces the greatest percentage of tannic acid is that which grows on the stem of the tree, and therefore the system of cultivation should be directed to produce as large a bulk of stem as possible, with the least amount of lateral growth in the shape of branches, as is consistent with the proper health of the trees. This can only be obtained by thick planting in the first instance, and early pruning as above indicated in the second place. From careful experiments made, it has been ascertained beyond doubt, that at least 25 per cent more of tannic acid can be procured from a well-pruned tree, than from one left to its own devices, involving that branchy growth which is one of the principal characteristics of the tree.

In the method of planting indicated above, planting at a distance of 4 feet apart has been advocated; but I must here state that many authorities, among whom I may mention the Conservator of Forests, advocate planting at a distance of 8 feet apart in the first instance, and filling up between these rows at the end of the third year. Of course, as wattle cultivation is a thing of the future, experience only can decide on what is at present an open question.

On rocky soil, of course, the same method of cultivation cannot be followed that is feasible on that of a sandy nature, and it is necessary to substitute the spade for the plough. This is, of course, assuming the soil to be of a hard nature. If, however, the soil is of a loose nature it will be found sufficient to sow the seed broadcast after a heavy fall of rain, and the success will be all the more assured if a flock of sheep be run over the area four or five times. This plan has been successfully carried out by the Forest Department in the South-East, at Mount Barr. The next item of importance is the preparation of seed. When this is intended to be covered, either in ploughed ground or by the spade, the plan of scalding the seed has been found to answer the purpose admirably. The simplest way of scalding the seed is to pour almost boiling water upon it. The seed should then be left to soak for about forty-eight hours, and afterwards swathed in a damp bag until quite soft. For broadcast sowing on the surface, however, this does not give good results, because the seed being half-germinated a change of the weather to dryness is sure to result in a stoppage in germination, and consequently, from want of moisture, causes the young shoots to "damp-off," and the seed decays. In order to obviate this, and prepare the seed all ready for germination in such a manner that it will be independent of any sort of weather, the plan has been adopted of cracking the outer hard covering of the seed by means of slow-firing without partial germination so that the seed can be sown upon the ground, and lie there without injury until sufficient

rain falls to make it germinate. In this manner the seed can be sown two or three months before winter, and thus will be in readiness to benefit by the first rains of the season, and consequently the young plants will, before the rainy season is over, have attained such a hold upon the ground that their safety is secured during the following dry season. An explanation of the system adopted will be *appropos*. A high heap of wood is formed and fired; when this has smouldered down to a common expiring condition of red coals and ashes, the seed is thrown into the heap, and the whole stirred up and allowed to remain until the fire goes out. The embers are then raked in a heap, and the ashes and seed bagged together ready for sowing broadcast. There is no doubt that this system is only following out what we see in nature, as all colonists have no doubt noticed that when branches or debris of a wattle-tree have been burned, numerous young trees spring up as a matter of course. Following out this system, it is only necessary when indigenous wattle plantations are conserved to burn up the branches of the trees which have been stripped in order to secure a luxuriant young crop. This method has been successfully carried out at the Mount Brown Forest Reserve.

From recent analyses it appears that although the bark upon the trunk of the tree produces the largest percentage of tannic acid, that upon the branches and twigs, as well as the leaves themselves, and to a certain extent the wood of the tree, contain a fair percentage of tannin. In some cases a greater percentage of tannic acid was obtained from the twigs and branches, than is procurable from best English oak bark (which, by the way, is very difficult to strip). This fact opens a question. Cannot we utilize the tannic acid which, under the present system, is allowed to go to waste on the ground? It is well known to all colonists that hitherto strippers of this bark seldom or never attempt to remove it from the branches, and it has been calculated that in consequence of this, of every one which has been or is being stripped at least one-third of its tannic acid has been allowed to go to waste. Looking at this fact then, and also bearing in mind that however well the trees may be cultivated and pruned under the system recommended, there must always be a considerable quantity of branches and leaves it is thought that when the wattle is cultivated as a commercial crop some measure should be adopted whereby the tannic acid in this debris could be utilized, and the idea has been broached that this might be effected by a boiling-down system. Huge tanks could be constructed, into which every portion of the tree could be placed after being chopped up, and the tannic acid extracted. The plan seems feasible enough, and if it can be profitably carried out, as suggested, possibly it could be improved on so as to place the tree in whole without any chopping whatever. Enormous savings from its adoption must necessarily ensue; less cost than stripping, in the ... place; considerable economy in carting to market; less bulk for export; no loss from pruning. In addition to these advantages the pap would eventually come in either for paper-making or manure. As, however, this plan has not yet been adopted, I cannot submit figures in a balance-sheet. Before submitting an estimate on the probable results of wattle cultivation as an industry, I would like to refer to two pamphlets on the subject already in print. One of these is termed "Wattle Bark," and is substantially a report of the Board of Enquiry appointed in Victoria; the other is termed "Wattle Farming," and is written by Dr. Schomburgk, and published by the Chamber of Manufactures. The former is devoted almost entirely to the rise and progress of the wattle-bark trade of Victoria, and the evidence of some two hundred witnesses who were examined. Into this I will not dip, but an appendix to the work gives a statement showing the profit to be derived from the systematic cultivation of wattles compiled as a result of the enquiries instituted, which deserves attention. I do not for a moment wish to damp the enthusiasm of advocates of wattle cultivation, but I would point out:—

1. That if the production of wattle-bark varies between two given numbers per acre, it is safer in estimating to take the lowest and thus be prepared for casualty.

2. That although there is every reason to believe that "cultivated" wattles could be stripped for at least half the amount paid for stripping those which have been left to nature, still there is reason to doubt whether strippers at the present time make really good wages at the work, and the reduction that would ensue is, therefore, problematical.

The Wattle Commission and Dr. Schomburgk show a profit of over £2,000 per 100 acres in a run of eight years, and arrive at this highly desirable conclusion by estimating a return of 1,213 tons of bark from those 100 acres. On the other hand stripping is estimated at 15s. per ton as against 30s. now actually paid in this Colony, while cartage is put down at 10s. per ton, which, at the present price of wages, I consider, with all due deference, to be at least 30 per cent below the probable expenditure.

As selectors in this Colony are permitted to take up 1,000 acres, I have chosen that area for calculations, and this, according to the Wattle Commission, would yield over 12,000 tons, whereas I put it down at 5,000 so as to be on the safe side. With regard to pruning, the Commission estimate 10s. per acre as against my 4s., and this is the only item in which my figures come under those of the Commission and Dr. Schomburgk. I am of opinion that the item *might* be left out entirely, as the Manager would almost as a matter of course take this into his own hands, and his salary is scheduled. Attention is called to the following facts:—

1. The bark from the broad-leaved wattle is the best in the world; that from the black wattle the second best.

2. The price of bark is rising, and good material is so scarce, that a quantity of inferior bark is used by European tanners out of sheer necessity.

3. Land that will grow wattles successfully is not at present looked upon as worth £4 per acre, the amount set down in the following estimate:—

Estimate of expenditure on a Wattle plantation of 1,000 acres, valued at £4,000, for six years.

	£
Interest on freehold, + compound thereon, ...	2,150
Ploughing and sowing, at 1's. per acre, + interest, ...	835
Pruning second and third years, at 4s. per acre, for the two years, + interest ...	291
Scarifying twice, + interest, say ...	500
Unforeseen expenses, say ...	100
Cartage to market and stripping, at £1 and £1 10s. respectively ...	12,500
Supervision ...	860
Balance of profit over and above good commercial return for capital throughout ...	7,764
Total ...	25,000

Receipts.

Sale of 5,000 tons bark, at £5 ...	25,000
------------------------------------	--------

It will be seen that no credit has been taken for the gum procurable from the plantation, nor for seed. Again, the price of bark has been set down at £5, while it is being sold for considerably over £7 at the present time, and in six years' time must fetch more. There were sales in London of chopped bark at £17 per ton recently. Some believers in wattle-growing advocate sheep being run over the plantations after the first two years, but there are two objections to this, viz., if the ground be thoroughly planted there will be very little grass, and that of an inferior character; and secondly, this plan would interfere with the natural regeneration, involving re-sowing and consequent delay. If the plantation be devoted to wattles, and wattles only, a crop may be relied on every third year after the first six. Yet another point to be remembered. The galls growing on the trees are of considerable value, and could be most profitably utilized on large plantations.

Note.—The above article has been read by me, and I can confidently endorse the general remarks, while I consider that the probable profits shown in the balance-sheet are in no way over-estimated.—J. E. BROWN, Conservator of Forests.

SILOS IN MYSORE

The following is a report of two experiments made with silos at the Mysore Government Stud Farm, at Kunigal, one being an underground silo, and the other a pile of freshly cut forage under an open sided shed weighted with stones, in the manner described by M. Houles, by whom the method was successfully tried in France:—

The under-ground silo was excavated in dry gravelly soil, with no plastering of any kind, but protected from rain by a light thatched roof supported on forked posts.

The dimensions were—

Length ...	16 feet.
Breadth ...	11 "
Depth ...	10 "

with a gradual slope of 4 inches from top to bottom, the cubic capacity being 1,715 cubic feet.

Work was commenced with the silo early on the morning of 28th December 1883, when the grass in paddock No. 1 was mown with scythes, and as it was cut, carted off and deposited in the silo. Before picking the green grass, a layer of paddy straw was placed at the bottom of the silo to keep out the damp, and the grass was then laid on it, to a depth of three feet, great care being taken to have the four sides well trampled down by women. As it was determined to try the effect on different descriptions of forage, the following layers were successively packed and trodden down:—Hurriali grass at the bottom, followed by intermediate layers of chaffed oats, sorghum, hurriali grass, chaffed sorghum, and hurriali with a final layer of chaffed sorghum. On this was spread a layer of paddy straw 3 feet thick, and a platform made of the branches of the bougaya tree was laid on the top and weighted with large rough rubble stones. The work was finished on the 24th January, three days being occupied in weighting, &c. The silo was opened on the morning of the 16th August, seven months having elapsed since it was closed, and the mass having sunk 4 feet in the interval. I had no apparatus for forcing down a thermometer to a greater depth than 3 feet below the surface, but the temperature at that depth was 96 degrees, or 14 degrees higher than that of the air, which was 82 degrees, under cover of the shed. When opened, the top layer of sorghum was a dark brown colour, warm and damp to the touch, and containing so much moisture, that on pressure a reddish juice exuded at once. The hurriali grass was not so moist, but was appreciably damp and looked like inferior hay. The vinous smell from both was most overpowering, and at the edges of the silo the forage was of a different colour, and emitted a very offensive smell.

A cubic foot of the ensilage was cut out at 1 P.M., when it weighed 21lbs., and on being weighed again three hours afterwards, it had lost 3lbs. by evaporation under a strong wind.

In the course of the afternoon, 56 cubic feet were cut out evenly from top to bottom at one of the corners, the contents being so consolidated that it required two men using a sharp spade-shaped steel knife to do it.

The mass weighed 1,099 lbs., or 22 lbs. per cubic foot, and the stones on being weighed were found to be 31,380 lbs. in weight, giving a pressure of 178 lbs. per square foot.

Some of this forage was at once given to the farm cattle, which ate it with avidity, and it was with one or two exceptions readily eaten by all the horses to which it was offered. On the following day the vicious smell had passed off, and was succeeded by an offensive odour, which gradually subsided when the forage was loosely spread out, and when I left Kunigal, it was being consumed by the farm cattle.

A cubic foot of the hurriali grass was brought into Bangalore, and is now quite dry and much like inferior hay, except that it retains a rather peculiar smell.

Cattle and horses eat it at once when given to them.

The pile of forage treated on Monsieur Houles's system, consisted of green lucerne and guinea grass, cut on the morning of 27th January 1884. On that date, a quantity of this was cut and packed under an open thatched shed of the same kind; on the 28th, more was added, and on the evening of that day, the pile was covered in and weighted with stones.

The dimensions before weighting were:—

				ft.	in.
Height	5	3
Length	7	0
Breadth	7	6

but in the course of a month, the mass had sunk to within half a foot from the ground.

On being opened, it was found that, the top and sides were entirely decomposed and smelt abominably, but by gradually cutting away the outside portion, it was ascertained that a portion in the centre was very well preserved. The lucerne was of a dark brownish green, moist and warm, without much smell, and readily eaten by the cattle.

On the 16th August, a cubic foot of this ensilage weighed 42 lbs., and on the 18th, 40 lbs., showing a loss of 2 lbs. by evaporation, the pressure having been 105 lbs. per square foot.

A cubic foot was brought into Bangalore, and when examined a week after, the centre of the block was still slightly heated, the thermometer showing 83 degrees, against 79 degrees, the temperature of the room at the time.

These experiments are useful, but in the case of the underground silo, the work was not carried out exactly in accordance with my instructions, and the result did not appear at the time as satisfactory as was expected.

This silo took a much longer time to fill than was anticipated, and the stones used for weighting were, through a misapprehension of the orders, not covered with earth; the weight both on this silo and on the other was unequally distributed, so that a uniform pressure was not imposed on the whole mass.

The filling of the underground silo was in fact accidentally carried out somewhat in the manner described in a paper in the 'North British Agriculturist,' by Mr. G. Fry, F.L.S., Chobban, headed "The Production of Sweet Ensilage," in which case the product is said to possess all the characteristics of hay, except that it is moist instead of dry.

The cavity from which a portion was taken out was filled with earth at once and closed, as it was considered best to reserve the remaining portion for a further trial.

I returned to Kunigal on the 8th instant, accompanied by Colonel Magrath, the Commissary-General, who was anxious to see the silo, which was re-opened on the morning of the 9th in our presence, and a large portion cut out for examination.

It was most satisfactory to find all offensive odour had disappeared. The vicious smell was not nearly as strong.

A half-inch gas pipe was driven down to the centre of the mass, and the temperature as shown by a thermometer lower down the pipe, was apparently 29 degrees Centigrade, equal to 84.5 Fahrenheit. It however rose in 10 minutes to 32 degrees Centigrade equal to 89.5 Fahrenheit, and the actual temperature of the fodder when the thermometer was brought into direct contact with it in the centre of the block, was 40 degrees Centigrade, equal to 104 degrees Fahrenheit.

Two cubic feet of the hurriali grass were cut out, and each cubic foot weighed separately with the following results:—

No. 1, at 11-30 A.M. weighed	...	22 lbs.
2-30 P.M. "	...	18 "
No. 2, at 11-30 A.M. "	...	22 "

Spread out and dried as hay, weighed 13 lbs., having lost 9 lbs. by drying.

The hurriali grass was slightly discoloured with white mould at the edges, and for about 1 or 2 inches of the surface, otherwise it was moist, sound and sweet, and was eaten greedily by cattle, as well as by the horses.

The chaffed sorghum contained more moisture, but was in admirable condition, and was readily eaten by all the animals except one or two. In some cases, they left the green grass which they were eating and took the ensilage in preference.

Colonel Magrath and myself were entirely satisfied with the success of the experiment, which has shown clearly that green forage can be stored and preserved with less difficulty and labor than hay.

The experiment with the surface silo shewed that green lucerne and guinea grass were more easily compressed than hurriali, and from the condition of the lucerne in the centre, I have no doubt that if the forage had been in an underground air-tight silo, the whole would have been in excellent condition.

The pressure in both of these silos does not, however, appear to have been nearly as great as is recommended elsewhere, and it might apparently be increased with advantage to 300 lbs. per square foot, the weight being calculated and arranged previously instead of being, as in this case, put on by guess.

There seems to be no necessity for cutting up grass, lucerne or guinea grass, but the chaffed sorghum was found to be a very convenient form for giving it to the animals as required; quantities were at once lifted out and carried away in baskets.

A point on which also I entertain no doubt, is that in practice, it will be found better to have a number of silos of a comparatively small size than a few large ones. It is impossible to fill, weight, and close a large silo without great delay and interruption, and the carriage of the grass from a distance adds to the trouble and expense.

The trials to be made in the Amrit Mahal Kowals will, therefore, be with silos of the dimensions recommended by Sir Herbert Macpherson, who has very kindly given me much information on the subject, and who has shown by his own experiments, that the most convenient and easily filled silo contains the grass of from 2 to 6 acres, cut from the land immediately surrounding the silo.

A. C. HAY,

Offg. Mily. Secy. to Mysore Govt.

WHEAT PRODUCTION IN CANADA, THE UNITED STATES, AND ENGLAND.

COLONEL M. J. WHEATLEY writes thus in reply to certain criticisms of his article on the above subject which appeared in these columns:—

"I read with much astonishment the letter of Messrs. Howard, in your paper last week, disputing my statement that self-binding reapers are to be obtained in the United States for 160 dollars, and intimating that they are not to be procured there under 300 dollars. Messrs. Howard are themselves the manufacturers of the self-binders that took the second prize at the recent Shrewsbury trials, Messrs. Hornsby having taken the first prize. I have before me the printed circulars of both firms, as also of Walter A. Wood, one of the principal American firms that competed. All these quote £60 as the price; but there is doubtless a discount. They are, I believe, the best and most expensive machines made, and may be well worth the money asked. In America, however, self-binders have been in general use for many years, are as common as lawn-mowers are in England, and though, doubtless, not possessing all the merits claimed by Messrs. Howard for the English machines, are to be obtained at all prices, of various patterns, and from an immense number of manufacturers. In Brandon, 130 miles west of Winnipeg, an important town in the Canadian wheat field, they were being sold at 150 dol., and were offered to me at that price in September. As stated in my previous letter, prices are generally higher in Canada than the States, and in naming 160 dollars as the usual price in the States, I am satisfied I am not under the mark. I saw immense numbers exhibited in the shows at Montreal, Toronto, and Chicago. It would certainly be strange if they were all sold at as high a price as the best made English ones, containing all the most recent improvements. Messrs. Howard also dispute my statement that wheat is practically never tied by hand in America, on the ground that there are a large number of self-delivery reapers in use there. Very likely, but the sequitur is not apparent. There is a large area in that country of "corn" (by which, I presume Messrs. Howard mean wheat barley, and oats, though in America the term is applied exclusively to maize) which is never tied at all, especially barley and oats. I emphatically repeat my statement that you may travel through America in harvest time from North to South, from East to West, and never see a sheaf of wheat tied by hand, though I am not prepared to state that such a thing may not be still done in some places, especially in the more settled districts. The advisability, however, of using self-binders can only be regarded as one among many elements of the agricultural problem of producing wheat cheaply, which is the really important one for our agriculturist.

"It cannot be too carefully borne in mind that changes of all kinds occur in America with a rapidity that can scarcely be credited in England. Because a machine of any kind was not used in a district two or even one year ago is no ground for assuming that it is not in pretty general use at the present time. The "cutting" of prices, too, goes on in an astonishing manner, and a price twelve months ago is no guide whatever to present charges in machinery, railway rates, or anything else. Farmers, too, who may even a year ago have fancied themselves growing rich may to-day find themselves growing very poor or being rapidly ruined. The fall in prices, of wheat especially, has made these changes more violent than usual even during the last twelve months. Everybody seems to be selling everything for whatever they can get. My belief is, for the reasons given in my previous letter, that the present price of wheat cannot last, but any argument based on the state of things in the wheatfields of the West, even a year ago, must be modified to meet the present condition of affairs. I am well aware that farming is carried on in America under very different conditions in many ways, especially as regards labour supply, to those prevailing in England; but it is, I believe, to a great extent owing to this scarcity of labour that the Americans have become such an extraordinarily industrious and intelligent nation, always ready to adopt every improvement, and to adapt themselves to every change of the circumstances that surround

INDIAN AGRICULTURIST.

CALCUTTA :—SATURDAY, JANUARY 24, 1885.

[No. 4.

Crop and Weather Report.

[FOR THE WEEK ENDING THE 7TH JANUARY, 1885.]

General Remarks.—During the week under report, rain has fallen in a few districts in the Bombay Presidency, in the Central Provinces, and in the Central India and Rajpootana States. There has been rain in varying quantities also throughout the Punjab, and in many districts of the North-Western Provinces and Oudh.

General prospects are fair in the Madras Presidency except in parts of Bellary and Anantapore. In the Kurnool and Coimbatore districts, more rain would be beneficial to the crops, which are withering. Harvest operations continue. In Mysore and Coorg prospects are generally good. Rabi prospects have been much improved in Bombay, and except in one or two districts the condition of the crops is generally good.

In the Berars, the Nizam's territories, and in the Central India and Rajpootana States, agricultural prospects remain unchanged.

The recent rain in the Punjab has much improved the rabi and the crops are now in excellent condition. In the North-Western Provinces and Oudh and in the Central Provinces, prospects are favourable.

More rain would be beneficial for the rabi in Bengal, which is however doing well; some of the crops are being gathered. The paddy harvest still continues, and the sowing of Boro paddy has commenced, and lands are being prepared in a few districts for the aus crops.

In Assam agricultural prospects continue favourable. In British Burmah the rice harvest has been almost completed, and threshing has begun, the outturn has been fair.

The public health is generally good. The mortality from cholera in the Chingleput, Coimbatore, Tanjore, Madura, and Malabar districts of Madras continues high.

Prices are falling in Bengal. Elsewhere they are generally stationary.

Madras.—General prospects fair, except in parts of Bellary and Anantapore.

Bombay.—Rain in parts of Sindh and Gujarat; rabi prospects greatly improved by the recent rain; standing crops generally in good condition except in parts of four talukas of Belgaum and three of Ahmednugger; scarcity of fodder and drinking water in several talukas of Dharwar and Belgaum; cholera in parts of Thana, Kanara, and Rutnagiri; fever in parts of 14, smallpox in parts of 9, and cattle-disease in parts of 7 districts.

Bengal.—There has been no rain again in any part of the province; rabi crops are generally doing well, but a shower of rain will greatly improve the prospects; some of the crops are being gathered; harvesting of paddy still continues; sowing of Boro paddy has commenced, and lands are being prepared in a few districts for aus crops; prices of food grains have been falling; cholera is abating in a few districts, but it is still prevalent in many others, and small-pox is reported from about half-a-dozen districts.

N.-W. Provinces and Oudh.—Weather cloudy, with light rain in most districts; destructive hail in Lucknow; prospects favourable, and prices easy.

Punjab.—Fever decreasing in the Hissar and Umballa districts; health of the rest of the province good; crop prospects good.

Central Provinces.—Weather still cloudy and rainy except in eastern districts; rabi prospects continue good; cattle-disease in Rajpore abating; prices steady.

British Burmah.—Cholera is somewhat prevalent in Prome and Thongwa; slight smallpox here and there, otherwise public health generally good; slight cattle-disease in Akyab, Bassein, and Thongwa; elsewhere health of cattle generally good; harvesting almost completed and threshing begun; outturn fair.

Assam.—Weather seasonable; mornings foggy, nights cool; harvesting of saki paddy over; sugarcane being cut; mustard doing fairly well; public health good.

Mysore and Coorg.—Crops in good condition in parts of Bangalore districts; poonji paddy has failed in Tumkooor district; Bengal grain is affected by worms; prospects fair; public health good, but cholera is prevalent in the Shimoga district.

Berars and Hyderabad.—Weather cool; jowari being reaped; prospects of rabi good; rabi sowings in progress; nosickao

Central India States.—Weather cloudy; prospects of crops and health good.

Rajpootana.—Weather cold and severe; crop prospects favourable; prices steady; health good.

Nepal.—Weather good; prospects fair.

Letters to the Editor.

THE ROYAL AGRICULTURAL COLLEGE AT CIRENCESTER.

TO THE EDITOR.

SIR,—I have just received a copy of the Cirencester local paper, giving the results of the last Diploma examination. You will see that Mr. D. B. Allen, B.C.S., has distinguished himself. As stated by the Principal, it was expected that Mr. Kee, and he would tie for the Gold medal, and that in fact the competition would have been much closer if Mr. Allen's studies had not been hindered by domestic bereavement. As it was, the Principal stated that under all the circumstances Mr. Allen's position was one which he hoped would be gratifying to himself, as it certainly was to the staff. He further reminded his hearers that in the last examination for the diploma of the Royal Agricultural Society of England, Mr. Allen had done honour to his college and to himself by occupying the first position of all the candidates.

Mr. Allen will be shortly back in India, and Bengal will have added another M. R. A. C. to its number. The first graduate of the College was Kumar Narayan of Cooch Behar. He was soon followed by Messrs. A. C. Sen, S. S. Hussein, and G. R. Bose, the last named having also secured first honours at the R.A.S.E. examination.

The failure of Mr. Chakravarti, who joined the college with Mr. Bose, will be learnt with much regret, and I can myself certify that that failure was due to ill-health alone. The class lists show a large number of Indian students. Besides the Bengal scholars, the names of Messrs. Hewson and Studman, of the Punjab Civil Service, and those of Messrs. Mehta and Sheshadre from Bombay, frequently occur in conspicuous positions.

E. C. OZANNE, M.R.A.C.,
Director of Agriculture, Bombay.

Editorial Notes.

THE Rhea Cultivation and Land Company, Limited, has been registered, the stated object being to cultivate reha, coffee, tea, &c., in India and elsewhere. The capital is only £10,000, divided into shares of £1 each. The first subscribers are—Charles Fox, clerk; S. J. Hewlett, clerk; Daniel Von Oegar, merchant; W. P. Daniel; Louis Francatelli, clerk; Messrs. Isaacs and R. W. Otto Roths. The Company is registered without articles of association.

.

SOME of the incidents in connection with the late hailstorm at Lucknow are interesting. At the Railway Workshops numerous flocks of pigeons have made the place a favourite haunt, and these were killed in large numbers by the hail, affording a cheap and extralicious of plump birds to many railway employes and their families. They were distributed in basketful among the occupants of the railway barracks. Great quantities of wild birds on all sides fell victims to the hailstorm. Those Bohemians of the Indian bird-tribes, the *crows*, especially suffered. Clever as they are in holding their own against mankind, all round, they were powerless to avert their fate when taken in flank,

and surprised as they were on Saturday morning. Every description of bird, in fact, having its *habitat* hereabouts, was to be found mangled and killed when the storm was over; the falling trees slaughtering them as effectually as the hailstones,—which, driven at hurricane-speed, must have had much the destructive effect of musketry at long range. The town lamps, too, have been extinguished since the storm. Many are of course injured, but others again are intact; nevertheless the lighting committee, or the lighting contractor, or whoever is in charge of this important function, have not been slow to grasp at the opportunity of economising the public kerosine, and so the roads are as dark as ever they were in Lucknow's darkest nights, when the old Municipal rushlights did duty as indicators of the surrounding blackness.

.

A MEMORIAL signed by 3,000 ryots of the Chingleput district in the Madras Presidency has been sent to the Government, praying for suspension of the collection of *kists* till February next, and to show them consideration in the remission during the *jummabundy* of this year. They also ask that orders be issued to the Revenue authorities to collect the instalments in future years after the month of January, when they will have harvested their crops, and will have converted their grain into money for the payment of Government dues. Their reasons for asking the concession is, that owing to the absence of rain in the proper season, they did not make good progress in agricultural operations this year. But owing to the fall of heavy rain in the latter part of the past year, they have incurred heavy loss in crops, and had to begin over the agricultural operations in many places. They also complain of the great hardship they experience in being compelled to pay the land *kist* every year from the month of December, even in years of favourable harvest, as they hardly harvest any crop at that time. Such being the case generally, their embarrassments have increased in the present season for reasons stated above. The occupation of the agricultural classes leaves no surplus fund to fall back upon in unfavourable seasons, so as to enable them to meet the Government demands in advance. Their annual receipt is barely sufficient to maintain them and their families throughout the year after paying the land-tax. In addition to these hardships, the land-tax which has hitherto been collected after the 15th of every month is now being rigorously enforced from the 10th, by order of the Revenue authorities. So far, justice seems to be on the side of the ryot; let us wait for the other side of the question—what the Government has to say for itself.

.

We have to thank the Indian Tea Association for copy of "Papers regarding the Sau Tree, and its remarkable influence on the Tea bush." In a little brochure of 16 pages, the subject is exhaustively treated without any attempt at so-called scientific investigations. It is a plain, unvarnished account of the experience of planters who have devoted their attention to this natural phenomenon. The Sau tree grows common in most parts of Assam, especially in land lying rather low. A planter in Upper Assam had some years ago drawn attention to it, and called it a "tea-fertilizing tree;" within the last few years, however, from experiments made, it has been proved that Sau tree possesses peculiar properties in considerably improving exhausted soils, thus causing tea bushes to flush vigorously, and imparting a vitality to old tea which it is sadly deficient in. Of course, in the absence of a thorough chemical analysis of the soil, it would be useless to hazard an opinion as to the reason of the Sau tree exercising such an influence, but that it does exist is a fact which may not be doubted since there is a consensus of opinion among the planters who have taken the trouble to watch the course of events. It is not on account of the shade it offers to the bushes, that the increase in yield can be explained away, because, as Mr. Buckingham says, "the generality of planters condemn shade. It tends to make the bush throw out long stalky shoots, racing with each other to reach the light, and the flushes from such trees are necessarily meagre and woody." But it is otherwise with the 'Sau.' The tea plants under this tree are broad in proportion to their height, have an even growth over the whole surface, and are equal to the very best tea found anywhere. But this is not all; the tea

under the 'Sau' enjoys immunity from blight when the surrounding trees are suffering. An area of three acres planted with 'Sau' about ten years ago has yielded for the last four years more than double as much tea as any other part of the garden. One planter accounts for the results thus:—"It is possible that Acacia trees take up nourishment from the soil not required by the tea plant, give sufficient, not too much shade, keep down jungle, and, sending their roots down much lower than the tea plant, drain the subsoil, and enable the latter to send roots down lower than it otherwise could."

.

CERTAIN South African economists are calling upon the farmers of the Cape Colony to make their own jam. It is pointed out, and not unreasonably, that the tradesmen of the Colony make a feature of their array of imported jams, but do not attempt to sell the home-made article; and the complaint is not unnaturally made that there is something wrong in the apathy of the people who in a country so well-favoured in the matter of fruit-production—where, indeed, the proposal has often been mooted that the surplus supplies of fruit should be exported, either fresh or dried, to Europe—actually import jams when they might make them better and cheaper themselves. No doubt, many households, as in England, make their own stock of "home-made" jams, instead of buying at all; but those who do buy have to put up with the imported article, simply, no doubt, because it has not occurred to any one to start *à la* Croasse & Blackwell. We have often urged agriculturists in the Colonies to "despise not the day of small things," and we are glad to see the warning re-echoed in the colonial press.

.

ANOTHER colonial product, the extended cultivation of which is being advocated in Cape Colony, is coffee. The *East London Advertiser* recently recorded the gathering of a crop of 2,000 lbs. of coffee from an experimental plantation near the Chalumna. This is by no means the first time that coffee has been grown in Cape Colony, but it is the first time, we believe, that so considerable a crop has been gathered on a single farm. It would make an interesting exhibit at the Colonial Exhibition in London in 1886—unless, indeed, by that time a better sample is forthcoming. Silk culture, again, is being urged on the attention of farmers in Cape Colony, just as in New Zealand. It is in new enterprises of this sort that the spirit of the Colony is ready to display itself, if only a period of rest from its internal troubles is guaranteed by a patriotic Government. Considerable attention, again, is being given to cotton planting, and seeds of different varieties are being distributed among the farmers of the Colony,—and even so far north as the Free States and Transvaal—by W. Cawood, of Grahamstown, for experimental purposes. Every effort to multiply the agricultural resources of our Colonies merits the warmest support.

.

MR. LUTTMAN-JOHNSON, Deputy Commissioner of Sylhet, has been enquiring into the subject of the prices of agricultural labour in his district. His calculation is based upon wages in kind paid to a reaper at harvest time. In twenty days' working at harvest time, a man might earn about six maunds of rice, enough to support him throughout the year. Reduced into money, the wages amount to five annas a day. In the report for 1882, similar results were shown in his account of wages paid in Sylhet for earth-cutting. Mr. Johnson says that natives of Sylhet will not work in tea gardens for two annas, the ordinary rate paid to tea coolies; but they have earned so much as five annas a day during the year under report. This is about as good a return for agricultural labour as may be found in any part of India.

.

THE agricultural and commercial depression now prevailing in England—on which Mr. S. Williamson, M. P., contributes a very able paper to the January number of the *Fortnightly Review*—may be said to have resolved itself into a fight of Charity against Starvation. Never was misery more severe, or helplessness more complete; never was the hand of the bountiful more liberal, or the organization for the relief of suffering more conscientiously developed. If the existing distress is not as widespread as that

created by the cotton famine twenty years ago, it is in many quarters as deep. In every town, from the East-end of London, throughout the Midlands, to far North of the Tweed, thousands and thousands of families are huddled in furnitureless rooms, hungry, cold, hopeless. On the Clyde, on Tyneside, at Jarrow, at Gateshead, at Aberdeen, at Glasgow, at Sunderland, at a hundred other centres of industry, men with large families to support have been unable to get work now for nearly twelve months, and it says much for the thrift of the working classes that many have until quite recently staved off the hour, when an appeal to charity became inevitable, solely by their hard-earned savings. What the condition of the country would be at this moment, but for its Charitable Organisations, it is impossible to conceive. At places like Jarrow thousands of children are fed and families relieved out of the funds of the Local Committee; in Newcastle a thousand pounds a month goes in relief; in Sunderland over seven thousand pounds has been raised for similar purposes. And these are only a few instances of the noble efforts which charity is making to withstand the starvation of the masses.

.

The Collector of Bellary lately reported that the circumstances of the district render it improbable that an Agricultural Exhibition held at Gooty during the present season could result in anything but failure. Farmers are thoroughly discouraged by the drought of the present year, which in Gooty, Alur, and Bellary taluks, is certainly the severest of which there is any record, or tradition. With much regret, therefore, he recommended that the idea of holding the show next month be given up. The Government has therefore postponed the show for one year.

.

The report on the prospects of the wheat crop in the North-Western Provinces and Oudh, for the month of December, is as follows:—"The estimated area under pure wheat in the North-Western Provinces and Oudh, according to the returns of December, is 5,532,200 acres against 5,523,500 acres estimated in November. The increase of 8,700 acres is due to the sowings not having been quite finished when the November forecast was issued. Slight and partial showers of rain fell in the northern and western districts late in December, but not sufficient for the young crop. Little or no rain fell in the southern and eastern districts. Owing to the almost complete failure of the December rains, the hopes expressed in the November forecast of a bumper crop cannot be realised. But if moderate rain falls in January, the crop will still be above average. If no rain falls in January, a serious deficiency may be anticipated."

.

The last Administration Report of British Burmah tells us that nearly ninety per cent (88) of the cultivated area in the province, is under paddy, the cultivation increasing steadily by more than 100,000 acres a year. Out of the 4,000,000 acres under tillage, 232,428 acres are fruit and vegetable gardens. "This kind of agriculture pays well, and that a ready market exists for all orchard and garden produce goes to support the view that the people of British Burmah are well off, and live comfortably." We have frequently pointed out that the calculations of our settlement officers are constantly vitiated, by their uniform failure to take any account of the garden, fruit, and dairy produce of the ryot's holding. Whenever these holdings are in the neighbourhood of the cities which are growing up all over India, these items form a most valuable part of the produce, as we here read they do in Burmah. The report tells us that in most parts of the province, the land revenue amounts "to from one-twelfth to one-tenth of the value of the gross produce, and good markets are available directly the rice crop is harvested."

The exports from the province are about £9,000,000 sterling a year, the chief items being—

Rice (paddy)	£ 5,500,000
Cutch and Gambia	370,000
Hides	100,000
Timber	1,600,000
Cotton	200,000

The gross land revenue is about £670,000 a year, but the addition thereto of a capitation tax of £300,000 a year; brings the assessments up to nearly £1,000,000 sterling. The general result is that the land bears an assessment of about two

rupees and-a-half per acre, the State thus exacting a larger payment from the cultivator, than the so-called rack-rent levied by the zemindar in these provinces under the Permanent Settlement. When we remember the resources of the two provinces, and the fact that more than 88 per cent in Burmah is simply under paddy, we have another forcible illustration of the absurdity of supposing that a rental of less than Rs. 2 per acre in Bengal, with its richly varied produce, can possibly be a rack-rent. We cannot push our inquiries in any direction whatever, without seeing how absolute are the delusions under which the Tenancy Bill has been brought into Council. The Government may persevere with it, if it chuses to do so, but it is in the teeth of a general conviction that it ought not to do so.

.

It is seldom we get so exact a statistical fact as the official statement that "88.5 per cent of the cultivated area of British Burmah is under paddy, assessed at an average of Re. 1-14-5 per acre." Now this *assessment* is as nearly as possible the precise sum per acre which the Bengal zemindar exacts as rent from his tenants in these provinces, and that the framers of the Rent Bill persuaded themselves was a rack-rent. The exact area of land under *paddy* in the Bengal provinces is unknown, but we do know that paddy is the least valuable crop which the ryot grows. With nothing but paddy in Burmah, the State exacts an assessment of precisely the same weight as the rental charged by the zemindar upon the richly productive soil of these provinces. And he is an oppressor! But the State exaction is a good deal heavier in Burmah, for every adult married man in Burmah has to pay a capitation tax of Rs. 5 a year in addition to the assessment, so that if his holding is five acres, he has to pay Re. 1 per acre in addition to the Re. 1-14-5, or nearly Rs. 3 per acre.

In the North-West Provinces, as we have seen, the assessment alone is Rs. 3 per acre, and the rental Rs. 3 more. Is it possible we ask, for proof to be more overwhelming, than the proof these simple facts furnish, of the astonishing ignorance under which the Bill was drafted? And is it creditable we ask, for the Government to persevere with a measure based upon such astounding misconceptions? For the State to exact Rs. 3 per acre from mere paddy cultivation in Burmah, and Rs. 3 per acre from the comparatively sterile soil of the North-West Provinces, is nothing, but for the zemindar to exact less than Rs. 2 per acre from the rich deltaic soil of these provinces, is so oppressive that we must positively cancel the Settlement made with him, on the ground of the extortion he is practising upon his tenants!

.

The second report on the prospects of the wheat crop in the Central Provinces is as follows:—"Rain has fallen throughout the Provinces, but has fallen unequally. In the last week of December, there was a fall ranging, roughly speaking, from 2 inches in southern to half inch in northern districts. Since then more rain has fallen in the north of the Provinces, and the wheat prospects of the northern districts may be considered assured; in the Southern districts of Chhattisgarh and the Nagpore country, prospects are excellent, and were it not for the contraction in area, the gross outturn would be above the average."

.

The following is Captain Plumer's report on the Mysore Gold Co., dated 13th November:—"In Taylor's shaft, under the 173 on the underlie, we have been taking down broken rock from the hanging side, and putting in timber this week. Width of lode 3 ft.; assay value, 5 ozs. 4 dwts. 8 gra. of gold per ton. In the north drift the lode is smaller (18 in. wide). There is a great deal of water in the No. 1 winze in bottom of the 173 on west lode; the little rib of quartz I reported has cut out. No. 2 winze, in bottom of the 173 on west lode; there is some difficulty in getting men to work these hard places; we hope to do better next week. In the 173 north end on west lode the rock is very tight, a mixture of quartz and trap-rock. The 173 north end back to the point under the proposed new shaft; it will help this work greatly. We are melting gold to-day, but I am not sure that it will be completed in time for me to give you the full information in this letter."

It will far surpass any of our previous returns. It has been an exceptional month, as we got to the bottom of the old men's works and had the rich pickings they left behind. Now we have to sink, and in the hard stone progress is slow."

.

As the French Government has now made known the amount of duty which it will consent to lay on foreign corn, it is of general interest (says a correspondent of the *Standard*) to establish by a comparison with other countries the position France will be in if the Chambers adopt and ratify the proposals of the Cabinet. These proposals are that a duty of 2fr. 60c. shall be levied on every 100 kilogrammes of corn imported into France, and that the tax on the same quantity of flour shall be 5fr. 20c. There are six European countries, England, Belgium, Denmark, Sweden, the Netherlands, and Russia, in which corn does not pay any import duty at all. In the other European States the import duty on corn and flour expressed in francs and centimes, and per 100 kilogrammes, is—Switzerland, corn 30c., flour 1fr.; Norway, corn 28c., flour 1fr. 71c.; Italy, corn 1fr. 40c., flour 2fr. 77c.; Germany, corn 1fr. 25c., flour 3fr. 75c.; Austria-Hungary, corn 1fr. 25c., flour 3fr. 75c.; Greece, corn 1fr. 41c., flour 3fr. 51c.; Spain, corn 4fr. 20c., flour 6fr.; Portugal, corn 5fr. 60c., flour 8fr. 96c.; Turkey, corn 8fr. 10c., flour 8 per cent. It therefore follows that if, instead of maintaining the existing import duty of 60c. on corn and 1fr. 2c. on flour, the Chambers vote the Government proposals, and raise it to 2fr. 60c. on corn and 5fr. 20c. on flour, bread will not only be dearer in France than in England, Belgium, Denmark, Sweden, the Netherlands, and Russia—where no import duty is levied on corn—but also dearer than in Switzerland, Norway, Italy, Germany, Austria, and Greece, where the duty would be lower. At the present moment, when such undeniable distress prevails among the poorer classes, it is almost impossible to exaggerate the consequences of that increased taxation, for the burden of the tax would fall chiefly on the French workmen, who make bread their chief article of food. It is calculated that the proposed augmentation on the duties on corn and flour would entail the additional expenditure of 60fr. per annum for a workman's family composed of four persons. Of course the partisans of this protectionist measure pretend that the working classes would be compensated for the extra expenditure by higher wages, but all the evidence that has been collected by the Parliamentary Committee instituted to inquire into the present economic crisis, goes to prove one of its chief causes to be the price of labour in France, which is already so high that French manufacturers cannot compete with their foreign rivals.

.

The report on the prospects of the wheat crop in the Berars for the month of December is as follows:—"Acreage under wheat 845,136; 5 per cent above the average, which is 803,055 acres for the province. Crops in good condition, but fears are entertained of possible damage from excessive cold after unusually heavy rain."

.

The *Mining Journal* of the 13th ultimo wrote: "Mr. Justice Chitty has directed a meeting of the creditors of the Mysore Reefs Gold Mining Company to be summoned for Friday next, to ascertain their wishes as to the proposed sale of the mining property, plant, and machinery of the Company, upon the terms set forth in an agreement dated December 5, and made between the Company of the first part, Thomas Stephen Evans of the second part, and J. Harvey, C. J. Harvey, L. H. Evans, C. S. Blair, and J. Cockburn of the third part, as trustees for a new Company intended to be formed and registered as the New Mysore Reefs Gold Mining Company (Limited). The said judge has appointed the said Thomas Stephen Evans, the official liquidator of the said Company, to act as Chairman of such meeting. The terms of the intended sale, are—1. The payment of £5,500 by instalments extending over nine months.—2. The intended Company undertaking, in the first instance, to offer its shares to all the Mysore Reefs shareholders, *pro rata*, according to their respective holdings. Such shares are to be applied for (if the present Mysore Reefs shareholders desire to have them at the price) within a period

to be fixed by the Directors of the new Company, and to have the sum of 15s. per share credited as paid thereon, and the balance of 5s. payable upon such shares to be paid by instalments, and they are also to be offered by the Directors of the said new Company one fully paid £1 share in the new Company as a bonus upon every five shares that shall be subscribed for such bonus share, to be allotted when the other shares shall be fully paid up, the new Company to take all necessary steps to register an agreement for the issue of such share with the Registrar of Joint-Stock Companies."

.

The first report on the prospects of the wheat crop in the Punjab is as follows:—"Average acreage 6.75 millions, estimated actual 7.25 millions; estimated outturn two million tons; no real returns are available, but sowings are above average, and prospects excellent."

.

The following extract from the Annual Administration Report of the Department of Horse-breeding Operations for the official year 1883-84 will be found interesting. The Assistant Superintendent reports as follows:—"On the whole my tour was a successful one; but in the Etah, Agra, Bareilly, Moradabad, Bijnor, and Badam districts I regret to say that I found horse-breeding at a stand-still. On the other hand, the Saharunpore, Mozuffernugger, Meerut, Boolundshahr, and Aligarh districts are progressing favourably, particularly so Saharunpore, Mozuffernugger and Boolundshahr, which are at present most flourishing districts for horse and mule-breeding in the provinces."

.

A very interesting monograph on the cotton manufacture in the Punjab has just been issued by Mr. Francis. From this it appears that the export of cotton beyond the frontiers of the province is very small indeed, and 84 per cent of the entire, annual yield is used up locally. It is a peculiarity among the Punjabi women, of all classes, whether high or low, rich or poor, to spend their leisure hour in spinning; and where it is the pride of a good house-wife to weave all the clothing that her family require. It is therefore not a matter for surprise that very little of the raw material, which is in such great demand should find its way out of the country. The average annual exports from the year 1880-81 to 1883-84 were 137,344 maunds, out of a total of 1,011,815 maunds annually. The Punjab cotton has a tough fibre, much shorter than that of the American varieties; and even acclimatized American cotton, except under specially favourable circumstances, shows a marked tendency to shorten also. As an indication of the general prosperity of the land of the Five Rivers, it may be said, that rather more than five hundred lakhs of rupees are spent annually by the people on cotton fabrics—an improved condition in the material well-being of the country, which any other province can hardly show. Of course the supply of native material cannot keep pace with the demand, and is insufficient to meet so large an outlay. European goods therefore are largely and increasingly imported, more than three hundred and fifty thousand maunds of European cotton goods find their way to the Punjab; and the greater portion of the Kohat *lungis* and scarves are woven from Manchester yarns. In connection with these figures, Mr. Francis remarks:—"It seems probable that notwithstanding the competition of Manchester, the Punjabi weaver's trade is rather extending than diminishing, and that there is still plenty of room for both."

.

Mr. H. W. Foster, Acting Head Assistant Collector of Tanjore, has reported that an extraordinarily heavy rain-fall was experienced throughout his division in November, from noon of the 3rd to noon of the 4th. At Negapatam, on the coast, 8.70 inches was recorded, while at each of the stations, Tiruvalur and Nannilam, fifteen miles inland, the unprecedented figure of 21 inches was reached. At Kodavaal, about another 15 miles to the west, 7.30 inches was registered, so that it would seem that the storm reached its culmination on the line joining Tiruvalur with Nannilam, eight miles due north. The gauges at both these places are placed on small pillars, and well isolated from

trees and buildings, so that there is no reason to suppose that the apparent rain-fall has been magnified by splashing off the ground or drippings from roofs or trees, while the coincidence in the figures at two stations so far apart precludes the supposition that there has been error in measurement. At both stations also the rain-fall had been measured in the two preceding days, so that the previous day's rain cannot have been included. Mr. J. B. Pennington, the Collector of Tanjore, adds, that the heaviest falls on the same day, in other divisions, were $10\frac{1}{2}$ inches at Shiyali, 10 at Mayavaram, 9 at Tranquebar, and 8.32 at Kumbakonam; and the total rain-fall up to the 14th of this month was almost the same for Shiyali and Tiruvalur, viz., $34\frac{1}{2}$ inches, or at the rate of nearly $2\frac{1}{2}$ inches a day for a fortnight.

**

ACCORDING to a contemporary the fortnightly returns of prices current, published in the *Punjab Gazette*, show clearly how different the condition of the districts in the south-east of the Province is now, from what it was a year ago. *Joar*, which was then selling at a rate of 24 seers per rupee, in Gurgaon and Rohtak, now sells at 40 and 35 seers per rupee; and *Bajra*, which then sold at 21 seers in Gurgaon and Hissar, now sells at 40 seers and 33 seers. Similarly, the price of gram in Gurgaon has fallen from 23 to 28 seers, and the price of barley from 27 to 36 seers; and though the selling prices of these grains are higher in the adjoining districts of Hissar and Rohtak, they are nevertheless very much more favourable than they were twelve months ago. The curious variations of agricultural prosperity which a district may undergo in the Punjab, can be judged from the fact that, whereas the prices of the common millets were higher in Gurgaon, during the second fortnight in December 1883, than in any other district of the Province, they are now lower than those anywhere else, except in the old Rawalpindi Division and Sialkote. The state of the supplies of the market in this part of the Punjab may be imagined, when we say that barley is selling at a rate varying from 46 to 58 seers per rupee, and wheat from 29 to 33 seers. If the present winter rains should prove favourable, Punjab prices are likely to reach an unprecedentedly low point during 1885-86.

**

THE following is the official summary of the Bombay Presidency season reports for the week ending January 14:—
"Rain in parts of Sind and Gujarat; rabi prospects generally in good condition, except in parts of four talukas of Belgaum and three of Ahmednugger. Scarcity of fodder and drinking water in several talukas of Dharwar and Belgaum. Cholera in parts of Tanna, Kanara, and Rutnagherry; fever in parts of fourteen, small-pox in parts of nine, and cattle-disease in parts of seven districts."

**

MR. C. A. COLLIN, Collector of Anantapore, writing on the 7th November, says "that the north-west monsoon has proved a failure in this part of the district, and looking to the statistics of previous years, there is but little prospect of any change in the season at this late date, which would materially alter the present state of affairs. I enclose a statement showing the rain-fall during the current year, up to date, at Gooty, as compared with the last ten years. The rain-fall to date is but little in excess of that registered in the famine year 1876. It will be seen that both the north-east and south-west monsoons have been very scanty, as was the case with the last north-east monsoon also; there have thus been three successive failures. The tanks in this division are consequently absolutely dry, and in the town of Gooty several of the wells are in the same state, and the supply of drinking-water at present hardly suffices for the wants of the inhabitants. The condition of things will be worse when the hot weather sets in, and I fear that there is but little prospect of any material addition to the supply. The dry crops, moreover, have failed, and fodder is very scarce; the cattle have even thus early been driven in large numbers to the hills in the Kurnool district for pasturage, and as comparatively little dry land has been sown during the present monsoon, no great addition to the present supply of straw is to be looked for. Owing to the tanks being dry, the wet lands have been left waste. There will consequently be great difficulty in procuring water and fodder at the time fixed for the exhibition; a large

gathering will only tend to increase this difficulty, and owing to the very unpropitious nature of recent seasons, the exhibits from this district would necessarily be few and poor. I understand that the season has been equally unfavorable throughout a large portion of the Bellary district, so that two, at least, of the four districts, for the benefit of which the exhibition is specially intended, are not likely to be adequately represented. The Government, in the season telegram, for the week ending 3rd instant, says, with regard to Bellary: Standing crops, dry and wet, withering from want of rain. Harvest—paddy and dry grains, yield below average. . . . General prospects—fair, except in parts of Bellary and Anantapore, where they continue unfavorable."

**

FROM a report on the external trade of Bengal with Nepal, Sikkim and Bhootan, for the year 1883-84, it appears that the total value of the traffic registered during the past official year, on all the important trade routes at 32 stations along the frontier between Chumparun and Julpigoree was as follows:—Of imports into Bengal, Rs. 74,94,083; of exports from Bengal, Rs. 66,92,641. Besides these figures the total value of traffic with other provinces which passed over Bengal was as follows:—Of imports from Nepal, Rs. 1,28,423; of exports to Nepal Rs. 5,56,118; total value of traffic registered amounted to Rs. 1,48,71,315; the gross value of the trade during 1883-84 was 2.44 per cent in excess of figures of the preceding year, and 2.12 per cent over those of 1881-82. The import trade, however, shows a material falling off, the figures for the past year being 8.46 and 7.84 per cent below those of the two previous years respectively. Under exports, there was an increase of 17.11 per cent, as compared with 1882-83, and of 15.21 per cent, as compared with 1881-82. The chief staples in the import traffic which showed the largest decrease during the past year, as compared with 1882-83, were food-grains, timber, and silver; and the articles showing the largest increase were precious stones and pearls (unset), cattle, opium, linseed, and saltpetre. As regards exports, the greatest improvement is found in European piece-goods, metals, provisions, treasure, horses, salt, tobacco, and unrefined sugar, while manufactured woollen goods showed a decrease. To descend to details the total value of the trade of Bengal with Nepal registered during the year 1883-84 was Rs. 1,36,30,623.

**

THE gross value of the trade shows an increase of 3.93 and 4.23 per cent, as compared with the totals of the years 1882-83 and 1881-82, respectively. Under imports there is a decrease of 5.07 and 4.85 per cent, but as regards the exports, the figures indicate an increase of 16.18 and 16.62 per cent. The chief staples which show an improvement over the trade of the previous year, are cotton piece-goods (Rs. 4,06,019), precious stones and pearls, unset, (Rs. 3,57,731), miscellaneous rain crops (47,273 maunds), linseed (41,313 maunds), salt (18,330 maunds) provisions other than ghee (13,383 maunds), tobacco (10,406 maunds), saltpetre (8,647 maunds), iron (7,651 maunds), brass and copper (7,426 maunds), undrained sugar (6,921 maunds) and opium (238 maunds); and the articles in which the largest decrease occurred are rice (3,21,755 maunds), paddy (1,13,670 maunds), miscellaneous spring crops (20,909 maunds), timber (1,82,841 maunds), mustard seed (18,113 maunds), hides (11,953 pieces), skins of sheep, &c. (17,478 pieces), and woollen goods (Rs. 67,630).

**

THE cattle trade showed an increase of 6,953 head as compared with 1882-83, and of 2,355 head as compared with 1881-82. The figures under imports are 25,277, of which 8,041 were sent into Chumparun, 7,635 into Mezufferpore, 5,972 into Purneah, and the remainder, 3,629, into other districts. The cotton, raw, trade during the year in this staple was 8,862 maunds against 9,767 maunds in 1882-83, and 7,494 maunds in 1881-82. The total quantity exported to Nepal was 8,069 maunds, of which 6,741 maunds were drawn from Chumparun, 521 maunds from Purneah, and the rest from the other frontier districts of Behar. The traffic in European piece-goods showed a great improvement. The total value of the different sorts of these goods exported to Nepal during the year was Rs. 21,35,246, being Rs. 3,15,654 in excess of the figures of 1882-83, and

Rs. 3,00,428 in excess of those of 1881-82. In the case of Indian piece-goods, the exports showed an increase of Rs. 69,491 and Rs. 14,856 as compared with the figures of 1882-83 and 1881-82, respectively. There was a considerable falling off in the import trade in food grains during the past year, the total quantity amounting to 15,45,390 maunds against 19,48,355 maunds in 1882-83, and 16,77,657 maunds in 1881-82. The Collector of Chumparun writes—"Owing to the shortness of the *aughani* harvest and disturbances with Tibet, the export grain from Nepal was stopped for some time. A *chunpati mahajun*, who cultivates land in Nepal, complained to the sub-divisional officer of Bettiah that he was not allowed to export his own grain." The figures of the import traffic in hides for the past year show a decrease of 11,957 pieces as compared with 1882-83, but an increase of 20,802 pieces as compared with 1881-82.

.

THE total imports under the head of skins of sheep, goats and other small animals, amounted to 50,275 pieces against 67,454 pieces in 1882-83, and 47,709 pieces in 1881-82; out of the year's imports, 44,466 pieces were registered at Bairagnia in the Mozufferpore district. The trade in brass and copper, and in their manufactures is steadily increasing. The quantity exported to Nepal during the year was 19,541 maunds, valued at Rs. 7,81,640, against 12,323 maunds, valued at Rs. 4,92,920, in 1882-83, and 8,707 maunds, valued at Rs. 3,48,280, in 1881-82. Of the year's supply, 16,253 maunds were exported *via* the Chumparun district. The import trade in ghee showed a decrease of 3,113 maunds on the returns of 1882-83, and an increase of 1,358 maunds as compared with 1881-82. The total traffic in all other kinds of provisions amounted to 79,193 maunds against 65,810 maunds in 1882-83, and 1,01,037 maunds in 1881-82. As compared with 1882-83, the import trade showed an increase of 2,065 maunds, and the export trade of 11,318 maunds. The great bulk of the imports was registered on the frontier of the Purneah district, but as regards the exports, the largest supply, amounting to 26,547 maunds, was sent to Nepal through Chumparun; Purneah exported 12,066 maunds, and other stations 5,598 maunds. The large increase in the amount of salt carried to Nepal is specially noticeable, the total quantity being 97,427 maunds against 79,260 maunds in 1882-83, and 81,450 maunds in 1881-82. There was a great recovery in the import trade in saltpetre, the total quantity having amounted to 14,521 maunds against 5,985 maunds in 1882-83, and 12,911 maunds in 1881-82. The principal districts to which saltpetre was consigned in large quantities were Mozufferpore (7,525 maunds), Durbhunga (4,297 maunds) and Chumparun (2,699 maunds). The total quantity of linseed imported into British territory was 41,341 maunds in excess of the imports of 1882-83, and 1,09,778 maunds over those of 1881-82, but under mustard seed, the figures fell off from 81,373 maunds in 1881-82, to 71,150 maunds in 1882-83, and 52,802 maunds in 1883-84.

THE value of manufactured silk exported to Nepal was Rs. 98,383 against Rs. 1,12,867 in 1882-83, and Rs. 52,555 in 1881-82. The statistics of the frontier post of Kutkenwa in Chumparun show that as much as Rs. 81,000 worth of the goods exported during the year were sent to Nepal by that route. The total quantity of drained sugar sent to Nepal was 7,785 maunds against 4,975 maunds in 1882-83, and 6,314 maunds in 1881-82, while the supply of undrained sugar rose from 20,429 maunds in 1881-82 to 20,869 maunds in 1882-83, and 27,786 maunds in 1883-84. Of the exporting districts Chumparun contributed 3,933 maunds of drained and 11,035 maunds of undrained sugar; Mozufferpore 1,145 maunds of drained and 3,887 maunds of undrained sugar, and Durbhunga 637 maunds of drained and 6,069 maunds of undrained sugar. The total weight of tobacco registered was 40,004 maunds against 29,598 maunds in 1882-83, and 29,787 maunds in 1881-82. The increase in the import trade was 3,891 maunds as compared with the previous year, and in the export trade 6,515 maunds. Of the importing districts, Purneah received 3,612 maunds, Mozufferpore 2,686 maunds, and Durbhunga 1,192 maunds, while as regards the exports, the largest supply was sent from Mozufferpore (13,360 maunds) and Chumparun

(13,018 maunds). The timber trade showed a falling off of 1,83,841 maunds as compared with 1882-83, and of 76,083 maunds as compared with 1881-82. The total value of the export trade in wool, manufactured, of the past year, showed a decrease of Rs. 67,909 as compared with 1882-83, but it exceeded the figures of 1881-82 by Rs. 51,614. The great bulk of these supplies was carried to Nepal by the routes passing through the Chumparun district.

.

THE total value of the trade between Bengal and Sikkim registered during the past year 1883-84 was—imports from Sikkim, Rs. 2,21,523; exports to Sikkim Rs. 1,12,711: total, Rs. 3,34,234. The advance in the aggregate value of goods registered was Rs. 17,792, or 5.62 per cent as compared with the previous year, and Rs. 80,690 or 31.82 per cent as compared with 1881-82. The improvement was mainly in the import trade, the most noticeable items which contributed to the increase in the year's traffic as compared with 1882-83 being raw wool, miscellaneous rain crops, foreign tea, horses, provisions, spices, gram, and shell-lac. The export trade, however, would appear from the returns to have remained almost stationary, a falling off being shown in the traffic in indigo, cotton piece-goods (European), other metals, cattle and iron, and an increase appearing under tobacco, woollen goods, paints and colours, cotton piece-goods (Indian), brass, provisions, oils, and dyeing materials. The imports of hill ponies through Pheydong showed a small increase during the past year, the total number being 683 against 662 in 1882-83, and 636 in 1881-82. The recorded cattle trade fell off by 65 head as compared with the previous year, and by 26 as compared with 1881-82. There was a decrease of 23.26 per cent under sheep and goats on the returns of 1882-83, but an increase of 17.46 per cent is shown on comparison with those of 1881-82. The figures under lime and limestone showed a great improvement during the year, the total quantity being 6,051 maunds against 1,897 maunds in 1882-83, and 3,179 maunds in 1881-82. The supply of miscellaneous rain crops is steadily increasing, the total quantity during the year showing an advance of 4,009 maunds on the trade of 1882-83, and of 10,597 maunds on that of 1881-82. This is all registered at Rungeet.

.

THE number of hides registered was 751 pieces against 760 pieces in 1882-83, and only 106 pieces in 1881-82. The quantity of shell-lac rose from 2 maunds in 1881-82 to 9 maunds in 1882-83, and 19 maunds in 1883-84. Brass and copper showed a decrease of 90 maunds as compared with the total of the previous year, and of 343 maunds on the figures for 1881-82. The amount of ghee registered was 96 maunds against 141 maunds in 1882-83, and 111 maunds in 1881-82. All other kinds of provisions, however, showed an increase, the figures for the past year amounting to 71 maunds against 34 maunds in 1882-83. The quantity of untaxed foreign salt fell off from 1,779 maunds in 1881-82 to 791 maunds in 1882-83 and 606 maunds in 1883-84. It is believed that a further decrease will take place, if indeed the import of this article is not entirely extinguished, as recent enquiries have shown that duty-paying salt is consumed at places in Sikkim four marches from Darjeeling. The traffic in spices was active, the quantity imported being 239 maunds against 159 maunds in 1882-83 and 119 maunds in 1881-82. The quantity of the brick tea of Tibet imported during the year was 77 maunds against 42 maunds in 1882-83, and 64 maunds in 1881-82. The Deputy Commissioner of Darjeeling has recently received a few samples of tea manufactured after this method in British territory by Messrs. Cresswell and Company, and he has been directed by the Government of Bengal to facilitate its sale in those markets of his district which are most frequented by Thibetan traders. An allotment of Rs. 100 has been sanctioned for the purpose of paying commission to the shop-keepers who may be entrusted with the sale of the tea.

.

In the last report it was pointed out that one of the most satisfactory features in the trade of that year was the beginning of a steady import of wool, of which there is an unlimited supply of excellent quality within a few days' journey from

Darjeeling. The result of the registration during 1883-84 shows that so much as 911 maunds of this article were sent into British territory against only 168 maunds in the preceding year, while in 1881-82 no traffic was returned under this head. It is believed, however, that the wool trade has dwindled during the current year, partly owing to the difficulties placed in the way of traders by the Tibetan frontier officials. There was a slight decrease in the value of manufactured woollen goods (chiefly blankets), but the figures are still in advance of those of 1881-82 by Rs. 13,231. The imports, under "all other articles of merchandise, manufactured," showed an increase of over 111 and 154 per cent on the figures of the preceding two years.

.

THERE was a slight decrease of 5.77 per cent in value of piece-goods registered as exported during the past year as compared with 1882-83, but when compared with the figures of 1881-82, a large increase of 46.54 per cent is observed. Similarly indigo shows a falling off of 44 maunds on the returns of the previous year, and an increase of 35 maunds on those of 1881-82. The exports of miscellaneous dyeing materials rose from 26 maunds in 1881-82 to 70 maunds in 1882-83, and 85 maunds in 1883-84. The aggregate total of metals registered as exported was 408 maunds, showing a decrease of 154 maunds on the returns of 1882-83, and an increase of 143 maunds on those of 1881-82. The exports of silk rose during the year to 110 maunds against 61 maunds in 1882-83, and 3 maunds in 1881-82. The advance under paints and colours was 21 maunds, and in provisions 38 maunds as compared with the previous year. The total quantity of salt was 392 maunds against 265 maunds in 1882-83, and 173 maunds in 1881-82. There has been a considerable increase under tobacco, the exports registered during the year amounting to 2,331 maunds against 1,487 maunds in 1882-83, and 709 maunds in 1881-82.

.

THE figures given in the registers have been quoted above, but it has been ascertained that they are quite unreliable. This subject has recently been carefully investigated by reference to the railway records and by enquiry among persons in whose house Tibetan traders at Darjeeling and Jore Bungalow are known to have resided. Such an enquiry must necessarily be incomplete, but it has elicited information which shows that the present system of registration is inefficient. The difference is Rs. 1,46,725. The registers show the value of English piece-goods exported by Pheydong as Rs. 27,940. Enquiries among certain merchants show that piece-goods to the value Rs. 27,200 were despatched to Pheydong from Kalimpong, and that goods to the value of Rs. 28,500 were sent from Darjeeling to Kalimpong, for export. The total is Rs. 55,700. Endeavours are now being made to place the system of registration of Sikkim and Tibetan trade on a more satisfactory footing. It is probable that the trade is not less than double the amount now registered, and when it is considered that it has so many difficulties to contend with, through the obstructiveness of frontier officials and the exclusion of Indian merchants, it may be inferred that a large expansion of the trade would follow upon the removal of the obstacles by which it is now impeded. A special report on this subject is under submission.

.

THE trade between Bengal and Bhootan was, as usual, intercepted at Ambaree, Hantoopara, and Buxa in the Julpigoree district. The first two stations were kept open for five months, and the third station for ten months of the year. The total value of the trade registered during the past year 1883-84 was—imports from Bhootan, Rs. 96,350; exports to Bhootan, Rs. 1,23,000; total, Rs. 2,19,350. It will be observed that the gross value of trade during the past year was 10.70 per cent in excess of the previous year's figures. The value of imports, however, decreased by 13.54 per cent, while that of exports increased by 41.88 per cent. As regards the imports, the decrease is observable in almost all articles of traffic, notably in tobacco, European piece-goods, rice, betel-nuts, and unrefined sugar. As compared with 1882-83 the falling off in the import of horses was very large, namely, 267, valued at Rs. 20,035. The trade in madder or manjit, on the other hand, was exceedingly active, the increase in the quantity imported being 437

maunds or 590.54 per cent. Vegetables, fruits, and nuts showed an increase of 729 maunds, but ghee showed a decrease of 64 maunds. The figures under foreign tea, however, showed a decrease of 24 maunds. The value of manufactured woollen goods (chiefly blankets) showed an advance of Rs. 1,846. The large decrease of Rs. 3,244 in the value of "all other articles of merchandise manufactured" was due to the falling off in the imports of wax, of which only 21 maunds were registered at Ambaree against 137 maunds in the previous year; on the other hand, the advance of Rs. 4,301 in the value of "all other articles of merchandise unmanufactured" was owing to an increase in the imports of musk and yaks' tails. The total value of the former amounted to Rs. 5,913 against Rs. 2,491 in the previous year, and of the latter to Rs. 1,860 against Rs. 638 in 1882-83. The trade in European piece-goods exceeded that of 1882-83 by Rs. 4,573. Twist and indigo were for the first time exported to Bhootan during 1883-84 *via* Buxa and Ambaree. The exports of rice showed an advance of 2,197 maunds. The quantity of metals fell off from 295 maunds in 1882-83 to 179 maunds in 1883-84. The salt trade showed a decrease of 122 maunds. In manufactured silk goods there was an advance of 46.31 per cent, as compared with the previous year. The exports of betel-nuts were 2,958 maunds against 2,158 maunds in 1882-83. The rise in tobacco from 3,284 maunds in 1882-83 to 4,783 maunds in 1883-84, is specially noticeable.

.

On the 6th of December 1884, the Collector of Coimbatore reported to the Director of Revenue Settlement and Agriculture, Madras, that he was "apprehensive that the proposed show at Erode will not be a good one, and am inclined to think it will be best to put it off. The season has been a very bad one. The crops being out of the usual season will not, it is anticipated, be nearly as good or as fine as usual. The cattle have had a bad time of it; starved at first in the drought, they are now unhealthy from the profusion of green food. The people are calling out for remission, and are generally out of humour with things. As it is the first show of the kind for some time, it seems a pity it should not be as good as possible. I apprehend that the districts from which exhibits may be expected are not in a better state than this." The recommendation of the Director of Revenue Settlement and Agriculture has been approved by the Government of Madras, and the Erode exhibition has been postponed till the early part of January 1886.

Review.

TEA-PLANTING IN CEYLON.*

I.

"TEA-PLANTING in Ceylon, and other items," is the title of a work, written evidently by a planter, under the *nom de plume* of "Eastward Ho." His object, as set forth in the preface, is to advance the interests of Ceylon, "by calling attention to the unequalled field for enterprise now open here, at a time when fresh blood and capital is alone the great need." But at the same time, while compiling the book, his thoughts have turned to the colonies; feeling certain, as he says, "from as careful a study of the characteristics of the climate and soil, as extant accounts at command have permitted, that, in the indicated localities, the products, as named, will be found to succeed admirably, and not impossibly, become the means of converting into highly profitable property large areas of now waste lands." In treating of "Coffee," he warns future planters against procuring supplies of seed from the produce of either Java, India, or Ceylon trees, or of any other country where the plants suffer from what is known as leaf disease. To this cause he attributes, not only a partial failure, but the utter ruin of the enterprise in Fiji, the Seychelles Islands, and the Straits Settlements. The best plan, therefore, is to use the seed brought from a country where the plants are not affected by the disease. In the opinion of our author, the "Blue Mountain" coffee of Jamaica has a good name, and commands a high price

* Tea Planting in Ceylon with other items. By "Eastward Ho." Colombo: Printed at the "Times of Ceylon" Press.

in the home market. But he yields the palm to the two varieties (probably identical) in Brazil, called the "the Visconde de Jaguar," and "Margopipe," which he thinks will galvanize the enterprise everywhere. Their superiority seems to be universally acknowledged, for the Brazilians themselves are absolutely rooting out whole fields, covered with plants bearing the berry, to re-plant them with these two species. The latter do not only come to earlier bearing, but the yield is far more heavy, and the bean is of superior flavour. As for Liberian coffee, of which so much has been written and spoken lately, "Eastward Ho" thinks that it has disappointed expectations in Ceylon, and whatever may be said of its success in the country where it is indigenous, it is safer not to counsel its cultivation beyond the limits of that country. On Cacao, the author reproduces Mr. Jardine's letter on the cultivation of the plant, which contains a mine of information on the subject, and anybody who wishes to try an experiment in its culture, cannot do better than follow explicitly the directions given therein. Cacao succeeds well in any warm locality exempt from high winds or hurricanes, at a comparative low elevation (say from 500 to 2,000 feet, according to latitude). The variety known as the "creole" is recognised the most favourably in the market, and the high rates now obtaining for "Ceylon" justifies the statement. In writing of the establishment of the cinchona industry, the author very truly observes, that it has proved a blessing to the world at large; besides, the profits derived by the manufacturer unfailingly, and in very many instances, too, to the grower;—exceptional cases have occurred in which the net returns realized per acre, have exceeded £1,000. He considers that the greatest service which *succirubra* has rendered in the past, is, "as a prolific begetter of a superior type of 'hybrids'—stronger in constitution, superior in growth, and, in several instances, richer than either parent, in the one alkaloid of high value, quinine." *Calisayas morada* and *verde* are also two valuable species, rich in alkaloids. A *morada* tree is mentioned as 150 feet high, and stout in proportion. The seed of their species is obtained from Bolivia, but there is a drawback in procuring it genuine; the jealous care of the Bolivians, as a body, in their desire to retain a monopoly of the best barks, having proved an almost insuperable barrier. "Cinchona seed," says the author, "should be thinly sown, in well drained beds made of a sandy vegetable mould, under chequered shade. Open and sloping waterproof thatch shades, the front supports, say, 5 feet high, answer admirably. The amount of direct sunlight can be very well regulated by a length of calico suspended in front. A certain degree of continuous moisture is of course essential, but frequent waterings should, as far as possible, be avoided, an occasional good soaking gently applied with a fine-rosed watering-can, probably answers best. It is useful, after having sown and given the seed a good preliminary watering, to sprinkle over it about $\frac{1}{4}$ th of an inch of powdered shagnum moss." There is a short chapter devoted to 'Cardamoms.' Its cultivation is altogether of a recent date, and, as an industry, must be credited to Ceylon. Here several kinds are indigenous, and the produce collected and sold by natives. The plant grows luxuriantly at moderate elevations, but it has been found to crop up well at an elevation of 4,500 feet. The returns of this industry are very encouraging indeed. One of the most unsanguine and cautious visiting agents in Ceylon, some time back, valued a clearing at £250 per acre. Mr. Middleton, of Coorg, who has carried on this cultivation for years past on scientific principles, has succeeded admirably, his returns being nearly a lakh of rupees a year. The next subject treated of is Rubber. Of all the kinds known to botanists, the species called *osera* is the most rapid in its growth, and shows a propensity of growing almost anywhere, provided the climate be equitably hot. The question being how best to collect the rubber at a profit, with the least injury to the trees? There are several methods practised, but the two best processes seems to be Wall's and Gilliot's, for which patents have been taken out. In connection with the nutmeg, "Eastward Ho," tells us that the tree does not bear until it is seven years old, and even then it takes seven more years to be in prime yielding condition. In Ceylon each tree gives an annual return of from 3lbs. to 5lbs.; a hundred trees should be

planted in a single acre of land; and he recommends that a few should be planted among tea bushes. Nutmeg trees are both male and female, and it is hard to tell the sex unless it is in flower; it is, however, usual to plant one male in a group of about fifty plants of the other sex. In the matter of pepper cultivation, there is an admirable contribution by Mr. Dobree, which almost exhausts the subject. Under the head of "fruits and fibres," mangosteen and pine-apple are prominently noticed. With regard to the former the author says, "it is true it takes many years to come into full bearing, but the fruits are so delicious and highly esteemed that they are always sure of commanding a ready and good sale; thanks to their tough outside shell they will keep sufficiently long to be placed in any local market, and as eventually the tree yields very heavy and regular crops, certain and large profits are to be anticipated from its cultivation;—if not in the present generation—the next." As for the pine-apple, it might be "tinned" for export, and the fibre which "is the most valuable of all fibres, rivals silk in quality, and . . . price for the raw article." The writer should not be surprised to hear, it had been valued at £80 a ton, or higher; and at only 5 cwt. per acre, this should pay. Areca Palm is the next in the order of notice, and we could not do better than reproduce what the author says about it:—

"To correctly realize the position of the 'nut' as a 'staple commodity,' it is sufficient to say that they are in daily use with, it is supposed, not less than 300,000,000 people. This will be better understood by making a mental calculation of the populations of India, China, Siam, Burmah, and the Straits Settlements, Ceylon, Java, and the numerous adjacent islands, the majority of whom, unless it be towards the north of India and China, are consumers. As to the number *per head*, on an average, disposed of *daily*, I can only say that I was pointed out the other day an old Sinhalese man who, so I was assured, considered 12 his just allowance (the poor fellow had not a tooth left, so could only manage the softer *green* nuts), and even quite small children get through two to three a day. But taken 6 per head as a fair basis of calculation, with the fact that it takes about 10,000 nuts to the cwt., though reducing the consuming public to 100,000,000, the result shown is, that the annual consumption amounts to 18,250,000 cwt.; an amount, large as it is, if the truth be known, should, I expect, be more than doubled for the one purpose only of chewing—rolled up in a betel leaf (the betel vine, by the way, is a species of pepper) with a little quick-lime paste, and, if possible, a tobacco leaf added; and of course there are other uses constituting it an article of commerce. An 'areca' tree takes from 5 to 6 years usually to come into bearing; after which it should average 300 nuts per annum, for 20 to 25 years. I have seen many trees with 1,000 and more nuts on at a time; but 300 may be taken as a safe and fair average. The number of trees to the acre should be from 1,200 to 2,000; and, I think, best planted in double-rowed belts, say 3 × 3 in the rows, and 15 feet between the belts; forming avenues over which the trees bend from each side, and in which other products such as cardamoms, ground-nuts, or possibly, even cacao or nutmegs, might be grown."

A little further on, he says:—"So positively little after-care seems a necessity, that it almost justifies it being said, that if a man planted up a 100 acres of suitable ground with 'Areca,' and went to sleep for six years, he would wake up to find himself in the receipt of a good income!" There are some valuable notes on the "Peruvian Cotton." The author is inclined to the opinion that the Yucas, a powerful nation that once inhabited portions of South America, and who were, not aborigines, but had probably migrated from Egypt, carried the cultivation of maize and cotton with them. Though they must have been placed under new conditions of climate and soil, yet after a long series of years they would alter from the original in *form* and *habit*—thus accounting for the maize being what it is; and Peruvian cotton, no longer an annually grown shrub, but a tree in proportions, and perennial." He is of opinion that over vast tracts of Northern Territory, the northern portions of Queensland, and Western Australia, the species will be found to thrive and yield to as great perfection as in the soil of the Peruvian deltas.

AGRICULTURAL EXHIBITION.

(FROM OUR OWN CORRESPONDENT.)

JULLUNDER, JANUARY 12.

THE station of Jullunder has been somewhat empty during the past month. One regiment has left, and its substitute has not yet come in. The 28th Native Infantry and the 88th, British, are both expected here, but they can scarcely arrive before the beginning of spring. They have not yet been relieved at their respective stations, Bareilly and Raulkhet. The Native Infantry will be the first to march in, some time towards the end of February. Meanwhile only one battery, the R-2 R. A., is here, and some of the officers went out shooting during the short Christmas leave. Moreover, the officials almost all availed themselves of the bright cold weather of December, and went out camping into the districts; thus it came to pass that the fine broad streets of Jullunder station and its well laid-out gardens became deserted. At lawn tennis some six or eight people assembled, and the bare untrodden courts looked desolate. In church a few heads and bonnets were visible on a vast area of brown benches; and feebly there rose the chant of the choir. During the last days of the month and the year the station suddenly began to fill up again. Officials returned from their tours of assessment and inspection, and officers from their shooting-trip. New-Year's day was ushered in by a midnight service, and a peal of bells from the Church tower. In the morning, between eight and nine, the battery paraded and the guns thundered their salute into the fresh cold air. At eleven a durbar was held in the Civil Lines, which lie close to the city, some three miles from the cantonments. The durbar-tent was pitched in the garden of the Town Hall. An address, excellent in style and in matter, and powerfully delivered, by Mr. Gordon Young, the Commissioner of the division, opened the ceremony. His speech was followed by a second address. A third address which a native official tried to deliver, and which threatened to be of great length, was fortunately suppressed in time. The durbar was well attended by Rajs and Sardars, the costumes worn on the occasion were rich and had a festive look about them. A few British officers had put in an appearance. In the evening at six, there was a display of fireworks in the gardens before dense crowds of natives and a gallery of Europeans.

But to pass on from fireworks to something more substantial: an Exhibition has been held here during the last fortnight, and this exhibition certainly deserves to be mentioned. For Jullunder is a large division, and the various articles which can be collected from its different districts will always make an interesting collection, and the managers did not confine themselves to the division. As you entered the verandah of the Town Hall, the first thing that struck your eye was a group of small figures, placed on a high pedestal. They represented a Punjabi peasant ploughing his field with a yoke of oxen, whilst close by, a few men are occupied, seated, or stooping, in the various attitudes of field-labourers. The life-like action of the obstreperous steers, the happy manner in which the gait of the zemindar and the fling of his arms are caught up, make this group a perfect work of art, and reflect credit on Mr. Kipling's school in Lahore, where it was modelled. I suppose this ploughman is a symbolical figure; for on a table close by are laid out various kinds of the fruits of the earth, species of wheat and seeds, rice and maize, gourd, sugar, cotton, opium, &c., and at the head of the table two gigantic pumpkins attest to the fertility of the Jullunder soil. Then come works of carpentering, most of which have been sent in from Kappurthala or Hoshiarpore. Little of the furniture exhibited presents a pure native style; it is either European, or shows a blending of European and Indian designs. Worth mentioning is an elaborate writing-desk containing a set of drawers craftily hidden, which are opened by the touch of a secret spring; and a lace-machine belonging to Mr. Akbar Ali, in Loodiana, which has already brought its owner a prize of Rs. 50, and which will yet bring him a patent. On a third table the earthen-ware are exhibited, jugs, pitchers, flower-pots, flower-stands, &c., things useful and useless, all made in Jullunder. The hardness of the earthen-ware, its glare and its colouring, render it superior to Peshawur pottery, and inferior only to that made in Mooltan. On a table close by, a few huge brazen hookah-holders attract our eye, a set of ornate candle-sticks, a number of padlocks from Hoshiarpore, big enough to be used for an Imperial treasury or jail; next we find laid out thick woollen carpets from Alawalpore, muslin, coarse but well-printed, from Phillour, pushminas, and most gaudy purdahs from Hoshiarpore. If the Hoshiarpore men use these purdahs to screen their wives from the world, they at least give them something very pretty as a partition. Some grey carpets from Mooltan show good workmanship, their designs are regular and in good taste. Loodiana carries off the palm in this competition of fineries, with a number of table-covers of black broad cloths of English make, the borders and corners of which are adorned with true Eastern arabesques wrought in gold, with silk puggies, grey, dark-blue, and lovely violet—with slippers, worked in imitation of the Cashmiri style, with some handsome fulkaris. It is now well-known that many of these Loodiana clothes are made with yarn brought out from England. Loodiana is almost rivalled by Umritsar. Mr. Daves Suloy Prub Dial sent in an assortment of shawls, slippers, ornamental shogras, etc. Another long table contains miscellaneous articles, amongst which our eye alights on ivory card cases exquisitely carved, on pencil-cases, steel with gold inlaid, on Kangra jewellery, Cashmiri imitation, &c. The Exhibition was crowded with natives from morning to evening. The Raja of Mandi who had come in on a visit, and his followers, helped to swell their numbers—needless to say, the European residents also appeared in *corpo*. The articles exhibited were all offered for sale, and the results ought to encourage the enterprising senders, for pretty well the whole collection of

things has been bought up. On New Year's day there was a cricket match between the station and the battery. At the first innings the station scored 115 against 75. But afterwards the fielding became slack, and the gunners, well in practice, walked away with the game. To-day the team of Native Christians play the Battery. Last year the Native Christians won, but I have not yet heard the result of to-day's match. Our military hunters, returning from their shooting-tours, do not give very bright accounts. No snipe, and but few ducks in the *jahils*.

Miscellaneous Items.

LORD RANDOLPH CHURCHILL has reconsidered the invitation of the Sylhet tea-planter, and now proposes visiting their district during the month of February.

COLONEL CADELL has succeeded in inducing some twenty Chinamen, belonging to Singapore and Penang, to go back with him to the Nicobars to start the formation of a Chinese settlement.

A CORRESPONDENT at the Shevaroyas, writing on the 12th instant, says:—"We are having some fine cold weather now, but we want a little rain to ripen the coffee, from the want of which the trees are not looking so bright as they should."

THE Secretary for Berar reports that the prospects of the *khari* crops are favorable, except in places where they have suffered from excessive rain. Cholera has appeared in the Akola and Balapore taluks. Cattle-disease prevails in the Basim district.

THERE is a very high mortality amongst cattle in Assam. Cattle-disease is responsible to a large extent, but it is also strongly suspected that many healthy animals are poisoned by *Chamars* for the sake of their skins, which find a ready market at Tezpor.

THE ceremony of turning the first sod of the Baroda water-works took place at Ajwa, thirteen miles from Baroda, with great *clat* on the 8th instant. In the evening his Highness gave a banquet to the European and Native guests, and there was a display of fireworks.

So late as Thursday last, great lumps of hail amalgam were still unmelted in a shady spot close to the office of a local paper at Lucknow. This fact is more conclusive than pages of descriptive writing, as to the severity of the previous Saturday morning's storm.

OWING to the threatened scarcity in the Bellary district, a sum of Rs. 10,000 has been placed at the disposal of the Collector for relief labor. The Forest Department have also received instructions to permit the cattle of the district to be driven into the forests on the Kurool hills for pasturage.

ON the representation of the Collectors of the Godavari District, that the sum of Rs. 752-8-0 had been subscribed, and Rs. 429 more had been promised, Government have sanctioned the grant of Rs. 500 in aid of the Agricultural Show at Rajamundry, and have asked for a report of the result of the exhibition.

ABOUT 300 emigrants will be despatched from Madras in the course of the next fortnight to the Mauritius. The ship *Raja of Oochin*, which returned to Madras a few days ago from the Mauritius, after landing the last batch of emigrants from Madras, will probably be chartered to convey the coolies now awaiting embarkation.

THE Australasian statistics for the year 1883 have just been published. The total population of the seven Australasian colonies is estimated at 3,012,451, distributed as follows:—Victoria, 917,310; New South Wales, 843,389; Queensland, 267,865; South Australia, 299,012; Western Australia, 31,233; Tasmania, 124,350; and New Zealand, 529,292.

A CONTEMPORARY visited the silos constructed by the Commissariat Department at Jellapahar, and was agreeably surprised to find both sheep and cattle eating the food with a fair amount of relish. This much has, he thinks, been fairly established that silos properly constructed of grass in good condition during the rains, will be found of value to all stock producers in the cold weather.

THE managers of the Batavia Zoological Gardens have applied to the Netherlands India Government for a grant of money, in aid of a scheme to rear carrier pigeons for use in war time. The commander of the forces, reporting favourably on the idea, has recommended a grant of one thousand guilders for the purpose, on condition of the authorities being kept fully informed of the progress made.

IN the past month the total quantity of tea shipped from Madras to Great Britain and Calcutta was 8,600 lbs., valued at Rs. 8,535. The coffee shipments were almost *nil*, the total quantity sent to Calcutta being only 24 cwt. Of suchon bark the shipments aggregated Rs. 44,775 for 319 cwt. In the month of November, 1,133 lbs. were shipped from Calcutta, and 13 cwt. from Beypore. The export trade in tobacco and cigars steadily on the increase, the shipments last month aggregating 3,068 lbs., valued at Rs. 2,187. Indian condiments are shipped to England in large parcels; last month, 112 cases were exported to Great Britain, France, Melbourne, New Zealand, &c., of the value of Rs. 3,273.

THE Darjeeling correspondent of a contemporary says that the tea season which has just come to a close has been far from successful. Of course, one of the chief causes of poverty of the results was the scarcity of rain. The suggestion, however, that this evil is being aggravated by the reckless manner in which forest and jungle have been cleared to make way for new gardens, is deserving of attention.

A REPORT by a Mr. Van Delden Laerne, on coffee-growing in Brazil, is expected to take up about 500 pages of print. To the report there will be appended two large maps of the coffee area in Brazil, namely, a geological one, prepared at Mr. Laerne's request by Professor Derby, a geologist at Rio, and a physical one shewing the coffee-growing districts and railway lines open for traffic therein, on the 1st January 1884.

A SERIES of tide-tables for the river Hooghly for the current year at Saugor Island, Diamond Harbour, and Kidderpore, have been published by the authority of the Secretary of State for India in Council and of the Port Commissioners in Calcutta. They have been prepared under the supervision of Major A. W. Baird, R. E., in charge of the Tidal and Levelling operations under the Survey of India, and checked by Mr. E. Roberts, of the Nautical Almanac Office in London.

A MOVEMENT has been set on foot in Tanjore to start an Industrial School, the result of the efforts made some months ago by some of the officials and well-to-do landholders of the district. Tanjore is famous for its colleges and its high and middle schools. From an educational point of view the district is, perhaps, the most advanced in the presidency. An Industrial School, which, we believe, has received the support of the Collector of the district, will, we trust, soon be an accomplished fact.

ON the 11th instant the Sutlej river rose, owing to the winter rains, three feet six inches. The flood swept away one of the small boat-bridges at Ferozepore, and breached the large bridge also. The rise and heavy flow continued for about twelve hours, when the river showed signs of abating. The new tramway embankment, under construction by the Sindh, Punjab, and Delhi Railway, was slightly damaged; but beyond this, no other harm was done. The waters have now subsided to their normal height.

THE net amount of customs duties collected in Bengal on all articles during the year 1883-84 was Rs. 2,04,87,365, showing a falling off, as compared with the previous year, of Rs. 1,63,282, or 7 per cent. The decline was chiefly due to a decrease of Rs. 1,40,473 in the export duty on rice, which is said to have been owing to a short crop. There was also a smaller decrease in the salt duty, and this also was attributed to the bad harvest throughout the province which had the effect of checking consumption.

ALTHOUGH the silk market in England, at present, is by no means in an encouraging condition, we see that an enterprising French gentleman at Mauritius is about to attempt the rearing of silk-worms in that island. The idea was first entertained by M. Descroizilles, senior, who planted a number of mulberry trees at Beau Bassin, where his sugar plantations are, and as these trees have now grown to a considerable size, the present proprietor is about to import eggs from Japan, and to commence the manufacture of silk.

A CORRESPONDENT calls our attention to the fact that Mr. Rustomjee Manackjee is not the only Parsee capitalist who is successfully turning his attention to agriculture. The wasteland in the Panch Mahals, to which we referred in our review of Mr. Dombhoy Framjee's "History of the Parsees," has been brought under cultivation, not by Mr. Manackjee, but by Mr. Ardeshar Dalal, of Broach, whose enterprise, as we recorded some months since, has been cordially recognised by Mr. Shepherd, the Commissioner of the Northern Division.

A PAPER was recently read before the Port Louis Society of Arts, describing the results of a first experiment in the manufacture of quinine, which had resulted in the production of 279 grains of quinine and 60 grains of cinchonidine from 2½ lbs. of bark, the variety of which was not stated. Having regard to the great prevalence of fever in Mauritius at certain seasons, and to the fact that a yearly sum of about Rs. 1,10,000 is expended in the purchase of home-made quinine, it is proposed to carry on the manufacture on a larger scale. It was stated that the Mauritius cinchona trees are subject to a disease caused by an insect, but unless they are very far gone, the diseased part may be removed and the insect taken out. The cavity is then covered with moss, and has to be kept damp for some days. The nature of the insect did not transpire.

THE amount of Indian tea exported from Calcutta in December was 7,157,796 lbs., as against 8,587,401 lbs. in December 1883, and 5,764,857 lbs. in 1882. The exports to Great Britain from 1st May to 31st December were 50,195,180 lbs., and in the corresponding periods for the two previous years they were 47,397,247 lbs. and 42,193,623 lbs. To Australia and New Zealand we exported 271,454 lbs. in December last, and 848,972 lbs. from 1st May to 31st December. For America in December the corresponding figures were 12,056 lbs. and 61,104 lbs. The total exports from 1st May to 31st December were 51,942,345 lbs., as against 47,056,206 lbs. in 1883, and 45,252,509 lbs. in 1882. In spite, therefore, of the fact that the half-yearly exports to the Australian Colonies were far short of the amount despatched in 1882 (2,251,062 lbs.), the trade as a whole shows a very considerable advance.

As a relief measure to sugar planters in Netherlands India, the Governor-General has passed an ordinance to be in force for one year, enabling them to hypothecate their growing crops. It is, however, generally held in Batavia that to save the planters from ruin, the native population dependent on the sugar estates from impoverishment, and the estates themselves, when sold off for debt, from passing into the hands of Chinese, this enactment should be followed by others securing sugar-growers exemption from taxation, and lowering railway freight rate.

THE yield of apples this year in the New England States is enormous, if not wholly unprecedented. The *Boston Commercial Bulletin* affirms that farmers hardly know what to do with the great crop at their disposal. England is the only market outside the States to which the immense supply can be sent, and hither will come all that can be profitably shipped. Many orchards are said to have yielded 500 barrels each, and one farmer has produced 700 barrels of 'Baldwins.' There are some counties in which the crop is quite small, and in others it is hardly worth gathering, but the cause of these exceptional instances of failure is not stated. So much of the supply of apples as cannot find a market in the natural state will be converted into cider and vinegar, of which the prices are expected to be very low. Good 'Baldwins' were being sold in Boston, at latest mail dates, at 6s. per barrel for export. Up to the 25th October this season the shipments of apples from Boston, New York, and Montreal had reached 152,640 barrels. Never before have the exports been so heavy at that date.

YEAR after year the State Fish Commissioners of Wisconsin and other States have freely stocked the waters of the lakes with young whitefish. Yet year by year the catch of whitefish diminishes until now the extermination of this valuable species of food is threatened. Where do the whitefish go to? The answer is not hard to find. Exhaustive experiments have been made and have proved that the artificial stocking of the lakes through the medium of State fish hatcheries is in itself successful. Healthy young fish by the millions—and more whitefish than fish of other varieties—have been deposited in Lake Michigan, and in spite of any adverse natural conditions, they have lived and thriven. But experiments have proved, too, that whitefish are exceptionally tender; and unlike many other and hardier varieties, they hug close to the shore, where the water is shallow and warm. These shallow reaches of the lake from Chicago to Buffalo are almost literally lined by trap nets, set by the dwellers along shore. In such nets, with fish of larger size, the partially grown whitefish are caught. When the nets are pulled up these latter are taken out and—not preserved for food, but—thrown back into the water dead, being too small for use. Thus thousands upon thousands are killed every year on almost every mile of shore line along the lakes. Here, then, is the reason why the food stock of delicate whitefish in the lakes is not increased, but rather steadily diminished year after year. There must be law, and the rigid enforcement of law, prohibiting the use of trap nets, or the free supply of the great lakes will be exterminated. The law to be effective must be a law of Congress also, for no State law and no combination of laws by different States adjacent to the lakes can meet the case.

Selections.

ON THE QUALITY OF CREOSOTE SUITABLE FOR PROTECTING HOP-POLES, WOOD FENCES, &c., AGAINST DECAY.

By DR. AUGUSTUS VOELCKER, F.R.S., CONSULTING CHEMIST TO THE SOCIETY.

COMMERCIAL creosote, a dark-brown thickish liquid, strongly smelling of carbolic acid, has been used for years past, as is well known, with much success, for protecting from decay hop-poles, stakes, and wooden railings, which, being made from young, and more or less immature or green wood, enter into decay, and become rotten and useless, after a few years, especially on naturally stiff and imperfectly drained land.

The creosoting process has been found so efficacious that it has almost completely superseded the older plans of impregnating wood with corrosive sublimate, as in Kyan's process, or with sulphate of copper, sulphate of iron, chloride of zinc, or other metallic salts.

Recently, however, several complaints have reached me respecting the quality of creosote with which my correspondents were being supplied. The creosoting liquid, it was alleged, when applied exactly in the same manner as in former years, entirely failed to protect hop-poles against decay; and Mr. F. de Lauue, to whom the merit is due of having used crude commercial creosote for preserving timber more than a dozen years ago with great success, and of having introduced this protecting liquid to the notice of farmers in his article in the journal of this Society, vol. xviii., part I., p. 259, goes so far as to say that, according to his recent experience, wood impregnated with

creosote supplied to him a year or two ago became rotten more rapidly than he believes it would have been had it not been subjected to the creosoting process.

Mr. de Laune's experience in past years, of having creosoted wood with entire success, compared with his recent failures, presents strong presumptive evidence of the quality of commercial creosote having become deteriorated of late years, in some cases to an extent such as to make it unsuitable for the preservation of hop-poles, wooden railings, &c.

Unfortunately, we possess no analytical data upon which a reliable opinion can be based respecting the quality of the creosoting liquid which ten or twelve years ago, and even earlier, had been used most satisfactorily. It is therefore impossible to make a comparison of the chemical composition of the creosote used in former years with great success, with that supplied in recent years, and alleged to be altogether inefficacious as a means of protecting timber against decay.

The liquid used for creosoting timber, known commercially as creosote, is a fluid possessing a highly complex and variable composition.

It is obtained from coal-tar, which, according to the kind of coal from which it is produced, yields the following products on distillation at a temperature rising to about 760° F.—

1. Pitch, remaining behind in the retort on distillation, and constituting the largest proportion of the products of distillation.

2. Naphtha, or benzol, the most volatile of the coal-tar constituents.

3. Ammoniacal liquor, which always mechanically adheres to, or is mixed with, the more specific tar-products of commercial coal-tar.

4. Light and heavy oils of tar.

The latter amount to from 20 to 30 per cent of the coal-tar, and constitute the creosoting liquor which is used for preserving timber.

Commercial creosote, in other words, is the portion of coal-tar which comes over on distillation between the temperature of about 350° F. and that of 760° F. It has a highly complex and variable composition.

Amongst its constituents may be mentioned: phenol, or carbolic acid; cresol, or cresylic acid, closely allied in character to phenol; naphthaline; light tar-oils, passing over on distillation at a temperature of about 600° F.; heavy tar-products which remain behind in the retort at that temperature, viz., pyrene, chrysene, leucoline, cryptidine, pyridine, acridine, and other organic bases which occur in minute quantities in commercial creosote.

The products of distillation of the liquid employed for creosoting wood are heavier than water, whilst the distillation products of animal and vegetable oils and fats, such as bone-oil, palm-oil, cotton-seed oil, resin-oil, and also whale-oil, have a lighter specific gravity than water.

Carbolic and cresylic acid, distinguished for their powerful antiseptic properties, were until recently regarded as the most valuable constituents of creosoting liquids, and are still held by some of the highest chemical authorities as the chief constituents upon which the efficacy of commercial creosote as a preserver of timber mainly depends.

This generally received opinion has been called in question by Mr. Boulton, of the firm of Burt, Boulton, and Hayward, the well known tar-distillers, who, in a paper read quite recently before the members of the Institution of Civil Engineers, on the strength of certain practical experiments, a long experience, and the testimony of several chemical experts, endeavoured to show that the efficacy of tar-acids, as antiseptics, has been over-rated at the expense of the more stable and enduring properties of the tar-oils. At the same time Mr. Boulton admits that the percentage of tar-acids in the creosote to be used remains a contested matter of opinion.

Notwithstanding all that has lately been said and written in favour of Mr. Boulton's view, it appears to me a hazardous proceeding to rely on the efficacy of a creosoting liquid which contains as little as 3, 4, or even 5 per cent of crude carbolic acid.

In preserving old, well-matured timber, such as is used for railways sleepers, and is less liable to perish than young immature wood used for railings, hop-poles, and light wooden structures, creosote, which is comparatively poor in crude carbolic and cresylic acid, but which is rich in heavy tar-oils, I can conceive may be quite efficacious in preserving such old timber; but when we have to deal with young immature wood, full of sap, I do not think a creosoting liquid, containing as little crude carbolic acid as I have found in creosote recently purchased, can be relied upon for its power of preventing the decay of hop-poles for a reasonable number of years.

Creosote, suitable for preserving hop-poles or wooden fences, in my judgment, should contain not less than 10 per cent of crude carbolic and cresylic acid; and if the percentage of these tar-acids rises above 10 per cent, the creosote will be all the better for the purpose of protecting the poles against decay.

In a sample of commercial creosote sent to me for analysis a short time ago, I found no less than 14.76 per cent of ammoniacal water.

This sample, on distillation up to 610° F., yielded only 39.08 per cent of products volatile at that temperature, including only 4½ per cent of crude carbolic acid. The ammoniacal liquor, amounting to 14½ per cent, is most objectionable; and 4½ per cent of crude tar-acids appears to me insufficient to neutralise the effect in the sap of young wood of those constituents which cause in wet ground its rapid decay if unprotected. There can be little or no doubt that a creosoting liquor of the character of this sample is altogether unsuitable for the purpose for which it was used.

Not quite so bad, but still anything but good creosoting were two other samples, recently purchased by hop-growers Kent. These samples contained respectively of—

	No. 1.	No. 2.
Distillate from boiling point to a temperature of 610° Fahr ...	39.08	61.75
Including—		
Crude Carbolic acid ...	3 per cent.	4 per cent.
Specific gravity of creosote at 60° Fahr...	1.102	1.103

I fear, under the name of creosote, tarry liquors are often sold to hop-growers which are not worth much, if anything, for protecting hop-poles against premature decay; and I would strongly urge upon farmers who are in the habit of creosoting wood, not to buy any creosote unless it is guaranteed of a well-defined quality.

The crown agents of the Colonies, the War Office, and probably other Government Offices, in entering into contracts for the supply of creosote, issue specifications to govern the quality of supplies of creosoting liquors. Tar distillers and dealers in creosoting liquors surely ought to know what they are selling, and farmers will do well to insist upon being supplied with creosoting liquor of a guaranteed quality. I would suggest the following specification, the adoption of which, I believe, would place dealings in creosoting liquors on a more satisfactory footing, and remedy the complaints which have lately been made respecting the bad qualities of creosote.

Specification to govern the quality of supplies of Creosoting Liquor.

1. The liquor must be free from the admixture of any oil or other substances not obtainable from the distillation of coal, at temperatures between about 350° F. and 760° F.

2. It must yield from 65–70 per cent of products when distilled from its boiling point to 610° F.

3. By repeated agitation with successive portions of a solution of caustic soda of spec. gravity 1.125 (25° Twaddell) the distillate must yield not less than 10 per cent of crude carbolic and cresylic acid (crude coal-tar acids).

4. The creosoting liquor shall contain not less than 20, nor more than 30, per cent of constituents that do not distil over at a temperature of 610° F.

5. It should become completely fluid when raised to a temperature of about 95° F., and remain so on cooling down to a temperature of 85° F.

6. The specific gravity of the liquor must not be less than 1.035, and not more than 1.065, water being 1.000, at a temperature of 60° F.

PRODUCTS OF CANADA AND THE NORTH-WEST.

AN exhibition of animal, vegetable, and mineral products of the North-Western Territory, particularly of the land lying directly to the west of Manitoba, is now open at 35, George-street, Edinburgh, under the auspices of the Canada and North-West Land Company. One of the features of the exhibition is a large distinctly-marked map, showing the enormous extent of the possessions and the localities from which many of the exhibits have been taken. The samples of cereals shown are obviously the produce of rich and fertile soil, and quite equal in appearance to that grown on the finest British fields. The wheat, which consists of white Russian and Scotch grain, is admirable in colour and solid in kernel. The latter, which is very extensively cultivated, is a favourite variety with Manitoban agriculturists, the land bearing as many as seven or eight successive crops without manure; while timothy grass, specimens of which are also shown, grown for a few years give the land sufficient rest to enable farmers to put it again under wheat. The samples of barley, oats, peas, and beans are also solid and bright in appearance, peas and beans being specially good. The land upon which these and wheats are grown is either clay or sandy loam, the richness of which is abundantly testified by the fine quality and weight of the grain. Another proof of the fertility of the soil is the enormous size of roots, such as mangels, turnips, carrots, potatoes, &c., it is capable of producing without the aid of manures or any artificial stimulants. The potatoes exhibited are very large in size, and apparently good in quality. An ordinary yield of potatoes in Manitoba is said to range from 250 to 300 bushels per acre. Turnips, mangel-wurzel, beet, squash, and similar vegetables attain large proportions, and the specimens exhibited are said to be of the average size. Of the grasses which cover the prairies and marshes, growing four to eight feet high, and most of which are relished by stock, there are numerous specimens; while the mineral products of the country, consisting of coal, gold bearing quartz, asbestos, and other valuable materials, are represented. Altogether the display, enhanced by a large variety of magnificent photographs of objects of interest to be seen from the Canadian Pacific Railway, which runs almost its entire length through the land of the company, is highly creditable, and, under the management of Mr. L. Bonny, agent, 668 Main-street, Winnipeg, is naturally attracting a good deal of attention.—*North British Agriculturist.*

FORECAST OF THE 1885 LINSEED CROP IN THE CENTRAL PROVINCES.

The following forecast of the outturn of the 1885 Linseed crop in the Central Provinces is just published by the Officiating Director of Agriculture:—The reports of six districts are still outstanding although due in my office by January 5th, but I think it better to make no further delay on their account, although they include the districts of Nagpur and Raipur which are perhaps the two most important linseed producers in the Provinces.

2. The district reports are on the whole very favourable. Linseed is sown three weeks earlier than wheat, and did not therefore suffer to the same extent as wheat from the early cessation of the monsoon rains. It is reported from two districts that there is a decrease in area, owing to the ground having become too hard for sowing, but this is a great deal more than counterbalanced by a general increase resulting from linseed having encroached on land ordinarily sown with wheat, and also from its having been sown on land which bore kharif crops during the preceding monsoon months, but which, owing to the excessive

rain, failed to give produce. There is also a steady annual increase in the area under linseed owing to the active demand for it. The export of linseed is, next to that of wheat, the most important feature in the export traffic of these Provinces, and cultivation is steadily responding to the demand of the Bombay market. The increase in linseed cultivation is especially marked in districts such as Nagpur, in which much of the soil is not of sufficient depth for the produce of wheat, and where the growth of linseed is increasing at the expense of the cotton and the millet crops. It does not seem extravagant to assume an increase of at least 10 per cent in the linseed area of the current year.

3. The prospects of the standing crop are also satisfactory. Rain was much wanted for it a month ago, and in some places the plants were beginning to wither. But rain has now very generally fallen and the crop has immensely benefited. A little harm has resulted in the Raipur district from the ten days of cloudy weather at the end of December, which have been prejudicial to the proper fertilization of the flowers, but after making allowance for this, a full crop may be expected in Raipur as well as in Bilaspur; and the reports from other districts show that prospects are very nearly, if not quite, up to the average throughout the Provinces.

DISTRICT.	Percentage by which the area under linseed exceeds (+) or falls short of (—) that of previous year.	EXPLANATION OF DIFFERENCE IN AREA.	Estimated out-turn in annas per rupee taking 12 annas to represent an average out-turn.	REASONS FOR ESTIMATE.
Saugor ...	—12	Excessive rain prevented preparation of land during monsoon.	10	Had not rain recently fallen, the prospects would not have been nearly so favourable.
Damoh ...	+25	Linseed has been largely sown in place of wheat, since the land could not be sufficiently well ploughed for wheat, owing to the heavy monsoon rain.	10	The recent rain has in places been insufficient.
Jubbulpur	No return received.
Mandla ...	+31	Area has been increased, consequent on increase in demand for linseed.	12	Crop appears very healthy. A little more rain would do good.
Seoni ...	+2	10	Growth has been checked by lack of moisture at germination time, owing to early cessation of monsoon rains.
Narsinghpur... ..	—15	The monsoon rains ceased early, and the ground hardened before the whole area could be sown.	12	The crop is promising well, but the total outturn will be diminished by the decrease in area.
Hoshangabad ...	+9	The area shows a considerable increase in two tahsils, owing to the increase in the demand for linseed.	9	The late rain has been very beneficial.
Nimar ...	+50	Land on which the autumn crops were ruined by heavy rain, has been re-ploughed and sown with linseed.	11	The December rain has proved generally very beneficial.
Betul ...	+6	Linseed has encroached upon wheat, owing to the peculiarities of the last monsoon season.	10	Before the late rains the crop had begun to wither.
Chhindwara ...	+4	Linseed has been sown on land on which cotton had been sown in the preceding monsoon. It has also encroached on wheat.	10	The late rain has been very seasonable.
Wardha	No return received.
Nagpur	No return received.
Chanda	8	Lack of rain has injured the crop.
Bhandara	No return received.
Balaghat ...	—3	Owing to the early cessation of the monsoon rains some land could not be sown.	11	Cloudy weather is injuring the flowers.
Raipur	No return received.
Bilaspur ...	+10	Area increasing in consequence of increase in demand.	16	The crop is in excellent condition, and unless damage is done by frost or insects, the outturn will be above average.
Sambalpur	No return received.

THE INCUBATION STAGE AND SPREAD OF GLANDERS.

WILL you oblige me with some information on glanders, as I have been unfortunate enough to have four horses shot with that disease in six weeks? I wish particularly to know how long the disease may remain in the system without showing itself, whether it occurs spontaneously, and whether in the early stages there is any curative treatment?—ESSEX.—[Glanders, like rabies and some other animal poisons, has an irregular and somewhat protracted period of incubation. When glanderous matter is introduced directly into the horse's body by inoculation, its effects are produced usually within seven days, and are of a pronounced and violent type. When the ass is subjected to such inoculation, the glanders symptoms follow still more rapidly, and with greater acuteness. It is obviously difficult in many cases to determine the exact date at which sound horses have contracted the foul disorder from affected subjects worked, stabled, fed, or watered with them. Cases are recorded where the preliminary shivering, elevated temperature, and disturbed temperature, characteristic of acute attacks, have been observed within ten days after the animal, previously in sound health, had been in contact with a glandered or faroed subject. More frequently, however, the incubation stage extends to three or four weeks, and in some instances to double that period. The incubation stage in this, as in other disorders, is doubtless also modified by the amount and virulence of the contagion, and by the state of the

animal receiving it. There is much difference in the power which different horses exhibit of resisting the glanderous poison. Some with impunity live for years in foul stables amidst chronic cases of farcy, which is merely glanders affecting the external glands and vessels, and even with glandered subjects condemned from the next standing. Foul air, bad food, hard work, reducing diseases such as diabetes and influenza, and other depressing causes, are great predisponents of glanders; but it is doubtful whether any such insanitary conditions actually produce glanders, or, in other words, whether it ever occurs spontaneously. The consensus alike of scientific and practical observation point to glanders, as well as its milder external form of farcy, being determined only by the specific virus. This will appear more obvious, when it is considered how widely distributed the germs of the disorder still are, in spite of the Contagious Diseases (Animals) Act of 1878, and the increasing precautions certainly taken by horse-owners to isolate suspicious cases. In most towns, amongst the hardest worked and worst housed horses, there still continue cases of chronic farcy, which, although sometimes curable, produce acute glanders, not only by inoculation, but by disseminating from their discharges particulate germs, which may develop acute glanders. In considerable studs of hard-worked animals there are, moreover, not unfrequently, suspicious subjects with intermittent or chronic nasal discharge, and which, although quite free of the ulcerated nasal membrane, are really glandered, and prove disseminators of the disease. Still another unsuspected source of the virus are horses with glanderous tubercles in the air passages, producing chronic cough, and perhaps some thriffliness

INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA :—SATURDAY, JANUARY 31, 1885.

[No. 5.]

Crop and Weather Report.

[FOR THE WEEK ENDING THE 21ST JANUARY, 1885.]

General Remarks.—Rain has fallen in Sind and in some districts in the North-Western Provinces and Oudh, Punjab, and in the Central Provinces. There has been slight rain also in the Central India and Rajpootana States. Rain fell in some districts in Bengal.

Agricultural prospects continue improved since last week. In Madras general prospects are good in Bellary and Anantapore, where the standing crops are in good condition. In Mysore, except in the Tumkur district, standing crops are in good condition. In Coorg, the paddy crop has been a good one, and is approaching completion; the out-turn is good, and the estimate is high.

In Bombay the prospects are good in one or two places. Drinking-water and are scarce in some places.

In the Berars, Hyderabad, the Central India, and Rajpootana States, agricultural prospects are favourable.

In the North-Western Provinces, Oudh and Punjab, the standing crops are in good condition and prospects are generally good.

Seasonable weather prevails in the Central Provinces and prospects continue favourable.

In Belgaum the rain of the past week has been beneficial to the crops which are generally doing well. Harvesting of *aman* paddy and cutting of sugarcane continue, and mustard and *kulai* are being gathered in some places. In Assam crop prospects are good, and in British Burmah fair.

Cholera is abating in Coimbatore, but in Tanjore, Madura, and Malabar the mortality is still high. Elsewhere in the country the public health is generally fair or good.

Prices are falling in the North-Western Provinces and Oudh and in the Punjab.

Madras.—General prospects fair, except in parts of Bellary and Anantapore.

Bombay.—Rain in parts of Sindh; cotton in parts of Hyderabad and other crops in parts of Shikarpore injured by rain and frost; *rabi* prospects good except in parts of Kaladgi and Belgaum; cotton suffering from blight in parts of Dharwar; scarcity of fodder in four talukas of Dharwar and two of Kaladgi, and of drinking water in two talukas of Dharwar; cholera in parts of six districts; fever, small-pox, and cattle-disease continue in parts of several districts.

Bengal.—Some rain fell, benefiting the *rabi* crops which are generally doing well; mustard and *kulai* are being gathered in some places; harvesting of *aman* paddy on low lands is still going on in many districts; cutting of sugarcane continues; prices of food-grains are almost stationary; cases of cholera are still reported from many districts and small-pox from several, otherwise public health good.

N.-W. P. and Oudh.—There was slight rain but beneficial during the week; hail in some places with inconsiderable damage; crops are flourishing, and prospects excellent; the paddy crop promises well; markets are well supplied and prices tend to fall.

Punjab.—Fever nearly disappeared in the Umballa district; health and crop prospects of the rest of the province good.

Central Provinces.—Weather seasonable; rain reported from northern districts; prospects continue favourable; health generally good; but cattle-disease again reported from Raipore; prices steady.

British Burmah.—Cholera severe in Akyab and Prome, slight in Bassein, Tavoy, Hensada, Kyaukphyu, Sandoway, and Thongwa; elsewhere public health, and health of cattle good; crop prospects fair.

Assam.—Weather wet; prospects of sugarcane and mustard good; *sali dhan* nearly harvested; district healthy.

Mysore and Coorg.—Paddy crop nearly harvested; a little coffee remains to be picked, out-turn short and in most cases below estimate; food grains show a tendency to rise, the market being affected by that of Mysore.

Berars and Hyderabad.—Weather clear and cool; cotton-picking continues; *khari* being rapid; *rabi* crops progressing favourably; wheat 22, and *javari* 26 seers per rupee.

Central India States.—Weather clear and cooler; slight rain during the week; health good; prospects of *rabi* crops and opium favourable.

Rajpootana.—Weather seasonable; prospects favourable; prices steady; health good.

Letters to the Editor.

PLANTAIN FIBRE.

TO THE EDITOR.

SIR,—I have read with great interest the Government report sent the late competitive examination of the fibre-extracting machinery in the columns of the *Indian Agriculturist*. However, I am a little disappointed at the result so far, as nothing satisfactory appears to have come out of it, regarding the extraction of fibre from the plantain stems.

On this side of the country, we scarcely come across that moist and humid climate that so well agrees with the fibrous plants, and hence it is that its cultivation is very much restricted here. However, where there is a good market, we find the plantain numbering as one of the local garden crops. This is the case throughout the whole country, being cultivated in some places to such an enormous extent, that it is worth while to devote some attention to manufacture of fibre from its stems.

Hoping to be further enlightened in this direction through the columns of your valuable journal,

AN INQUIRER.

Bombay, January 26, 1885.

Editorial Notes.

It will surprise a great many of our readers to learn that what is popularly known as lead pencil, is no lead pencil after all, and there has been none for the past fifty years. There was a time when the industry was yet in its infancy, and a spiracle of lead, cut out of a bar or sheet, sufficed to make some sort of marks on white paper or some rougher material. The name of lead-pencil was derived from the old notion that the products of the Cumberland mines, were lead, instead of what it was, *viz.*, plumbago, or graphite, a carbonate of iron, capable of leaving a lead-coloured mark. With the original "lead" pencil made direct from the mines of Cumberland, it was necessary to wet the point, or it would not impart a black colour to the material on which it was used. But since it has become a manufacture the lead pencil is adapted, by various marks, to each particular design. There are different grades of hardness from the three H's, that may be sharpened to a needle point, to the three B's that are almost as soft as wax and make a broad mark. Between these two extremes there are a number of gradations that serve all conveniences and all purposes for which a lead pencil is used. These different hardness are regulated by taking the original carbonate and grinding it, and mixing it with a fine quality of clay in varying proportions, regard being had to the purpose to which the pencil is to be applied. The compounds are thoroughly mixed; the mass is squeezed through dies to form and size it, is dried, and encased in its wood envelope.

.

It is an admitted fact that the greatest discoveries of modern times have been made by men who have not only had the patience to carry on experiments, but also the leisure to prosecute their investigations, and above all, personal liberty, which is in fact the *sine qua non* of great achievements. But there have appeared, from time to time in the world's history, men who have been able, in spite of almost insurmountable difficulties, to make discoveries that may be said to have conferred

a lasting benefit on mankind. Even the isolation of a prison cell fail to damp the energy of men who are bent on carrying out their purpose. Of such a stamp was the political prisoner Kammerer, the inventor of lucifer matches, who perfected the idea in 1833, within the walls of a state prison. He was a native of Ludwigsburg, and when sentenced to six months' imprisonment at Hohenasperg, he was fortunate enough to attract the notice and to gain the favour of an old officer in charge of the prison, who, finding he was studying chemistry, permitted him to set up a small laboratory in his cell. In those days the steeping system was in use, which consisted in dipping splinters of wood, with sulphur at the ends, into a chemical fluid in order to produce a flame. If the fluid was fresh, the result was satisfactory, but as it lost its efficacy after a time, there was no general disposition to adopt it in preference to the old-fashioned system of using flint and steel, and it was with a view to remedying this obvious defect, and improving on it that Kammerer undertook his researches. Of course, in the beginning, failures were inseparable, but Kammerer was not a man to be daunted by temporary checks or disappointments. He devoted his heart and soul to the work before him. He commenced experimenting with phosphorus, and just before completing his term of imprisonment, he discovered the right mixture, and kindled the first match by rubbing it against the wall of his cell. On being released he commenced manufacturing matches. But, unfortunately, there was no patent law in those days, by which his rights could be secured, and before long he had the mortification to find a well-deserved fortune slipping out of his hands; for Austrian and other chemists analyzed the composition, and imitations began making their appearance. Two years later, that is, in 1835, the German States prohibited the use of these matches, as they were considered dangerous. They were then made in England, and exported to the continent when these regulations were withdrawn, but too late to be of any benefit to the inventor, who became a lunatic, and died in the mad-house of his native town in 1857.

.

An article in a Burmah paper on the probable failure of the rice crop in that province, has given rise to some discussion on the danger to be apprehended by the productive power of the land. Various suggestions have been made to the local Agricultural Department on the subject. Some are for introducing the cultivation of jute, others of wheat, sugarcane, &c., &c. A correspondent, however, is of opinion that no product promises so much as silk, and it is surprising no one has devoted his attention to it. "The country," he says, "abounds in it—wild and cultivated; its quality is second to none in the universe and its cultivation is easy," and that as the trade of the province is expanding, and that the expansion is based on sound principles, he sees no reason why the cultivation of silk should not be persevered in. He shows by statistics that the imports of the article by sea and land, for the three official years ending 1879-80, were by sea in 1878-9, 9 lakhs, in 1879, 11·6 lakhs, and in 1880, 13·6 lakhs; by land they were '4, '3, and '33 lakhs in three years. It appears that silk is not exported by sea, but by land the exports for the same period were 8·4, 10·9 and 9·7; calculating the consumption within the province itself 1·04, 1·07 and 4·20 lakhs respectively in each year, the figures give some idea of the needs of British Burmah in raw silk. The annual average during that period is two lakhs, but "two lakhs," says the writer, "is only a part of the capacity of the country for the consumption of raw silk." A large quantity is manufactured locally. In the towns and villages of Prome, Tharrawaddy, Bassein, Thyetmyo, Shoaigyeen, and Toungoo there are 3,000 breeders who raise worms. There are said to be 900 dealers in silk in fibre, and about 2,000 persons are engaged in converting the fibre, locally manufactured and imported, into cloth. The same authority gives the following figures of the imports and exports by sea and land of silk manufactured during the period above referred to:—

	1878.	1879.	1880.
<i>Imports.</i>			
Sea	... 89·2	50·4	40·
Land	... 10·7	16·6	11·
Total	... 80·	67·0	51·

	1878.	1879.	1880.
<i>Exports.</i>			
Sea	... 05	04	02
Land	... 17·3	17·8	23·1
Total	... 17·35	17·84	23·12

Now deducting the latter figures from the former, the balance left is what may be termed home consumption of the silk manufacture: for 1878, it is 32 lakhs; for 1879, 50·6 lakhs, and for 1880, 27·8 lakhs. But in the raw silk the annual average of the home consumption as shewn above is two lakhs, and the conclusion the correspondent, Mr. Manuel, arrives at is, "that the total annual average value of silk, raw and manufactured, consumed in this province during the years from 1878 to 1880 amounts to the sum of nearly 40 lakhs of rupees." It appears that he had suggested the idea to some people in Bombay, and supplied them with these figures, for he says that some of the mills there have sent manufactured articles to Burmah, "displacing, to the extent of the shipments, that which used to be obtained from the United Kingdom." His opinion, and he is thoroughly competent to speak on the subject, is that there is not a province in all India that consumes so much silk as Burmah.

.

THE average area under wheat in India in ordinary years, according to a recent estimate, is about 26,000,000 acres, and the average gross production is nearly 7,000,000 tons. Of this area 18,000,000 acres, or 9/13ths, lie in the four British Provinces of the Punjab, the North-Western Provinces and Oudh, the Central Provinces, and Bombay. During the last year a system of monthly forecasts of the condition and prospects of the wheat crop was tentatively started in these four Provinces, and reports for the months of November and December have now been received. In the Punjab the sowings are above the average, and prospects are considered excellent. The area under crop is estimated at 7½ million acres, the average area being 6½ millions. In the North-Western Provinces and Oudh, the November forecast was exceptionally favourable. An area of 5½ million acres had been sown against an average of 5 million acres, the seed had germinated well owing to the late October rains, and a bumper crop was predicted. The December forecast, however, is less favourable, as owing to the entire absence of winter rains the young crop has somewhat suffered. "If moderate rain falls in January," the report states "the crop will still be above the average." Rain has fallen in the Province within the last few days, so that the present prospects of the crop are somewhat better than appears from the December report. In the Central Provinces, owing to the early cessation of the monsoon rains, a smaller area than usual has been sown with wheat. The average area of recent rains has been nearly 4,000,000 acres. This year the decrease ranges in the several districts from 5 to 10 per cent. Present prospects are all that could be desired, as owing to recent rain the crop is in an excellent condition. "Were it not for the contraction in area," the report states, "the gross outturn would be above the average."

.

THE Bombay report for December has not yet been received, but the November report stated that, "generally speaking, the area and condition of the wheat crop are satisfactory in the Gujerat districts, though the crop area and condition in the Deccan and Carnatic districts are unsatisfactory from want of rain." From other sources of information, it is believed that this is still a substantially correct description of the present year's wheat crop in Bombay. The average area under wheat in the Presidency has been estimated at about 1 3/5 million acres. A special report has also been received from the Berars, which estimates the present year's crop at 845,000 acres, or 5 per cent above the average, and states that the crop is in good condition. The general conclusion from the above is that in respect of over eighteen million acres, or nine-thirteenthths of the gross wheat area of India (including Native States), the condition and prospects of the wheat crop are on the whole up to the average, and that a bumper crop may be expected in the most important province of all, the Punjab. Information from Rajpootana and the Central India States, which have conjointly an average area under wheat of about

five million acres, lead to the conclusion that there also the wheat crop, in area and condition, is quite up to the average.

Ever since the outbreak of cholera in the East and in Egypt, great alarm has been felt in America over the importation of rags from infected districts. This led the Seymour Paper Company to cast about for means of disinfecting them before shipping them to the United States. In December 1883, Mr. C. E. O'Hara, the President, having learnt that boiling water would kill the disease germs in the rags, visited Boston, New Haven, and New York, and enlisted the co-operation of the health officers there. After experiments had been successfully tried, the experts unanimously pronounced their opinion that boiling rags for four hours would disinfect them of any impurities that may be secreted in them. Armed with these credentials the company went to work in right earnest. They got their machinery together in an incredibly short space of time, and forwarded them to Alexandria in February 1884. The machinery consists simply of three large wooden tubs, eleven feet in both diameter and depth, holding each ten tons of rags, and one engine of forty horse-power, and the necessary apparatus for drying by hot-air. No sooner the Egyptians heard of the arrival of the machinery than they commenced bringing in large quantities of rags from the villages surrounding Alexandria, at the rate of from 5 to 15 tons per day, and seventy Arabs were employed in the "spoonah"—Egyptian term for rag-house—dusting them. After the rags been cleared of superficial dust, they were thrown into the wooden tubs and covered with water. Steam from the generating boiler under 60 pounds pressure was then conveyed through a large pipe passing through the bottom of the vats to within a foot of the top, and surmounted by a dome-shaped roof. The apparatus is known by the name of "vomiter," and the steam bursts through at intervals, throwing the hot water in the pipe against the roof which scatters it over the rags. By this process the rags are in boiling water within fifteen minutes, and four hours after are taken out and thrown into the drying machines. The change that comes over the rags, after they have been submitted to this operation, can be seen at once; they are not so dingy or dusty as those that were brought some weeks previously without being disinfected. The supervisor who remained for upwards of eight weeks, in charge of the machinery at Alexandria, says that during the entire period work was carried on, there were 70 Arabs employed in handling the rags as they came in from the cholera districts, and he did not know of a single case of absence from duty on account of sickness. He accounts for it on the supposition that previous to the rags being conveyed to Alexandria they must have been lying on the ground under a burning sun, which so heated it as to destroy the disease germs. Encouraged by the results, additional machinery have been sent out; the total cost of the latter, including transportation, &c., is estimated at 20,000 dols., and the cost of disinfecting the rags, is a trifle less than a quarter of a cent per pound.

The last number of the *Journal of the Society of Arts* publishes, under the title of the "Forests of Russia," a summary of a report drawn up by Mr. Herbert, Secretary of the Embassy at St. Petersburg, on Russian Forests. Of course, it is a matter of extreme difficulty to hazard speculation as to even an approximate idea of the area covered by forests in the Russian Empire, covering as it does, portions of three-quarters of the inhabited globe. But so far as European Russia and Poland are concerned, it has been estimated by competent authorities to contain 354,572,000 acres. The last returns, however, show that this is an under-estimate and for the 871,576,914 acres in European Russia, exclusive of Poland or Finland, about 367,400,000 acres or 42 per cent is represented as being covered with trees and shrubs, but of this only about 80 per cent, or 292,920,000 acres are capable of bearing forest trees; so that not 42 per cent, but nearly 33 per cent, of the total area of the country may be reckoned as forest land. It is very unevenly distributed over the whole country; some governments have forests to the extent of 50 per cent of their total area, and others not more than 3 per cent; out of the 49 governments into which Russia

is divided, in four of them three-fifths of the whole forest land is concentrated, which leaves but two-fifths to the other forty-five governments. The following statistics furnished by the *Journal of the Society of Arts*, will be found very interesting:—Dividing the Empire into seven zones, it would be found that the northern and eastern governments have 54 per cent of their area forest; those governments adjacent to the Volga, 23 per cent; the governments in the centre of the Empire, 15 per cent; the Baltic provinces, 16·8 per cent; the North-Western Provinces, 23 per cent; the Ukraine, 14 per cent; and the Steppe governments, 1·3 per cent. Of the total area under forests, viz., 183,700,000 desiatines,* 122,944,000 belong to the Crown, but of this 99,000,000 desiatines can be taken as productive forest land. In Poland, 787,514 desiatines belong to the Crown. Up to the 1st January, 1882, 10,872,000 desiatines of the Crown forests, or only 8 per cent, were under properly regulated forest control. In the North and North-Eastern Provinces the Crown possesses 79 per cent of the forests; in the Volga, 33 per cent; in the Baltic provinces, 27 per cent; in the North-West and Ukraine, 22 per cent; and in the Steppe country, 15 per cent. According to the population, Russia has 2 desiatines of forest per head of population; Austria, 0·47; Germany, 0·33; and France, 0·2. Owing to the climatic conditions of the Empire, a great variety of trees thrive in the forests of Russia. If a line be drawn from Orenburg towards the west, through the governments of Samara, Penza, and Tamboff, as far as Iula, then to Charkoff, Kieff to Volhynia, it may roughly be said that south of this line deciduous trees will be found to predominate, and coniferous trees to the north of it. The *Pinus sylvestris* is the predominating forest tree, as far as 67° north latitude. It is to be found over two-thirds of the extent of Russia in Europe, predominating in the north, and found in the south only in isolated cases. It is found, however, as far as 70° north latitude, and towards the east as far as the Petchora, 66½° north latitude. The southern boundary where this species is found is at 41½°, but passing over the Steppes it is found again in the Caucasus, at from 41½° to 43° north latitude.

Abies excelsa takes the second place, and in Finland is found as far north as 68½°, and extends to the south as far as the north boundary of the black-earth country; in the east the variety *Abies obovata* predominates. The larch (*Larix Europaea*) is only found in Poland. The Siberian larch is found throughout the governments of Olonetz, Nijni-Novgorod, and the Ural as far as the River Sakmara (51½° north latitude), and yields excellent wood for ship-building. The cedar reaches in the north-east to 64½°, and in the northern part of Orenburg to 51° north latitude, and in the governments of Perm and Volgoda are large forests of this tree whose cones are exported very largely. Of the deciduous trees the following are found:—The birch and its varieties; the oak, which is not found further north than St. Petersburg and South Finland; the aspen, which, like the birch, flourishes almost throughout the country; the lime tree, which is chiefly to be found in the governments of Volgoda, Perm, Kostroma, Kazan, and Simbirsk, and is employed in the best manufactories, and in the making of matting which is largely exported; the red beech, which grows largely in Volhynia, Podolia, Bessarabia, and in the Crimea, and flourishes at heights varying from 1,500 to 4,000 feet above the level of the sea; the white beech, which is chiefly found in the south-west of the Empire, and also in the Caucasus and the Crimea, and in the neighbourhood of Kieff and Poltava it constitutes whole forests; the elm, ash, maple tree, alder, and willow are also found in the different varieties throughout the Empire, as also the wild apple, pear, and plum tree. In the northern provinces the cutting down of trees and sawing them into planks forms a very large and exceptionally profitable trade, and a very large population is employed in floating timber or barges laden with firewood down the rivers to the ports of export or places unable to supply themselves with wood. Thus Kostroma, Yaroslavl, Nijni-Novgorod, Kazan, and Viatska supply building timber for the Volga and its lower tributaries, down even as far as the Steppes of the Don. The principal use that the logs floated down the rivers as rafts or

* NOTE.—A desiatine is equivalent to a trifle more than two acres.

sawn into planks are put to in Russia, is that of house-building, for which purpose it is reckoned that 30,000,000 cubic feet are annually used. According to Professor Stieda, out of 1,820,000 inhabited houses in the central agricultural districts, that is, in the governments of Riazan, Tula, Kaluga, Orel, Kurah, Voronezh, Tamboff, and Penza, only 74,000 are built with stone and mortar, and in the manufacturing districts, in the governments of Moscow, Tver, Yaroslav, Kostroma, Nijni-Novgorod, and Vladimir, out of 1,400,000 inhabited houses, only 6,800 are built of stone. The amount of wood delivered from the forests of the Crown amounted in 1880 to 727,000,000 cubic feet, and the income accruing to the Crown from these forests for the same period exceed 13,600,000 roubles, or £2,100,000. Although the income from the forests has increased considerably, about 50 per cent of the gross income is required to cover the expenses of administration, &c.

.

THE following is a summary of Messrs. William James and Henry Thompson's Fortnightly Circular, ending 1st January:—The Tea market has been practically closed during the past fortnight, the public sales having been suspended, and only a limited business transacted privately. To-day the auctions were resumed, 4,322 packages being catalogued, of which 3,788 packages were sold "without reserve." The biddings were brisk at slightly firmer quotations for low priced Pekoes and Pekoe Souchongs, but Common Broken and Fannings were a little cheaper than in December. There was no fine Tea in the sale. The deliveries of Indian Ceylon during December were 5,415,000 lbs. as compared with 4,805,000 lbs. in 1883; the heavy imports have brought up stock to 27,076,000 as compared with 24,116,000 in 1883. The shipments from China at date of latest advices were seven million pounds less than last season. The visible supply of Indian Tea, including stocks and shipments afloat, is 31,000,000 lbs. as compared with 30,500,000 lbs. last year at the same time.

.

THE Lahore paper says:—If the Agricultural Departments, now scattered broadcast over the land, fulfil no other object, they at least deserve the credit of giving a quietus to the many new fads in food-staples, as well as agricultural implements, that enthusiasts wish to be tried experimentally for the good of the Indian ryot. We have seen the *Reana luxurians* condemned, as unfitted for the modest capabilities of this much instructed being; and another illusion is disposed of, in the wise decision of the Punjab Commissioner of Agriculture not to continue experiments in the cultivation of the Japan pea or *Soya Hispida*. This pulse, which was destined by its admirers to be one of the regenerating influences in Indian agriculture, has, like its many predecessors, turned out an almost absolute failure. Where sown, it has either failed to germinate, or where it has germinated, it has failed to come to maturity; or if it has come to maturity, it has given such a miserable outturn, that its cultivation would be a dead loss to the cultivator, who can make more out of his ordinary pulses (*mól*, for instance, or *phaseolus aconiti folius*) than out of the much vaunted Japan pea, of which the Honorary Secretary of the Lahore Gardens says:—"The soy bean is of no particular value as a pulse, and would never have been heard of, except for the fact that, soaked in water, it ferments and produces a brown liquid, the soy of commerce. There is no hope, that if even if the plant grew here, soy could be made, and if it were, the result would be of no advantage to any one whatsoever."

.

In a country like India, where the climatic influences at work render it imperative to keep rust off machinery and implements, it is important to keep in mind the following receipt. The *St. Louis Age of Steel* advises the use of 1oz. of camphor, dissolving it in 1lb. of melted butter; take off the scum and mix in as much fine black lead as will give it an iron colour, clean the machinery, and smear it with this mixture. After twenty-four hours, rub clean with soft linen cloth. It will keep clean for months under ordinary circumstances.

THE *Paper World* says that a short while ago it has been discovered that an excellent filler and substitute for wood pulp can be made from a pulpy fibrous material, found only in St. Lawrence county, N.Y., and is only known there in a circuit of about one mile. Messrs. Bayand and Stevens, of New York, are manufacturing it into qualities suitable for all grades of paper, and placing it upon the market under the name of Aabestine pulp; most of the larger paper mills are using it extensively, and the demand is growing so fast that the output has had to be materially increased in order to keep pace with the demand.

.

Most of our readers are aware that once upon a time a large trade was carried on between the Southern hemisphere and Europe, in the manure known as guano. It was popularly believed to be the excrement deposited by sea birds that visited the islands in the Pacific Ocean. That theory is exploded, and it is now proved that, instead of being produced by birds it is in fact of marine origin, being thrown up by the ocean, though it is likely that birds might have slightly augmented the original stock. The trade in the article, however, has declined considerably. The prevailing belief is that the quality has deteriorated, and its use is not attended with the beneficial results as formerly. According to the *Indian Gardener*, it is more than likely that the quality has remained as it was, but that the land is sick of the one thing used, as it will get tired of bearing one continual crop. Our contemporary advises change in manure as in any other treatment of the land such as ashes, bone-dust, lime, or other stimulants should be tried in turn.

.

SOME idea of the colossal character of irrigation works in Bengal may be gathered from the fact that the total capital outlay amounts to Rs. 6,37,00,000. This enormous sum has been expended to a large extent upon productive works, the remaining heads of expenditure being—Famine relief protective works, Rs. 30,00,000; Imperial ordinary works, Rs. 8,26,524; and Provincial works, Rs. 79,04,134. The receipts of the canals classed as productive works, in 1883-84, amounted to upwards of eleven lakhs of rupees, but this sum is considerably less than the receipts for the past two years. The balance of water rates outstanding on the 1st of April was Rs. 6,20,287 as against Rs. 5,75,788 in the previous year. The working expenses came to over ten lakhs, so that the net revenue realised was Rs. 1,00,447 against Rs. 1,67,701 in 1882-83. Including interest payable to the Imperial revenue (Rs. 21,60,758) and other charges, the deficit of the year amounts to Rs. 21,10,285.

.

FROM a report on arboriculture in the Hyderabad Assigned Districts for the past official year, we find that twenty-two public gardens and nurseries were maintained from local funds during the year. Of these, six are at district head-quarters, and are managed by or under the supervision of Deputy Commissioners, one at Chikalda, and the remainder at tehsil head-quarters. The total expenditure during the year amounted to Rs. 14,519, against Rs. 14,844 in the previous year. The results of the year's operations were not, on the whole, favourable, owing to the excessive rain-fall. On the 1st and 2nd July 1883, a severe storm of wind and rain caused considerable damage throughout the province; the rain-fall in those two days amounting to 8 inches 25 cents. The garden at Amraoti, situated in the bed of an old tank, was partly flooded for several days, and so much of the subsoil drainage of the higher ground to the south of the garden gravitated through the soil that the seedlings rotted off. The seeds of vegetables and other saleable produce had to be resown, and the late second sowing was not productive of a large crop. Then again, though the rain-fall in the year was 54 inches 77 cents, the heaviest on record at Amraoti, the wells in the Government garden failed in January, and some of the late crops suffered in consequence. The garden at Booldana had a narrow escape from being washed away as the tank above it overflowed, and the bund was injured. Fortunately the rain ceased just in time to prevent the bund being breached. The retaining wall of the tank has since been raised, and the tank is now safe. Considerable injury was also caused to trees planted in avenues and groves.

Among the trees destroyed were some fine cork trees in the avenue at Ellichpore which were uprooted by the high wind. Some of these were cut short, and put back in their places, and are doing well.

.

Of the 6,128 seedlings supplied for planting during the year, 2,505 were granted free to cultivators, and the rest were planted in weekly bazaars and along roads leading to towns and villages, in most instances to fill up vacancies. The principal trees planted were mango, jamoon, nim, and chinchwa, while those distributed to private individuals were guava, orange, and sweet-lime. With the exception of Akola and Basim, in which districts trees on new lengths of roads were planted, in other districts attention seems to have been confined to the maintenance of the existing avenues. The returns show that at the close of the year there were 63½ miles of avenue planted requiring no care or expenditure, and 71½ miles under care and involving cost. Eight new groves were planted during the year in the Amraoti and Akola districts. In other districts operations were directed rather towards maintaining existing groves than to planting fresh ones. There were at the close of the year 17 groves in encamping grounds and 226 groves in other places: the total area of the groves being 508 acres, 14 guntas. Almost every weekly bazaar site in the province is now provided with a grove of trees. These groves are placed in charge of the local committees of the places where they exist, and all expenditure in connection with them is incurred through these local bodies.

.

A LARGE number of trees are planted yearly by cultivators and others. The increase in the number of mango trees is most marked, especially about Akot and the villages under the Satpura range. In the Booldana district the owner of the site forming the encamping ground at Chikhli preferred to plant some trees on it himself, rather than to allow the Deputy Commissioner to do so, as he wished to mark his rights over the ground they were to stand in. No experiments in new kinds of trees were made during the year. Some Japan pea seed was put down in the Amraoti and Akola gardens, but the unusually heavy rains greatly affected the yield. The experiment will be repeated during the current year. Of the foreign trees planted in previous years, the *figus elastica* in the Ellichpore Government garden is making good growth. At Chikahda, in the gardens there, it is well established. The Australian oaks are this year doing well in Ellichpore, and the *pithecolobium saman*, or rain-tree, is growing vigorously. The carob tree grows well in the Booldana garden.

.

AN experiment, in the direction of introducing coffee cultivation into Assam, is being tried in the Nowgong district, where Mr. C. A. B. Anderson has obtained grants of two plots of land, measuring 685½ acres. As regards the success of his undertaking, Mr. Anderson lately furnished the following note to the Chief Commissioner: "I have 100 acres of coffee plants put out, mixed Arabian and Liberian. The former appears to thrive far better than the latter, which I have given up planting. I have large nurseries of Arabian seed in, for future extensions, and a small nursery bed of Maragogipe coffee from Brazil. I imported 100 Tamil coolies from an estate in Ceylon. The mortality was very high last year, but they are now thoroughly acclimatised, and work well. The land is granted on specially favourable terms by Government, the venture being the first hereabouts. I have planted a few rubber trees and also some cinchona, all of which appear to thrive well. The land is from 300 to 2,800 feet above sea level."

.

A CAYLON paper says:—"Our estimate framed early in October for the exports of season 1884-5 was 385,000 cwt. (against 360,000 cwt. given two months later by our daily contemporary); but from all we learn now, we doubt if more than 320,000 cwt. will be made up. On the other hand, it is very certain that of cinchona bark, we have still such reserves, that if the price continues encouraging, we can ship during the present season a good deal more than we ventured to estimate. The scare which arose over cacao, in connection with the effects of drought, want of shade, and of *Helopeltis* during the early and

middle part of 1884, has nearly died out, and the plantations well established in the Kandy and Matale districts are recognized as permanent investments of value."

.

THE value of Indian statistics, says the *Pioneer*, may be estimated by a glance at the tabular statement published in the last local *Gazette* of the deaths registered within the limits of the larger municipalities in the N.-W. Provinces during the week ending the 14th of January. Here we find, for example, Allahabad with a population of over 150,000 registering only 12 deaths, all causes included, during the week. This gives a death-rate of only 4 per annum for every 1,000 of population, men, women, children, and infants all included; so that each individual in this favoured spot has the average prospect of attaining the ripe old age of 250 years. If this be the nature of the statistics relating to "the larger municipalities," what value may be attached to those of the smaller municipalities, and what to those of the country villages which have not the advantage of supervision under the keen eye of the Municipal Commissioner?

.

A LAND question is engaging the attention of planters and other landholders in the Wynad. The Government is organising a re-settlement of revenue, and at a meeting held at Vythery, Mr. Castle Stuart, Special Assistant Collector, Nilgiris and Malabar, attended to explain the intentions of the authorities. He pointed out that the settlement would be for 30 years, and all lands capable of cultivation, though yielding no revenue to the occupants, will have to pay tax. The rates of assessment are not yet fixed, but probably will be settled within the next six weeks. Partial abandonment of estates after the re-settlement will not be permitted; the whole of the land will be subjected to assessment, whether any portion be abandoned or not. The meeting thanked Mr. Stuart for his information, and passed resolutions thereon, representing to the Government that "the existing rates of taxation are as heavy as can possibly be borne in the present state of extreme depression," and deprecating any action that would tend to increase their burdens until the views of the planters and landholders can be laid before Government. A Committee was appointed to draw up a memorial to his Excellency the Governor of Madras in Council, showing how the proposed taxation may affect European planters injuriously.

.

UNLIKE planters in Ceylon, the owners and managers of coffee estates in Java do not care to ventilate their troubles in the columns of newspapers, and thus it happens that we at a distance know little or nothing of the spread there of the dire pest, leaf-disease. Two years ago we heard of it incidentally, and we knew that a reward had been offered for the discovery of a remedy; but from that time nothing has appeared in the Java papers. We are assured, however, that, for all this reticence, the disease is committing sad havoc on most estates, causing a great deal of anxiety to estate owners. What steps, if any, have been taken to check the pest we have not heard, but private advices allude to it very despondingly, the more so that the other great Java industry—sugar—is suffering from low prices.

.

WE have to thank the Government of New Zealand for the annual Blue Book on the statistics of the Colony for the year 1883. It has reached us too late to give an exhaustive review of its contents. We will take an early opportunity of doing so. In the meantime we have much pleasure in producing a summary of statistics in a few articles of export:—The quantity of wool exported from the colony during 1883 amounted to 68,149,430 lbs., valued at £3,014,211. The quantity exported is in excess of that for the year 1882 by 2,826,722 lbs. The export of wool has greatly increased during the ten years ending December, 1883:—

	Wool exported.			
	lb.			
1883	68,149,430
1874	46,848,736
Increase for ten years				21,300,695

As remarked by the Registrar-General in the previous report, "the annual production of wool is better estimated by a statement of the exports for the twelve months ending the 30th September, that is, immediately preceding the commencement of shearing." The exports for the last ten years, ending respectively on the 30th September, are accordingly given :—

		Wool exported.
		lb.
1874	...	46,498,782
1875	...	49,942,148
1876	...	56,624,304
1877	...	56,521,278
1878	...	62,166,251
1879	...	62,614,497
1880	...	62,586,189
1881	...	60,477,151
1882	...	64,402,712
1883	...	71,842,949

But, in addition to the wool exported, a large quantity of that produced in the colony is now utilized at the woollen manufactories. It has been estimated that 1,000,000lbs. were taken for consumption by the mills in the year 1883, so that the actual produce of wool in New Zealand for the year 1883 may be stated in round numbers at 73,750,000lbs.

* *

The value of the wheat exported in 1883, as shown above, exceeded the value for the previous year by the large amount of £331,085. The increase in the quantity exported was 1,708,919 bushels, or 54 per cent. The value of oats exported in 1883 was greater than that for 1882 by the sum of £32,387. The increase in the quantity exported was 640,080 bushels, or 65 per cent. The quantity of wheat exported in 1883 was 4,897,540 bushels, and of oats 1,619,764 bushels. Ten years previously (1874) the export of wheat amounted only to 933,314 bushels, and that of oats to 135,959 bushels. The quantity of gold actually exported from New Zealand during 1883 amounted to 222,899oz., valued at £892,445. The export of gold has fallen steadily since the year 1880, when the value amounted to £1,220,263. In the year 1874 the export was £1,505,331. The value of gold entered for duty for exportation during the years 1882 and 1883, shown according to the districts in which produced, will be found in subjoined table :—

Produce of the Gold Fields in the Districts of—	1883.	1882.	Increase or Decrease.
	£	£	£
Auckland	163,618	131,007	Increase 32,611
Wellington	...	37	Decrease 37
Marlborough	2,524	5,400	" 2,876
Nelson and Westland	474,876	31,472	" 57,596
Otago	352,334	333,804	Increase 18,530
Totals	993,352	1,002,720	Decrease 9,368

The total quantity of gold entered for duty for exportation from New Zealand up to the 31st December, 1883, amounted to 10,322,333oz., valued at £40,457,495.

* *

MORE kauri gum was exported from New Zealand in 1883 than during any previous year. The quantity exceeded that exported in 1882 by 985 tons. Taking the different exports in order according to the total value of each, that of kauri gum (£336,606) stands for 1883 as fourth in importance. The tallow exported in 1883 is shown to have been £67,619 in value over that exported in 1882. The increase in quantity exported was 32,405 cwt., or 29 per cent. The timber exported in 1883 was valued at £149,256; the export for 1882 amounted to £114,700; but in 1881 the export only amounted to £71,328; so that a considerable development of this industry has recently taken place. In 1874 the export was only £44,450. The expansion of the Frozen Meat trade in 1883 was marked. The value of the exports for 1882, 1883, and the March and June quarters of 1884, are quoted :—

	Cwt.	£
1882	15,214	19,339
1883	87,975	118,328
March and June quarters, 1884	182,087	183,113

The rabbit-skins were exported in 1883 to the large number of 9,891,805. Ten years previously the number exported was 56,504. The value for the year 1883 being £100,955, this

article of export stands ninth in order of importance. The figures in the table above shows considerable development under the heads—hops, grass seed, and preserved meats. The value of the exports from each of certain ports for the years 1883 and 1882 is given for purposes of comparison :—

Principal Ports.	1883.	1882.	Increase	Decrease.
Lyttelton	£1,944,035	£1,655,005	£289,030	
Dunedin	1,789,857	1,701,300	88,557	
Auckland	1,067,816	975,361	92,455	
Wellington	1,027,816	782,527	245,289	
Napier	481,009	624,002		£142,913
Invercargill and Bluff	311,285	355,098		43,813
Timaru	237,000	111,161	125,839	
Oamaru	87,649	100,527		12,878
Kaipara	58,512	62,789	4,277	
Poverty Bay	32,637	21,550	11,087	
Greymouth	8,919	183,100		174,181
Hokitika	919	67,660		66,741

The total trade of New Zealand for the year 1883 amounted to £15,070,037, or £28 9s. 5d. per head of the mean population, exclusive of Maoris. If the Maoris (according to their number in the year 1881, 44,097 persons) be included in the population of the colony, and assumed to be consumers of imported articles to the same extent as Europeans, the trade per head of population will be found to amount to £27 6s. 4d. Doubtless they actually consume less, but any deduction on this account must be made on assumption, and vary according to opinion.

Review.

TEA-PLANTING IN CEYLON.*

II.

WE now come to that portion of "Eastward Ho's" pamphlet, which treats of the cultivation of Tea as an industry in the island. It need not surprise our readers to learn that there are ample proofs to show that Ceylon is unquestionably the tea-planters' "El Dorado" of the future. The profits that are steadily being realised, the opportunities offered for investment of capital in this enterprise, and other indications of a prosperous speculation—all point to the conclusion that before long, as regards the existing tea-producing countries, the first place must be conceded to her. To give an idea of what may be expected from the industry in Ceylon, and the position it is likely to attain to, our author has appended two communications which have recently appeared on the subject in the local papers. They are thoughtfully and carefully written by two gentlemen, whose connection with tea-planting render their utterances of great value. Mr. Armstrong's interesting paper was read before an appreciative audience, composed of the members of the Dikoya Planters' Association. He has given, so to speak, broad directions in the management of a garden from the time the seed is put into the ground, up to the time it is packed for export. According to this authority, tea will grow from almost sea level to over 6,000 ft., provided the soil and aspect are suitable.

Speaking of the former, he says :—"It should be fairly good—the richer the better—deep and friable, loam well mixed with sand. A shallow quartz soil is not good. Tea will not flush readily in this, although it may grow to a fair-sized bush. A subsoil, well mixed with sand, or grit, without showing a very good surface soil, will, although giving a slower growth at first, turn out a better paying soil than one with a rich surface and clearly defined clayey subsoil without an admixture of sand; the more we pluck, the deeper the roots must go, and we must have room for them. The higher our elevation, the richer should our soil be to make up for climate.

The higher the elevation, the less rainfall is required, and vice versa. Light showers, alternating with sun, if we could order them so would give us 1,000 lbs. an acre at 5,000 feet elevation. At the higher elevations, continued rain at the height of the monsoon has the same effect in checking the flush, for the time being, as a long continuance of sun has in the low country. Perhaps a good thing; for with us the

* Tea-Planting in Ceylon with other items. By "Eastward Ho." Colombo: Printed at the "Times of Ceylon" Press.

bush has no wintering, and the only rest, that of a 10lb. plucking, instead of a 24lb."

In the matter of seed he says:—"The greatest care must be taken to ascertain that the seed you obtain is from the highest class hybrid, as, with a poor jât, neither care in the manufacture or cultivation can make a good liquoring tea, or give a profitable yield. Making allowances for poor plants, accidents, bad plants, and the having ample plants over for supplies, I calculate on the maund of 82 lbs. for 6 acres planted 4 + 4; a maund of locally-grown gives from 27,000 to 33,000 seed according to the time that is allowed to elapse in weighing after husking; the sooner the seed is in the ground after gathering, the better."

As regards "plucking," he considers it a most important work which requires close supervision. It can be begun at 30 to 40 days after light pruning, and should not be begun till "the bud with opened leaf attached, and half the next leaf, can be plucked at one operation, leaving on one, or sometimes two, fully-formed leaves to carry on the young shoot. The shoulder of the half leaf plucked remains on, and protects the eye at its base, which in its turn throws out a shoot. Shoots, according to elevation, will measure 6 in. to 9 in. long before the first plucking, after pruning takes place. In after-plucking, a good deal depends on the number of leaves on the shoot. If, with the bud and its partially opened leaf, we have four full leaves, then I should pluck at the second leaf down (leaving on the shoulder of this leaf, which protects its bud, and will probably give red leaf if removed) at one operation, and again half the third leaf at another operation, leaving one fully formed young leaf on the shoot. Towards the end of the season, when the bushes are well up, I would act as above, only plucking at the third leaf, leaving its shoulder on the stem, and thus removing at one operation a half leaf and the shoot consisting of two leaves and the bud. One simple rule in plucking is, to avoid leaving a bare shoot without a single leaf to help it on. As in most things, a practical lesson is best in plucking. As for the number of days in which it is necessary to go round the garden, I learn, at a low elevation, it is considered necessary, according to the time of year, to get round in 7 to 10, up to 12 days at the longest. At high elevations I have found in my best months, I should get round in 10 or 12 days to keep pace with my flush, and, again in 15 to (in the very cold weather, December to January) 20 days. I do not think any hard-and-fast rule should be laid down, at any elevation, as to time. It is for the manager to watch his flush, and wait on it, just long enough, but no longer; and not to rush violently round his estate in a given number of days, which must lead to over-plucking, which means a reduction in yield sooner or later, although, perhaps, higher prices, for the time being. The benefit of tins is also in a way nullified by a smaller out-turn."

We regret that want of space prevents our following more closely Mr. Armstrong's directions in staking, topping, rolling, fermenting, and packing tea; suffice it to say, that those who are engaged in its cultivation, should consult the pages of the pamphlet for such useful and valuable information as it is likely to give. Before closing our review of this interesting work, we would reproduce a few figures from the prospectus of the Ceylon Tea Estate Company, Limited, which is embodied in it. Expenditure estimated for the first year for 500 acres of land is given at Rs. 36,450; for the second year, Rs. 23,650, with an additional 150 acres opened out during the latter period; expenditure during the third year, Rs. 26,490; making a total of Rs. 86,590, to bring the whole land into bearing. Out of this, deduct for 20 acres of forest land purchased, but not opened, Rs. 6,000; cost of open land, Rs. 80,580; cost per acre, Rs. 268 per acre of cultivated ground. The remaining 200 acres of forest will be left for firewood, grass fields, for feeding manuring cattle, and on ridges for burnt earth for manuring. Against this must be set crop picked during third year, from 150 acres, at 100lbs per acre, 15,000lbs. tea, at 60 cents, Rs. 9,000, which, as all expenditure is provided for, would pay ten per cent on capital. In this progressive way, the calculation is made to the end of the sixth year, when there is shown a profit of Rs. 34,950, or 40 per cent on the capital raised.

Miscellaneous Items.

A CENSUS of Simla will be taken during the present "season." It is some years since the last census was taken.

A SPECIES of wild potato has been discovered in the mountains of Arizona. The vegetable is about the size of a walnut.

THE American Anthracite Coal Companies have resolved to limit their output during the current year to 30,000,000 tons.

THE Sultan of Pahang has presented the Government of Victoria with a tin alligator moulded from tin found in that state. His object is to show the resources of his country.

THE number of steam and water mills for dressing grain in New South Wales is 154, representing 2,847 horse power, the number of hands employed being 685.

SOME one in Madras has made up his mind to compete with Chittagong in supplying Rangoon with eggs, and has just sent over a first consignment of 18,000,—rather late for the elections.

MR. JOHN MARSHALL, having resigned the chairmanship of the Bombay Cotton Trades' Association, the deputy chairman, Mr. Cassels, has been elected chairman, and Mr. Glacie deputy chairman.

THE trade in salt in Burmah has been unusually large lately; the imports from April to December were 1,159,253 maunds, against 888,807 maunds during the same months of 1883. The exports to Upper Burmah were 858,031 maunds against 292,322 maunds.

OWING to railway communication with Pondicherry not being resumed yet, since the recent heavy branches on the line, the Madras Salt Department is forwarding by sea a large quantity of salt required at Pondicherry. About seven hundred tons of salt are now being shipped in the ship *Soteria* to be conveyed to that port.

THE Pondicherry harbour project seems likely to go ahead. A party of engineers were engaged last week in surveying and taking levels at the eastern or Pondicherry end of the proposed works. We believe it forms part of the scheme of the Franco-Indian Coal Mining Company, which has already obtained valuable concessions from the French Government.

A CONFERENCE in connection with the Industrial Remuneration Trust, for the discussion of the labour question, was to be held in the Prince's Hall, Piccadilly, on the 28th, 29th, and 30th instant. Sir Charles Dilke was to act as president, and Mr. Shaw-Lefevre as vice-president; and 120 associates of a political and social character was to be represented by delegates at the conference.

THE Japanese begin to grow alarmed, says the local *Mail*, of the 9th ultimo, about the constant recurrence of earthquakes. They recall how the great catastrophe, more than a quarter of a century ago, when Yedo found itself one morning, surveying its own ruins, was preceded by a succession of petty, premonitory shocks, precisely similar to those recently experienced.

SIX petitions from agricultural associations in favour of protective duties on farm products have been referred by Prince Bismarck to the Federal Council. They demand that the duties on corn, cattle, and wool be increased fourfold, and that the gold standard be abolished. The decision of the Federal Council with regard to these propositions is awaited with much interest.

THE College of Science Geological Excursion Party started for Kattywar on Wednesday by the Bhownugger steamer. The party consists of forty students under Dr. T. Cooke, the Principal, and Messrs. S. Cooke, Page, and Moss. They will be the guests of the Thakore Sahib during their stay at Bhownugger. After a visit to Gogo and Perim Island they go to Joonaghur and the Palitana States, and return to Poona by about the beginning of next month.

OR late a new article of commerce appears to have come into demand in Bangalore, and promises to be a lucrative trade while the season lasts. The article is the rind of the orange, which is now being purchased, from those who collect it in the streets, at Rs. 2-8 a maund. We believe the skins are sent down to a Madras firm, but for what purpose has not been ascertained. Probably the rind is used for the purpose of extracting the essential oil it contains.

MESSRS. B. F. WILLECKE & Co., of Bombay, have just introduced into India a preparation, which they claim not only preserves wood, leather, paper, &c., from the attacks of white-ants, but guards them against dry rot, fungi, and other climatic influences. Since the substance has been advertised numerous enquiries have been made regarding it, and we understand that it has been successfully employed by firms who suffer great loss annually from the raids of white-ants. If Anti-Merulion possesses a tithe of the virtues claimed for it, we have no doubt it will command a large sale in this country.

AN agricultural exhibition is to be held at Nariad under the patronage of H.E. the Governor, H. H. the Gaekwar, and H.H. the Nawab Sahib of Cambay, in the early part of March. The show will be divided into two sections—one for cattle and the other for agricultural produce, and each section will be subdivided into various classes. The prizes for cattle will amount to Rs. 450 and for agricultural produce to Rs. 850. A strong committee has been appointed with Mr. Spry as president.

THE present condition of Mysore is such as to cause anxiety, the anticipations of scarcity and dearth of grain-stuffs having begun to be realized. The country is drying-up fast, and the outlook is, in consequence, gloomy, for we cannot expect rains for five or six months, and if last year be any criterion of this, it will be eight months before the province will be refreshed with rain. The gram crops are fair, but as other food grains are scarce, gram will, we may be sure, be also dear.

AN interesting report submitted to Government by the Director of Revenue Settlement, Madras, shows that out of a total area capable of being irrigated, throughout the whole Presidency, of 5,039,093 acres, 4,712,932 acres, or 92.5 per cent, are occupied and yield a revenue (exclusive of remissions) of Rs. 2,19,50,818, which is an average of 4.65 rupees per acre, of which, speaking roughly, 25 per cent, or 1.16 rupees per acre, represents the land tax, and 75 per cent, or 3.48 rupees per acre, the charge for water.

Two numerously signed petitions have been forwarded by the Indian residents of Singapore and Penang, against the Indian Immigration Ordinance V. of 1884. The Singapore petition, which was signed by over 1,200 Indian subjects, is addressed to the Secretary of State for the Colonies; the Penang petition signed by nearly 1,000 Indian subjects unconnected with agricultural labour, is addressed to the Governor of Madras in Council, but copies of it were also forwarded to the Viceroy and to the Secretary of State for the Colonies.

THE trade in rice and paddy with Upper Burmah shows an enormous increase—in fact, it has more than doubled. The following are the figures for the nine months:—In 1883, rice, 270,513 maunds; in 1884, 950,868 maunds. Paddy, in 1883, 661,360 maunds; in 1884, maunds 1,020,335; total for 1883, 931,873 maunds, and total for 1884 1,980,203 maunds. This result is partly due to a very bad harvest last year, and partly to a reduction of the area of cultivation, in consequence of the misgovernment of King Theebaw having driven so many of the cultivators out of the country.

A SERIES of tables showing the extent in statute acres and the produce of the crops for the year 1884 in Ireland was issued lately. The total extent of land under crops was 4,872,744 acres, of which 1,962,487 consisted of meadow and clover, 1,348,444 of oats, 798,952 of potatoes and the remainder of wheat, barley, rye, beans, peas, turnips, wauzel, beet, carrots, parsnips, cabbage, vetches, flax and rape. The amount of meadow hay and clover produced was 3,822,775 tons; potatoes, 3,040,352 tons; turnips, 3,507,924 tons; oats, 18,109,418 cwt.; wheat, 991,654 cwt.; barley, 2,675,789, and flax, 2,505,850.

THE Ceylon Planters' Association has resolved—"That this Association emphatically protests against any increased burden of taxation, both because the planting community is suffering from severe depression owing to the partial failure of the chief industry of the colony, namely, coffee; and because it considers that the funds so raised are not necessary for the development of the resources of the country;" and "That in the opinion of this Association the policy of attempting to restore large irrigation works has no justification, and is the main reason for an unnecessary increase of taxation."

THE plan of compressing green fodder in stacks above ground, instead of in silos, long practised to some extent by Dutch farmers, has been tried in England during the past season. A Hampshire farmer reports a successful experiment of the kind. He carted some grass as soon as it was cut, stacked it in the ordinary way, and weighted it every evening with about two tons of railway metals, of greater length than the width of the stack, which was nine yards long and five yards wide. By this means a large quantity of grass was compressed into a small space. When the stack was finished, the loose grass from the side was pulled out and put on the top, which was not thatched. The result is about 50 tons of very good fodder, similar to silage. There is some waste at the sides and on the top, but not more, it is said, than is commonly found in silos.

THE young Nawab of Mamdot is to be congratulated on the annual horse show at Jellalabad. This year, nearly three hundred animals were exhibited, and Rs. 600 was given away in prizes by the Government,—exclusive of the amount given by the Nawab out of his private purse. A native correspondent writes that, at the conclusion of the show, the Nawab was decorated by Colonel Corbyn, Deputy Commissioner, with a silver medal, as an acknowledgment from the Government of the young Chief's energy in starting so valuable an institution. In returning thanks for the honour, the Nawab expressed his gratitude to Colonel Gray, C.S.I., under whose charge he had been during his minority. Some eight or ten military officers were entertained at Jellalabad by the Nawab; and it is almost unnecessary to say, that sports of all kinds were organised for the occasion. A polo match between the Nawab's team and some officers of the 30th Regiment, resulted in a victory for the former.

Selections.

THE FOOD CROPS OF MEXICO.

THE great cereals of Mexico are maize or Indian corn, wheat, and barley. The extraordinary fecundity of the maize, ranging as high as four hundred to one, in spite of the lax and rude agriculture, makes it the foremost crop in our sister Republic. Its value in 1883 is given at \$114,165,290; that of wheat is stated at \$17,598,890; while barley (grown chiefly on the higher portions of the eastern table-lands of the Sierra Madre) is put at \$4,603,770. Corn is produced in every one of the twenty-nine political divisions of the Mexican Republic, though its largest growth is found in the States of Jalisco, Guanajuato, Mexico, Oajaca, Michoacan, Puebla, Vera Cruz, San Luis Potosi, Zacatecas, Yucatan and Hidalgo, wherein the annual value of the crop, as named, ranges from about \$17,000,000 down to about \$4,000,000. These eleven States are, with the exception of Vera Cruz and Yucatan, mainly included within that favored portion of the southern table-land, which, while designated as the *tierra templada* (temperate earth), yields equally of tropical and temperate products. The annual product of the States of Guerrero, Nuevo Leon, Durango, Sinaloa, Morelos, Tamaulipas, Tlascala, Chihuahua, Queretaro, Sonora, Tabasco, Coahuila, Chiapas, and probably Aguas Calientes, ranges from over \$3,000,000 down a little less than a million.

Wheat grows on the plateau of Mexico at from 6,000 to 9,000 feet above sea-level, and between the eighteenth and twenty-fourth parallels of latitude. Corn grows everywhere, except on certain waste districts along the frontier, where the soil is the same as the arid plains of Arizona and New Mexico. The wheat-growing area of Mexico, *par excellence*, extends, from, say, Puebla nearly to Colima, about 500 miles east and west, and from Southern Michoacan to Southern and Central Chihuahua, about 500 miles north and south. This plateau is broken by mountain ranges into a number of rich districts specially adapted to the growing of wheat, and of this immense field of rich and arable land one-third, it is believed, could be readily put into wheat with due regard to all other agricultural interests. Under the Mexican plan of cultivation three crops are taken off the land every two years—one crop of wheat and two crops of corn. The average yield of wheat of Mexico does not now exceed 20 bushels to the acre. Corn on irrigated lands runs about 50; on dry land about 30 bushels to the acre. The mode of cultivation is similar to that of the Egyptians thousands of years ago. Wooden-beam ploughs are used, with a small iron shoe, which scratches a furrow 5 inches broad by 5 deep. Five men are used and five yoke of oxen where one would be needed in Pennsylvania. Nevertheless, the grain is of the very finest quality, and at the Centennial Exhibition, Mexico took the first prize, leading the world in wheat, as in coffee. Thrashing is done as in the olden way, on a hard floor, in the open air, and by driving mares over the wheat. The grain is winnowed by men tossing it into the air with large scoop shovels, thus imperfectly separating the chaff. The grain is then taken from the thrashing floor to the granaries or railway depot in ponderous and rudely constructed two-wheeled ox-carts, creaking at every turn. There is more cart than grain in the load pulled by the patient oxen. Already, however, there are marked changes in this primitive method, with its quaint aspects, so suggestive of oriental life and Biblical descriptions. American implements and machinery are going in rapidly, and the only danger is that the large land-owners may push the changes required too rapidly for the immediate welfare of the laborers of the country.

Rice is also an indigenous product of Mexico. But little attention has been given to its cultivation until within a year or two past. Some part of the crop is exported, and meets approval. There are large areas in the lower States where the cultivation of rice could be made profitable.

Potatoes are indigenous to Mexico, and are still found growing wild as far north as the table-land or mesas of Southern Arizona. The yield is large, but is not sufficient for the wants of the country. As to barley, it is a grain of the higher region, and grows well at a surprising altitude. Dr. Oswald, in his "Summer Land," describes Indian villages on the lofty table-lands of the west or Pacific coast, who raise barley as their grain; some wheat is also grown on them.

"Chili" (*capsicum*), the Mexican pepper, is of great importance to the Mexican cuisine, and supplying to the people that food stimulus which seems to be so necessary in warm, dry climates. Its production is as general as that of corn. Its annual production is quite large, and with the improved industrial condition accompanying and following the railroad construction, and all related movements of production and commerce, will be sure to greatly increase. The exportation is small. It is thus described by the British minister, Mr. Ward, in 1827:

"Whole estates are devoted, on the table-land, to the cultivation of this most powerful stimulant, and few are more productive, as it constitutes one of the necessities of life with the Indian and mestizo population, and is used in very large quantities at the tables of the creoles of all ranks. Its pungency is so great that amongst the uninitiated, it produces absolute excoarication; but the palate becomes accustomed to it by degrees, and habit renders it indispensable. It is used by the lower classes as a seasoning to the insipid tortilla, and the two together furnish a meal which they would not exchange for an allowance of meat and wheaten bread."

The plough in common use in Mexico consists of two poles, one 6 feet long and the other 15 feet, fastened together by a mortise and tenon at an angle of 65°. Through and near the end of a short pole, there is a pin to steady the plough, and on its end there is attached a pointed iron or steel shoe to prevent it from readily wearing out. The yoke has no bows, but is fastened on the heads of the cattle by means of raw hide thongs, and so is the tongue of

the plough to the yoke. With this rude implement the second soil is scratched to the surface of 3 inches. The molar and light farming tools used in this country were until very recently almost wholly unknown in Mexico. The machete (sugar-cane knife), clumsy hoes and spades, with a heavy sickle and pruning or cutting knife, constitute most of the farm tools used by the rustic "labores." Burdens are yet borne on the backs of men or women, as a rule; the barrow is a convenience still uncommon off the lines of railroad, and not common even there. The irrigation is largely regulated by manual labor. With the Mexican farmer ploughing for wheat begins in August, and lasts until he wants to stop. Wheat is sown broadcast from October 1 to January 15, and is harvested the following June. After the wheat is up, it looks as if it had been sown with a drill, owing to its having fallen into the furrow made by the plough. From one-third to one-half the wheat is lost by the primitive methods used in thrashing. The price of wheat (1883) per fanega (150 pounds) in our money was from \$2.75 to \$3. The first corn crop is prepared for in February and March; it is laid by in August, and gathered in December. The second crop is planted in June and July, laid by in August and September, and gathered in December and January. The reason why the second crop matures more rapidly than the preceding one is, because no irrigation is needed, the rainy season making it grow with great rapidity.

Tortillas, the common food of the country, are made by placing a quantity of maize in a jar of hot water and lime over-night. Great care is taken as to the quantity of lime to be used, as otherwise the grain will not be properly softened. In the morning, or when it is to be used, the grain is taken out of the jar and placed upon a small stone bench, at which a woman kneels, and then, with a long stone roller, reduces the grain to a kind of paste. When it has obtained the proper consistency, it is patted with the hand until it assumes the form of small pancakes, which are then slightly dried or baked on a large earthen tray or pan, over a small charcoal fire. The tortilla is made! Everybody eats them. Foreigners, especially Americans, find them detestable. Their preparation is a waste of labor and material both. It is fearful drudgery to the women; and whether so considered or not in Mexico, is to all others who take note of things there as they are, the outward and visible sign of the industrial and social degradation of the mass of women. The preparation of the tortilla takes up so much of their time that no proper care is taken of the dwelling, the children, or of themselves. Some Yankee inventor, who has seen the tortilla-making process, might readily devise a small and cheap machine by which the maize-paste, so much delighted in by the Mexicans, could be furnished to whole neighbourhoods. It is hardly possible to change their habits, and induce the use of ordinary corn-meal all at once or even extensively, yet it might be done in the cities, and be made a profitable venture for some enterprising person.

THE GREEN ALOE.

It does not fall to the fortune of everyone to secure good land, even in this favoured district, either through inexperience, or reposing too much confidence in others to select for them. To meet such cases of acquisition of poor land, and also for the utilisation of what is looked upon as useless land in rich sugar estates, I have decided to devote my remarks at present to the cultivation of a plant that will grow in almost any kind of soil and anywhere; but which flourishes more luxuriantly and profitably in a tropical climate. The plant I refer to is the Aloe, or rather that species of Aloe, for there are a great variety of Aloes, of the genus *Agave Fœtida* or *Fourcroya Gigantea*, commonly known as the Green Aloe. In Sicily the peasants have bestowed upon this plant the title of the "Farmer's friend," from the fact of it growing where nothing else could be reared, without any attention being given to its cultivation or outlay to enrich the soil by manuring. It is also untouched by change of weather, standing equally well wet or dry, and appearing to be proof against floods, hurricanes, or diseases of any kind whatever.

"The Green Aloe has a very short stem, bearing at its summit a crowded head of large fleshy leaves which are spiny at the margin. From the midst of these shoots up the straight, upright scape 24 ft. to 36 ft. high, and at the base often 1 foot in diameter, along which are small, appressed, lanceolate bracts, with a terminal panicle, often bearing as many as 4,000 small bulbs. In this climate, it flowers when about seven or eight years old, but in colder countries not until a very advanced age, whence arises the gardeners' fable of it only flowering once in a century. The leaves, which grow to a length of about 8 ft. reach their full development at the fifth year, so that four or five crops could be gathered before there is any necessity for replanting. When starting in the cultivation of the Green Aloe a fair soil may be selected, as giving rather better results than the extremely poor, though it will grow in any land. Soil being no desideratum, ordinary clearing is all that is necessary in preparing the field. The best time to plant is during the rainy season, but this is not absolutely necessary, as generally speaking, Aloes may be planted all the year round.

"The Green Aloe can be raised either from seed or by suckers, but the best method of propagating it has been found to be from the seed. The seeds, which take the form of bulbs or onions, and are borne on tall stems previously referred to should be sown in rows 10 inches apart and 6 inches from each other. When ready for transplanting they must be planted out into fields at a depth of 3 inches to 4 inches, leaving a clear space of at least 5 feet between each plant. If it should be found desirable, from any particular circumstance, to rear from suckers, this can be accomplished, from plants one, two, or three years old.

"The commercial value of this plant is derived from its leaves, which yield a strong fibre which is used in the manufacture

of rope, twine, hammocks, &c., and is generally known as Pita flax. Large quantities of it are grown in Sicily and Mauritius; in the latter country, in some instances, even canefields being turned over to its production.

"The plant yields its first crop in its fifth year, when the leaves must be gathered while green, as if allowed to grow yellow or ripen they become too woody, and the fibre loses strength thereby. To prepare it for market the fibre has to be separated from the pulp, and under the old style this was accomplished by maceration, but this process was soon abandoned from its many imperfections. Crushing the leaves by means of rollers to extract the juice and then separating the fibre from the pulp by hand was next resorted to, but this method was likewise found to be very defective on account of the rollers cutting and destroying a large quantity of fibre. The time and labour required was also a serious drawback.

"After many experiments a machine has, at length, been constructed which answers admirably the purpose for which it was invented. It consists of a wooden wheel 2 ft. in diameter, upon the surface of which are fixed 18 scratchers two inches long at a distance of two inches apart. The wheel is fitted on two trestles and can be worked by hand, horse, or steam power. Opposite the wheel is placed a strong, narrow table upon which is fixed a piece of hard wood, covered at its head with strong leather: this is called the counter-scraper, and is made to slide towards the wheel, being regulated by a screw which adjusts it firmly to the table at the required distance. The counter-scraper plays an important part in the process, and requires careful manipulation, that the fibre may neither be cut nor imperfectly cleared.

"In using the machine the operator charged with the work places the leaf between the scratcher and the counter-scraper, top foremost, and allows the pulp to be removed for about two-thirds of its length, when he turns it round and completes the operation from the other end. As soon as this operation is accomplished and the fibre freed from the pulp, it is well washed and dried in the sun, when it is ready for market. The use of iron in constructing this machine should be avoided as much as possible, the juice of the leaves being strongly impregnated with acidity, which rapidly corrodes and destroys that metal.

"The average yield from the cultivation of this plant is about a ton-and-a-half of dry fibre per acre; every 100 leaves giving about 3½ lbs. Now, as the market price in England is between £35 and £40 per ton, it does not require much calculation to arrive at the large profit there is attached to the cultivation of this plant, especially when the nature of the land upon which it can be produced is taken into consideration; the above figures representing the returns from poor land."—*Cairns Telegraph*.

On the same subject, a writer in the *Mackay* (Queensland) *Standard*, says—

"An industry which of late has found favour in several countries is the cultivation of the aloe. The beautiful fibre made from this plant has already been turned to several accounts by the manufacturer, but where it is especially valuable is in making cordage. Captain Pender, when making deep sea soundings between Mauritius and Reunion, and Reunion and the Cape, in 1876, with the view of laying a submarine cable, mentions in his report that the line which rendered him most service was one made in Mauritius from the aloe plant. The line was stronger yet much lighter than any he had taken with him, and was in every way better suited for the work he was engaged in. The kind of aloe most appreciated is that known by botanists by the name of *Fourcroya Gigantea*, but better known at the Cape as the "Yucca," or in Jamaica as "Adam's Needle." Within the last few years serious attention has been directed to this magnificent natural product, and several factories have been started for the extraction of the fibre from the green leaves. Till lately it has grown wild in Mauritius and Reunion, but since some bundles of fibre fetched as high as £35 per ton in the London market, an impetus to aloe growing has been given, which bids fair to make it, at no distant date, one of the principal exports of many countries which possess land too rocky and arid to admit of any other cultivation. Of late, with improved machinery, and greater care bestowed in washing and drying the fibre, as much as from £45 to £48 per ton has been obtained in the home market. It is but right, however, to say that this high price has fallen of late, and that the ruling price of first class fibre is from £32 to £36 per ton. The beauty of this plant is that it grows without cultivating; that is to say, once planted it requires no looking after to clean it, &c., and it will continue to give leaves for a number of years before it requires renewal. Drought has no effect on it, and it is of the hardest growth and grows beautifully in Mauritius and Reunion, in arid land that has been thrown out of sugarcane cultivation on account of drought. An acre well planted gives about 1½ tons, but this will go to 2 tons later, when better machinery is used for decortication.

"In the year 1871 the value of the plant exported from Mauritius was £280, while the quantity amounted to 8 tons. In 1880, 752 tons, worth £26,320, were exported.

"A few remarks on the planting of this long neglected but useful plant may prove interesting and perhaps profitable to some. When young plants of 18 months to 2 years' growth cannot be had, the seeds are planted. The soil is turned by the stroke of a hoe, and a seed put in and covered up—nature is left to do the rest, except in cases where the young plants are prevented from growing by creepers. When these prevent the young plant from growing they are weeded out. A space of about 5 feet by 4 is left between each plant, thus giving 2,000 plants to the acre. The right time to cut the leaf is when it changes slightly its colour, and becomes a lighter green, or according to the soil a yellowish hue. In damp places this change is not apparent, and a practised eye is required to tell the proper time to cut the leaves. Plants from seed take

4 or 5 years to come to maturity, the outer leaves may, however, be cut one year earlier; but in the case of young plants of 18 months to 2 years, from 2½ to 3 years must elapse before they can be cut. The time allowed to elapse after the first cutting is generally from 9 to 12 months, according to the vigour of the plant. The outer leaves are cut off close to the stem, leaving 4 or 5 round the heart. As each plant dies, it is left to enrich the soil and the numerous small seedlings that spring up around the roots of the parent stem. The surplus seeds have not been turned to any account yet, although lately a French chemist in Paris has extracted from them an essence which he asserts is excellent in fixing colours in prints. Experiments in this line are still being made to ascertain if it cannot be made to yield something else. The green pulp scraped off the leaves is also the subject of serious investigation at the present moment, both here and elsewhere.

"Another field of industry which is open, is to manufacture this pulp into paper in the colony. This plant could easily be made to grow around hedges, and thus the most could be made of land too valuable to be exclusively planted with aloes. A decorticating machine has just been patented in Mauritius for the extraction of this fibre."—*Paper Maker's Monthly Journal*.

TEA.

THE demand for Congous continues fairly good, and prices for all kinds remain firm. Although not quite so low as during the panic which prevailed a few weeks since, Congous generally are still much below the average of any recent year, and as supplies are ample, there is no reason to anticipate any marked improvement in values at present. Their cheapness has attracted an additional demand from the retail trade during the present month, and many of the larger dealers have bought very freely. With a continuance of low prices, which will probably ensure a large consumption, there is reason to expect a good general demand in the early part of next year. There has been some inquiry for the better grades of Black Leaf, several parcels of Oonfaah and Kintuck having changed hands at about previous prices. A few transactions are reported in first-crop Oonfaahs at from 9d. to 10½., and some second-crop Keemuns at similar prices have also been sold. The latter are now remarkably cheap, and are being freely used by the retail trade. Souchongs are not quite so plentiful as they were a few weeks ago, and show a decided recovery from the lowest point of the market. At the public sales of China Tea rather more than 29,000 packages were offered, without reserve; of these, 22,400 were Congous, chiefly common grades, all of which realised firm prices.

Fancy Teas show very little alteration, Canton Capers are perhaps slightly firmer, owing to the smallness of the supply. The finer kinds of Foochow Pekoes are also rather less plentiful. Few transactions have taken place in Oolong. Green Teas have been in better demand, and prices are slightly better for most Moyune kinds.

There has been a fair supply of Indian Tea, and prices generally are steady. The cheapness of Souchongs and Pekoe Souchongs has caused an active inquiry, and large transactions have taken place. As the market will probably be well supplied with these sorts in the early part of January from the large accumulating imports of the next fortnight, a continuance of the present low prices may be expected. Should this be the case a considerably increased demand may be anticipated, as these descriptions have fallen sufficiently to bring them into favourable competition with China Congous, thereby enabling retailers to use them liberally. Broken Teas under 1s. are more plentiful, and have met with a good inquiry. Although these descriptions show an important decline from the highest point, still lower prices may be looked for, judging from recent reports from Calcutta of the large percentage of very common Teas sold at recent auctions. For medium broken and whole-leaf kinds, there has been a good demand, the former fetching fully previous rates, but the latter are less firm. The values of the finer qualities are, however, well maintained. Ceylon Teas have sold readily, but the inquiry for Java descriptions is very limited. At the public sales, 16,005 packages of Indian, 476 Ceylon, and 812 Java Teas were offered; of these, 2,593 were withdrawn.

The arrivals for the week are:—The *Glengarry*, from Shanghai, Foochow, and Hong-Kong; *Astronomer*, City of Edinburgh, and *Chen Graham*, from Calcutta.

—*Produce Markets' Review*.]

SUGAR INDUSTRY IN THE PAST YEAR.

THE year which has just closed has been a most disastrous one to nearly every one—except retailers and consumers—interested in sugar. In no one year in the history of the trade have the losses all round been so enormous. The price of sugar at the commencement of the year was so low, that it was the opinion of many shrewd men in the trade that the bottom had been touched. Instead of this proving to be the case, the fall in values continued steadily, month by month, with scarcely a break, all through the year, until the price of beet 88%, which in January stood at 17s. 6½., fell to 10½., a difference of 42½% in the 12 months; and this, too, in the face of an increase in the world's consumption, which is without a parallel.

The cause of this serious fall in price is obvious;—over-production, brought about by the system of bounties, adopted by Germany and some of the other beet-growing countries, on their export of sugar. As we showed in the October *Sugar News*, page 546, the average bounty given by the German Government for the campaign 1883-84, was 2s. 8d. per cwt., and the line of argument adopted by the Board of Trade, is, that the bounty being only 2s. 8d., whilst the fall in value is 7s. 6½., the difference—4s. 10½. per cwt.—is due to the natural fluctuations of the market; apparently ignoring the fact that it is this bounty of 2s. 8d. per cwt. which has led to this excessive production, and is the cause of our present troubles.

If evidence were required to prove this, we have only to turn to France. In 1868-69 the French crop amounted for these two years to 501,000 tons. In 1875-76, when the bounties were in full force, the production rose to 913,000 tons. In the year following, measures were taken by the French Government which practically removed the bounties on production; from that time the crop has shown no increase, and the production of sugar has become so unprofitable, that the Government have been forced to pass a law, under which it is anticipated that a larger bounty will, in future, be obtained by the French growers, than by those of any other country in Europe.

This ought to be a conclusive answer to those who assert, on the one hand, that the fall in the price of sugar is not due wholly to the bounties, and, on the other, that if the bounty growing countries are left alone, the loss to the revenue will become so serious that they will, before long, be compelled to abolish the system.

The natural remedy for this, is the imposition of a countervailing duty. To countervail, is "to act against with equal force or power," to equal, to balance. A countervailing duty would simply be placing sugars upon a natural basis; and this is all that our sugar colonies ask should be done. If, all being equal, it is found that they cannot compete, they will accept the situation, and turn their estates to the cultivation of something else. Reasonable as this remedy is, and quite consistent with the principles of Free Trade, still the idea that a countervailing duty is only another name for Protection, has got hold of the public mind, who associate it with the mischievous Fair Trade movement, so that no Government, either Tory or Radical, would venture to adopt it. We must therefore, dismisse from our minds this mode of meeting the evil.

This being the case, we think Mr. Baden-Powell's proposal of calling a Conference of the different beet growing countries, with a view to put an end to the present "war of bounties," as set forth in his article, "A Last Word on the Bounty Question," re-printed in our last number, is the only one likely to effect the object.

Negotiations have recently been entered into between the United States and Spain, for a reciprocity treaty for Cuba and Porto Rico. The details are to be submitted to Congress at an early date. It is said to be the most complete reciprocity treaty ever negotiated by the United States Government, embracing not only the exchange of products, but also special shipping privileges for the vessels of the two nations, abolishing all tonnage and consular fees on vessels and cargoes, and making all other fees the same as for the national vessels engaged in the coasting trade. It also contains special privileges for commercial travellers, reforms in the Cuban customs regulations, concerning fines and the responsibility of vessels for errors, when fraud has not been proved, and a stipulation against the imposition of new import taxes. If this proposed treaty is carried into effect, which we think very doubtful, it means that one-half of the sugar now consumed in the States will be admitted duty free. Naturally we might conclude that this would be a boon to the consumer of sugar. Will it, however, prove so? Judging from the working of the Hawaiian Treaty, we doubt if the consumer is benefited one cent, notwithstanding the duty to be remitted would amount to something like £5,000,000. It is just the sort of "big thing" for such millionaires, as Vanderbilt, to handle and "control," and the plunder being shared in between them and the planters; they looking well to it that they secure the lion's portion. Then there is the matter of drawbacks; how is the distinction to be made between those sugars which have paid duty, and those admitted duty free? Would not this open a very wide door for frauds on an extensive scale?

What would permanently benefit the West Indies would be, a reduction of the duties, say to one-half, if the time has not arrived for their entire abolition. This would lead to a still further increase in the consumption in the States, and, as a consequence, in time, to a decided improvement in prices.

The severe crisis through which our West India colonies are passing, has led to a considerable correspondence in our daily and other papers, as to its causes, and the remedies to be applied. Our planters have been twitted for their want of skill and energy in the cultivation of the cane, and in the manufacture of their sugar, and in this respect showing the striking contrast

between them and their German rivals. We are far from saying that our planters have made the most of their opportunities, but in instituting contracts, to be fair, every circumstance should be brought into the reckoning. Their German rivals have given them the most powerful incentive to put forth their utmost energies, for every decima! percentage of sugar obtained beyond the legal yield, is a clear gain to them, to the extent of the duty. Our own planters have no such incentive, but, on the other hand, have been struggling on, handicapped by these bounties.

The British Refiners' Committee have been, during the year, in frequent correspondence with the Board of Trade and the Foreign Office on the question of Foreign bounties, more especially those of Holland and the United States. Mr. Duncan, as chairman of the committee, in his letter to Mr. Giffen, of 29th April, referring to Holland, concludes as follows:—"And now that my statements have been fully verified, in every respect, I cannot refrain from expressing my regret that the accuracy of my statements was disputed, and my warning disregarded, more especially as the competition of Dutch loaf sugar, at prices below the cost of production, has continued to increase, and has been most harassing to producers in this country."

The Refiners' Committee also pointed out to our Government, and, through it, to the authorities at Washington, that if the provisional arrangements in respect to drawbacks, under the New Tariff, became established, the American refiners would get a bounty on exportation of 2s. per cwt. Unfortunately for the refining interest of this country, these representations were unheeded; the consequence has been that during the first 11 months of 1884, more than 50,000 tons of refined sugar have been exported to this country, upon which the American refiner has received a bounty of upwards of £100,000—that is to say, the American Government have paid back, in the shape of drawbacks, £100,000 more than they have received in duties upon the sugars so shipped.

Mr. Giffen, in his summary of the report to the Board of Trade, points out, in order to show that the refining trade of this country cannot be an unprofitable one, that the present production of refined is as great as ever it was. It is well known that the cotton trade of Lancashire at the present time, is in a bad way, and yet the quantity of yarn and cloth now being turned out shows no diminution. Are we to infer from this that there is no real foundation for the complaints which we hear on all sides? The cotton spinner like the refiner, has heavy standing expenses which have to be met, whether the place is standing or working; and the question has sometimes to be decided, which is the less loss—to work, or to stand? Mr. Giffen would have the public to infer that because our refiners do not, one after another, close their works, that there is no ground for their grievance.

In entering upon a new year it is very natural for the mind to speculate upon the probable course of events. As regards sugar, at the present time, this is almost impossible to do as for a captain, when leaving Sandy Hook, to tell when his ship will arrive in Liverpool. At the same time, there are indications which may fairly furnish good ground for a more hopeful feeling. At a recent meeting at Halle, of German beet-growers and fabricants, it was unanimously decided to reduce the production by 20 per cent, as the only way by which such an improvement in prices could be brought about as would enable the fabricant to give to the beet grower a price that would pay him to go on cultivating. If this is done, it means a reduction, in the next campaign, in the German production of sugar of 200,000 tons, and if we take into consideration the increase that is going on in the consumption, a decided advance in value may fairly be looked for. One thing is very certain, that sugar cannot be grown and delivered in this market at anything like 10s. per cwt. It cannot be done in Germany, even with the bounty of 2s. 8d. per cwt., much less in our own colonies, with no bounties to help them out.

SUGAR.

THE raising of the previous estimates of the German Beet crop by 50,000 tons, though partly balanced by a reduction of 25,000 tons in the French crop, has increased the depression of the Raw market, and Beet has again declined in price. On the other hand, the total landings of all Sugars for the week ending 13th instant showed the large falling-off of 10,000 tons, by which the surplus in the stock at the four ports was produced to 28,000 tons; but this will be largely increased if the German fabricants find that it is hopeless to look for any permanent improvement in prices. At present they seem to prefer to warehouse their sugar, as the exports so far this season only show quite a small increase, notwithstanding the far larger crop. The general stock here will also be considerably enlarged by an expected increase of supplies from Java, which will probably more than balance any falling-off in shipments of refining sugars from the West Indies. The cane crops generally promise an unusually heavy yield. Only a small business has been done in the refining kinds here this week, but low brown Eastern Sugars have met with a fair inquiry. Crystallised Demerara has been freely offered, and as the present low prices have induced the trade to buy more freely, Yellow Sugars are fairly steady, but the paler sorts are somewhat cheaper. The quantity of crystallized raw sugar imported to London in the week ending 17th instant was 3,323 tons.

The demand from the trade for Centrifugals has been very small, but as the refiners have somewhat reduced their out-turn, Mediums are 3d. dearer. Other kinds are unchanged, except for the lowest Yellows, which are rather cheaper. The supply in the market will be further reduced during the next week or ten days, but it is to be hoped that after the holidays are over, business will not be checked by any limitation of work on the part of the refiners. Any effort to raise prices by artificial means would, even if tem-

porarily successful, only be followed by a heavier drop later on, in the present condition of the sugar market. Besides, a condition of the kind appears recently to have broken down on the Clyde, as the temptation of the existing margin was too great for the refiners there. Greenock is, in consequence, again heavily underselling London, and if our refiners combine to raise prices, they will simply drive the trade elsewhere. This would be the more regrettable as, if prices continue moderate, there is a prospect of a better demand from the grocers, who no doubt have lately been working with very small stocks. On the other hand, with the existing weakness in Beet root, were the prices of refiners to be forced up to any extent, a reaction would inevitably follow. Our refiners would again miss the chance of doing a good trade, they would have raised the price of Beet upon themselves, and would be forced to buy, at a higher price, sugar which, by the time it was made, would have to be forced off in a rapidly falling market. Surely after the experience of the past the recurrence of such a state of things is to be avoided by refiners and dealers alike. As regards the lower Centrifugals also, it is well to bear in mind that Demeraras of far superior quality can now be retailed profitably at 2d. per lb. English Titlers and Dutch Loaves are again 3d. cheaper, and contracts for delivery up to next March have been made for the latter at the present low rates. Cut sugars are unchanged, and are selling slowly.

The following Greenock market report is dated December 18th:—"We have had a rather dull week, buyers shy, and disposed to hold off unless at a decline. The amount of business done has been much less than in any very recent week, and prices have tended distinctly against sellers, showing a rather irregular 6d. to 1s. since Thursday last. Supplies are larger. Deliveries scarcely satisfactory in view of increased quantities on offer." The following Greenock telegram reports Friday's market:—"Good business done at easy prices."

It is curious to notice that the imports of sugar from Europe into the United States amounted, from the 1st January to the 4th December this year, to 70,000 tons, and that the exports of refined sugar from that country, chiefly to United Kingdom, reached 58,195 tons in the same year. This apparently absurd journeying backward of sugar over the Atlantic, is effected at the cost of the tax-payers of the United States, who, in addition to limiting their consumption by import duties, grant heavy export bounties of certainly £2 per ton to their refiners. The latter, in consequence, are in a position to buy sugar in Europe, bring it over thousands of miles of sea, and then send it back again the same distance, and yet under-sell the British refiners in this market. In short, our Yankee cousins pay some £100,000 a year in unnecessary sugar duties, in order that we may have fractionally cheaper sugar. This may be an excellent system for the New York and Boston refiner, but the outness of the tax-payers in the transaction is by no means obvious. No doubt, as a matter of fact, they are ignorant of the whole affair. A round-robin, signed by our refiners, explaining the case, and inserted in all the trade and leading political journals of the State, would probably upset the system. Even as an advertisement it would doubtless attract much attention. According to the reports in our newspapers, the treaty admitting Spanish Colonial sugar free into the States is likely to be rejected by the Washington Senate. No fresh news has been published as to the progress of the Sugars of our West Indian Colonies.

The following return of the exports of sugar from Germany in the first eleven months of the year, shows that the low prices and the great difference between the market value of Raw and White Sugars, coupled with the far heavier drawbacks on the latter, are causes tending to make the manufacturers produce sugar fit for consumption without refining:—

—Produce Markets' Review.]

FAIRY ROSES.

THESE have always been popular as room plants, and also among amateurs whose means for plant-growing may be described as limited, consisting only, perhaps, of a small greenhouse and frame or so. Latterly there have been some valuable additions made to the list of varieties. Not many years ago we could only obtain the old-fashioned crimson and pink varieties, known fully as well to our grandmothers as to ourselves. Now we have several beautiful pure white sorts, and a crimson far surpassing in brilliancy the old-fashioned one just alluded to. These newer varieties are not called Fairy Roses, but Polyantha Roses, an innovation which we do not approve of, on the ground that it is not so popular and homely. We would rather have the old name, if even there is nothing in it. These Fairy Roses ought to become very popular when they become better known. They are neat in habit, and have beautiful foliage and flowers, the latter produced in such profusion as only Fairy Roses can produce, above all they are so easily cultivated that they may be grown successfully by the merest tyro in the art of plant-growing. They are very easily propagated, to begin at the beginning, by means of cuttings. The tops of shoots three or four inches in length will make excellent cuttings. These should be placed in sandy soil in pots in the months of May or June, keeping them close in a cold frame, and shaded from the sun, but otherwise well exposed to light, till they are rooted. When they have formed roots let them be potted into $8\frac{1}{2}$ or 4 inch pots, and still be kept close till they have established themselves by making some roots. After this they should be more freely exposed to light and air, and be encouraged to make growth freely. As soon as the plants have filled their first pots with roots they should be shifted into larger pots; and the shoots should be stopped occasionally during the early part of the summer to induce business and compactness of habit. They should each have a stake placed close to the leading stem, which must be tied to it, so that the plant may be kept in good symmetry, somewhat pyramidal in form. Grown in this manner they will make nice, compact flowering plants, clothed at every tip with flower buds, which will last for many weeks during the spring and early summer following the period of propagation. Two-year-old plants may be treated during the growing period precisely as young plants after they are established in their first pots. The principal enemy they have is green fly, which, however, can easily be kept in check by means of a decoction of quassia and tobacco water, or soft soap, the latter being more cleanly as an ingredient in the wash than tobacco water. Mildew also is liable to make its appearance if the atmosphere is not kept well ventilated and healthy, but is easily dealt with by means of sulphur and soft soap in solution. Preventive measures are better than cures, and by frequently making use of the means indicated, neither pest will make its appearance at any time. The following are the best sorts:—Gloire, crimson; Pompon bijou, dark rose; Pamina alba, white.

AN ALARMING DISEASE AFFLICTING A
NUMEROUS CLASS.

THE disease commences with a slight derangement of the stomach, but, if neglected, it in time involves the whole frame, embracing the kidneys, liver, pancreas, and in fact the entire glandular system; and the afflicted drags out a miserable existence, until death gives relief from suffering. The disease is often mistaken for other complaints; but if the reader will ask himself the following questions, he will be able to determine whether he himself is one of the afflicted:—Have I distress, pain, or difficulty in breathing after eating? Is there a dull, heavy feeling, attended by drowsiness? Have the eyes a yellow tinge? Does a thick, thick mucous gather about the gums and teeth in the mornings accompanied by a disagreeable taste? Is the tongue coated? Are there pains in the sides and back? Is there a fullness about the right side as if the liver were enlarging? Is there costiveness? Is there vertigo or dizziness when rising suddenly from a horizontal position? Are the secretions from the kidneys scanty and highly coloured, with a deposit after standing? Does food ferment soon after eating, accompanied by flatulence or a belching of gas from the stomach? Is there frequent palpitation of the heart? These various symptoms may not be present at one time, but they torment the sufferer in turn as the dreadful disease progresses. If the case be one of long standing, there will be a dry, hacking cough, attended after a time by expectoration. In very advanced stages the skin assumes a dirty brownish appearance, and the hands and feet are covered by a cold sticky perspiration. As the liver and kidneys become more and more diseased, rheumatic pains appear, and the usual treatment proves entirely unavailing against this latter agonising disorder. The origin of this malady is indigestion or dyspepsia, and a small quantity of the proper medicine will remove the disease if taken in its incipency. It is most important that the disease should be promptly and properly treated in its first stages, when a little medicine will effect a cure, and even when it has obtained a strong hold, the correct remedy should be persevered in until every vestige of the disease is eradicated, until the appetite has returned, and the digestive organs are restored to a healthy condition. The surest and most effectual remedy for this distressing complaint is "Seigel's Curative Syrup," a vegetable preparation, sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White, Limited, 17, Farringdon-road, London, E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

Market-Place, Pocklington, York, Oct. 2, 1882.

Sir,—Being a sufferer for years with dyspepsia in all its worst forms, and after spending pounds in medicines, I was at last persuaded to try Mother Seigel's Curative Syrup, and am thankful to say have derived more benefit from it than any other medicine I ever took, and would advise any one suffering from the same complaint to give it a trial; the results they would soon find out for themselves. If you like to make any use of this testimonial you are quite at liberty to do so.—Yours respectfully,

(Signed) R. TURNER.

Seigel's Operating Pills are the best family physic that has ever been discovered. They cleanse the bowels from all irritating substances, and leave them in a healthy condition. They cure costiveness.

St. Mary-street, Peterborough, Nov. 29, 1881.

Sir,—It gives me great pleasure to inform you of the benefit I have received from Seigel's Syrup. I have been troubled for years with dyspepsia; but after a few doses of the Syrup, I found relief, and after taking two bottles of it I feel quite cured.

I am, Sir, yours truly,

Mr. A. J. WHITE.

WILLIAM BRENT.

"Hensingham, Whitehaven, Oct. 16, 1882.

"Mr. A. J. WHITE.—Dear Sir,—I was for some time afflicted with piles, and was advised to give Mother Seigel's Syrup a trial, which I did. I am now happy to state that it has restored me to complete health.—I remain, yours respectfully,

(Signed) JOHN H. LIGHTFOOT.

August 15th, 1883.

Dear Sir,—I write to tell you that Mr. Henry Hillier, of Yatesbury, Wilts, informs me that he suffered from a severe form of indigestion for upwards of four years, and took no end of doctor's medicine without the slightest benefit, and declares Mother Seigel's Syrup which he got from me has saved his life.—Yours truly,

(Signed) N. WEBB,

Chemist, Calne.

September 8th, 1883.

Dear Sir,—I find the sale of Seigel's Syrup steadily increasing. All who have tried it speak very highly of its medicinal virtues; one customer describes it as a "Godsend to dyspeptic people." I always recommend it with confidence.—Faithfully yours,

(Signed)

VINCENT A. WILLS,

Chemist-Dentist,

Merthyr Tydvil.

To Mr. A. J. WHITE.

Preston, Sept. 21st, 1883.

My Dear Sir,—Your Syrup and Pills are still very popular with my customers, many saying they are the best family medicines possible.

The other day a customer came for two bottles of Syrup and said "Mother Seigel" had saved the life of his wife, and he added, "one of these bottles I am sending fifteen miles away to a friend who is very ill. I have much faith in it."

The sale keeps up wonderfully; in fact, one would fancy almost that the people were beginning to breakfast, dine, and sup on Mother Seigel's Syrup, the demand is so constant and the satisfaction so great—I am, dear Sir, yours faithfully,

(Signed)

W. BOWKER.

CALCUTTA :—SATURDAY, FEBRUARY 7, 1885.

[No. 6.]

Crop and Weather Report.

[FOR THE WEEK ENDING THE 28TH JANUARY 1885.]

General Remarks.—There has been some rain in parts of Sindh, and in places in the Central Provinces, in the Central India States, and in Bengal. Rain has also fallen in most districts of the North-Western Provinces and Oudh, and in many places in the Punjab.

In Madras prospects continue to be unfavourable in parts of Bellary and Anantapore; elsewhere standing crops are generally in good condition. In Mysore the crops are in fair condition, except in the Kolar and Toomkoor districts, where prospects are not encouraging. The rice harvest has been completed in Coorg, and threshing has commenced. Coffee-picking still continues on European estates, but there is no demand in the local market for native produce.

Rabi prospects continue good in Bombay. In parts of Hyderabad and on the Upper Sindh Frontier, the standing crops have been injured by frosts. Scarcity of fodder continues in several talukas of Dharwar, Belgaum, and Kaladgi, and of drinking water in parts of Dharwar and Belgaum.

In the Derars, the Central India, and Rajpootana States, prospects are generally very favourable.

The *rabi* crops are flourishing in the Central Provinces and in the Punjab, and are generally in good condition in the North-Western Provinces and Oudh.

In Bengal, mustard, *mug*, and *kalai* are being gathered, and harvesting of paddy is finished, except on very low lands. The outturn generally has been below the average. Lands are being prepared for *boro* paddy and *aus* crops. More rain is required for the *rabi* crops.

In Assam the *sali dhan* has been nearly harvested, and lands are being prepared for the winter crops. The rice harvest has been gathered in the majority of districts in British Burmah, and threshing is in progress.

The mortality from cholera has again increased in Coimbatore and Tanjore. In other provinces the public health is generally good.

Prices generally are stationary, except in the Punjab where they are fluctuating.

Madras.—General prospects fair, except in parts of Bellary and Anantapore.

Bombay.—Rain in parts of Sindh; *rabi* prospects unchanged; standing crops slightly injured by frost in parts of Hyderabad and Upper Sindh Frontier, and by rats in one taluka of Nasik; scarcity of fodder continues in several talukas of Dharwar, Belgaum, and Kaladgi, and of drinking water in parts of Dharwar and Belgaum; cholera in parts of four districts; cattle-disease in parts of eight, and fever and smallpox in parts of twelve districts.

Bengal.—Rain fell in some districts; more rain is still wanted for later *rabi* crops; mustard, *mug*, and *kalai* are being gathered; harvesting of paddy, except that on very low lands, is finished, with an outturn generally below the average; lands are being prepared for *boro* paddy and *aus* crops; price of common rice is generally stationary; public health on the whole is good, though some cases of small-pox and cholera are still reported.

N. W. P. & Oudh.—Weather cold; light rain fell during the week in most districts; some injury to crops by hail and blight in a few places, but generally the prospects both of food and poppy crops are favourable; supplies are sufficient and prices easy; the health of the people and condition of cattle continue satisfactory.

Punjab.—Fever disappeared from Umballa district; health of rest of the province good; crop prospects generally good; prices rising in Lahore and Rawal Pindi, and falling in other districts.

Central Provinces.—Weather getting warm, cloudy at times; prospects continue favourable; health generally good; prices steady.

British Burmah.—Harvest gathered in majority of districts and threshing general; cholera prevalent in town of Prome and small-pox in towns of Thayetmayo, Henzada, and Mergui; elsewhere both diseases sporadic only; cattle-disease prevalent in one township of Bassein district, elsewhere very trifling.

Assam.—Weather seasonable; prospects of winter crops good; health good.

Mysore and Coorg.—Crops, health, and prospects generally favourable.

Benar and Hyderabad.—Weather clear and cool; cotton-picking continues; *rabi* prospects good; general health good.

Central India States.—Prospects good; weather clear and cold; health good.

Rajpootana.—Weather changeable, with occasional storm; health and prospects good.

Editorial Notes.

ACCORDING to a contemporary not only colonial wine-growers, but tropical planters who have been long struggling hopelessly with leaf disease in coffee, cankering cinchona, and other more or less mysterious enemies of vegetable life, will be interested to learn that a medical man in the department of Maine et Loire, France, is reported to have discovered a means of overcoming the phylloxera by an easy and inexpensive treatment, the basis of which is an arsenical solution mixed with cinders. The limited experiments made with this preparation seem to have been attended with admirable results. A vineyard selected from a neighbourhood completely devastated by the phylloxera, and subjected to the new treatment, resisted the scourge in a most striking manner. Not only the foliage and stocks, but the roots remained perfectly intact, while the fruit is said to have been abundant and of excellent quality. Further experiments on a large scale are about to be made in the Medoc; and the inventor having patented his remedy, the result obtained will receive all possible publicity. The outcome of these experiments, which are being conducted under the patronage of M. Lalande, President of the Bordeaux Chamber of Commerce, is awaited with the greatest impatience.

.

ANY one who has had occasion to travel by water in any Indian province, must have noticed huge pieces of timber lying along the banks of rivers partially immersed in water. This is the method generally practised in this country for seasoning wood. Now as our readers are aware that trees, immediately after they have been felled, contain a large quantity of moisture unless they have been previously killed, and are therefore unfit for use, until they undergo the process called seasoning. This means the evaporation of water which if permitted to remain in the body of the tree would ferment, and decay would be the result. On the other hand, if it be dried too rapidly, the gum and other matter in the wood would, in course of evaporation, disappear, instead of gradually assimilating with the fibres, and tending to bind them together, as in the case when the drying process is conducted with proper care. This renders the wood brittle, and therefore depreciated in strength. Now in regard to the method adopted in India, people are apt to think that immersing timber in running stream for a time, before stacking, helps to season it, and therefore is less liable to decay. In the first place this is not always possible; but even if it were, there are great drawbacks attending this process. It should be observed here that the timber being partially submerged under water, the action of the sun's rays acting on the portion exposed to the atmosphere causes cracks, and thus interferes with the soundness of the wood, while more matter is carried off than is necessary. To avoid this some people leave the timber in the bulk for a time before converting it into planks. This is also objectionable, for if there are any cracks through the bark to allow of moisture lodging in

it, decay is sure to set in. A correspondent of an American paper writing on the subject says, that the best way is to cut the timber into planks at once, after felling, and place it in a store room or shed with good ventilation, but no violent draught or air and no moisture. The floor should be perfectly dry and the roof lofty.

In stacking the timber, it is well, when convenient, to stand the planks on end, the root end upwards, and well raised from the ground. In all cases each plank or board should be separated from the next one by laths, to allow the air freely to circulate between them. After being in this position for four or five months, it is well to reverse them, and brush off with a hard brush any moisture or mildew that may appear. Timber seasoned in this manner proves the toughest and most durable. In seasoning, hard wood takes about one year to the inch, and soft wood much less. Where it is possible it is well to cut all timber into scantlings, and in panels or boards; to plane them some time before being used, as they are apt to shrink, no matter how long they are seasoning, for the wood which requires least seasoning is generally found to be the most durable; it then becomes an essential point that trees should be felled during the winter months, that being the season when the tree has least sap or vegetation within it. With regard to knots, it is easy to avoid them, as, generally speaking, the trunk shows in most cases the signs of the knots outside; but with shakes it is not so, for the trunk may appear perfectly sound and healthy, and even when cut into planks may appear sound, yet, when beginning to season, shakes may possibly show. The three principal kinds of shake are heart-shake, star-shake, and cup-shake; heart-shake is found in nearly all descriptions of timber, but in so small a quantity that it is of no consequence, while in others it causes the loss of nearly the entire tree. As a general rule it is not so wasteful as the star-shake and cup-shake, unless where it takes a twisting form. But in all cases it is only when timber is seasoned that the full extent of the injury is seen. In case of rot or decay it is not so much so, because it shows in the log, and with proper care in seasoning, decay can be prevented spreading.

THE expenditure on arboriculture in the Central Provinces during the year 1883-84 was Rs. 19,135, against Rs. 18,150 in the previous year. Of the former sum, Rs. 15,585 was provided from local funds, and Rs. 3,550 was expended by the Public Works Department in maintaining avenues and groves on the roads under their charge. Most trees were planted out in the Hoshungabad district. No planting operations were undertaken in the Nagpore, Chanda, Seoni, Mundla, Betul, and Raipore districts. Private individuals are reported to have planted out 9,434 trees in avenues, and 1,982 in groves, upwards of half of which were planted in the Hoshungabad district, and the next largest number in Nimar. In the returns from some of the districts, however, it appears that the number of trees planted from public funds and by private individuals have been mixed up together, so that it is impossible to arrive at the exact expenditure.

THE report on the Customs administration of the port of Bombay for the year 1883-84 has just been published. The nett revenue collected by the department during the year shows an increase of Rs. 1,87,964-5-10 over that of the previous year. In import duties, there was an increase of Rs. 59,446. To this sum Rs. 16,232 were contributed by increased importations of arms, ammunition, and military stores, and Rs. 49,046 by liquors. Calcutta having deprived Bombay of a large portion of the trade in Indian rice to African and Persian Gulf ports, there was a decrease amounting to Rs. 10,874 in the export duty. While the refunds during the previous year amounted only to Rs. 4,010, during the year under review they increased to Rs. 8,181. There was a large decrease of Rs. 1,42,800 in the amount of drawback paid during the year. The actual expenditure on account of establishments and charges connected with the Custom House proper amounted to Rs. 2,14,811, being less by Rs. 52,366 than the amount expended in the previous year. The financial results of the reductions of establishment effected in consequence of the abolition of a great number of import

duties, are shown for a complete year for the first time. The saving comes to Rs. 1,95,600, or very nearly two lakhs, the amount indicated in the Government of India Resolution on the subject. The bulk of the foreign trade was about the same as in the previous year, but the coasting trade was brisker. Mr. Pritchard remarks that the reduced establishment was able to cope successfully with the increased work devolving upon it.

ATTENTION is being given in the Punjab to the large quantity of box-wood which is to be found in various parts of the province. It is estimated that the total area known at present to be covered with box-wood is 1,300 acres. Only a part of this area contains pure box forest; in other parts the tree is found mixed up with other faster-growing trees, in consequence of which it becomes stunted. It is calculated that there are at present 7,777 mature trees, above two feet in girth; and the growing stock is estimated at about 17,500 trees. Prices vary from Rs. 102 at Jhelum, to Rs. 196 per ton, at Umrtsur and Simla; while in London, box-wood fetches £24 per ton. Including carriage to the port of shipment, it is estimated that the cost would be equivalent to £18 8s. 8d. per ton, which would give a much better profit than if the wood were sold in the local markets. It is not considered possible to secure at present an annually recurring out-turn, owing to the difficulties of working, but it is proposed to make four cuttings, one in 1884-85, another in 1891-92, another in 1899-1900, and a fourth in 1906-07. In the meantime experiments with regard to the reproduction of the tree have been instituted in all the forest divisions where it flourishes, and orders have been given for the strict protection of box-wood forests.

FROM statistics recently published, we find that the five principal coal-producing countries of the world are Great Britain, the United States, Germany, France, and Belgium. The mines of Spain and Russia yield a certain quantity of coal, and it is also worked to some extent in several of the dependencies of Great Britain, such as Nova Scotia and New South Wales, but practically speaking, the world's coal is drawn from the five countries named above. Now let us examine the course which production is taking in each of them. In Great Britain, 158,850,000 tons of coal, in round numbers, were raised in 1882, and 166,201,000 tons in the succeeding year. The production of the United States is also progressing, having risen in 1883 to 95,800,000 tons, as compared with 93,600,000 tons in 1882. Germany, again, produced 70,250,000 tons in 1883 as compared with 65,370,000 tons in the previous year. The production of coal in France in 1883 was 21,446,000 tons, while the corresponding production of 1882 was 20,603,000. In 1883 Belgium yielded 18,135,000 tons, and in 1882, 17,590,000 tons. Altogether the five countries produced between them 371,631,000 tons, of coal in 1883, as compared with 356,010,000 tons in 1882. It will thus be seen that Great Britain has fully maintained her pre-eminence in the matter of producing coal, and her extraction is growing more rapidly than in any of the other coal-yielding countries. Considering that nearly 45 per cent of the world's coal is raised in Great Britain alone, it is a truly marvellous result, when we come to examine the limited area of England, Scotland, and Wales. It is, moreover, an astonishing illustration also of what can be effected by labor and capital intelligently directed, even when the natural resources upon which they are brought to bear are less considerable than those existing in more extensive and more highly favoured regions. In the matter of the rapid increase of production, Germany ranks next. In France the progress is very slow, indeed, as will be seen from the following figures. In 1863 she raised 10,576,000 tons, while ten years later, that is, in 1873, the production was not carried beyond 17,886,000 tons, rising languidly in 1883 to 21,446,000 tons. The fact that while Great Britain has been increasing her coal production progressively at the rate of 7 or 8 million tons per annum, and in France, during the last twenty years, the corresponding average progress has only been 500,000 tons, we are irresistibly led to the conclusion that the French have failed to put sufficient energy and vigor into their coal-mining. We have shown above that the aggregate production of coal in 1883 in Great

Britain, the United States, Germany, France and Belgium, was 371,000,000 tons in round figures. In 1882, the corresponding production was 356,000,000 tons; in 1881, 332,200,000 tons; in 1880, 315,100,000 tons; and in 1879, 285,600,000 tons. We thus arrive at the astonishing fact that the production of coal in the five countries increased in the four years ending with 1883, inclusive, to the extent of 85,400,000 tons.

.

A CONTEMPORARY alluding to the subject says:—"We hear of the continued dullness of trade and the discouraging results of commercial enterprise, but in presence of the stupendous increase indicated in the production of coal by the figures which we have just cited, it cannot, we think, be fairly maintained that the coal-mining industry has been depressed during the past half decade. This remark holds good, at any rate, so far as the extraction is concerned, and the only question is whether the prices obtained have been fairly remunerative. Probably coal owners have suffered from the growth of competition, which has been a distinctive feature in all trades and pursuits during the last five or ten years. The main cause of the continual growth observable in the coal extraction of the five countries is, no doubt, the steady development of steam power and the increased domestic consumption resulting from the progress of population. The demand for household coal must have a tendency to grow as households are multiplied; but after all, the main explanation of the continual expansion of the world's coal trade must be found in the steady development of the world's steam power. Every day more and more steam engines are brought into operation, more and more railways are established, and more and more steamers are built. Hence it comes about that more and more coal must be raised to feed the steam boilers of the world."

.

We have been favoured with a printed copy of minutes of meetings held by the managing committee of the Bijour Agricultural Society, held during the latter part of 1884. A prominent feature of the managing committee deserves to be noticed here, viz., that with the exception of Mr. A. M. Markham, C.S., President, it is composed entirely of native gentlemen of distinguished abilities and position. We earnestly hope the example will be more widely followed in other parts of the country. The Secretary, Pundit Sri Lal, reports the death from cattle-disease of the Cawnpore bull, which was the property of the Agricultural Department, but was provided to the Society on an annual hire of Rs. 16. He also submitted the Director of Agriculture and Commerce's letter addressed to the Collector of Bijour on the subject of purchase of bulls from the Hissar Farm. The purchase of these bulls being very high, it was resolved to get as a substitute one from Kanwarya. An additional contribution of Rs. 150 was made to the Moule Garden Fund. The income during the year was estimated at Rs. 2,891, and the expenditure at Rs. 2,812, leaving a balance of Rs. 79 only. A letter from the Director of Agriculture and Commerce to the address of the Collector of Bijour on the subject of the Secretary Pundit Sri Lal's proposed visit to England, was considered, and it was resolved that the Collector be informed that the Society accepts with gratitude the offer of Government and its own responsibility for one-half of any further expenditure, which may be found necessary in connection with the Pundit's visit to England. As, however, of his private subscription of Rs. 600, Rs. 300 was at once required by him to pay for his passage home, the committee trust that a deposit of Rs. 3,000 will be considered sufficient by the Government, and this sum they were prepared to deposit at once in the treasury. The entire cost of the trip, including board and lodging at Cirencester, during the seven terms, and elsewhere during college vacation, with all incidental charges, was estimated in round numbers at Rs. 8,600. Of this sum half were to be provided by the Society, and the other half by the Government. To the honor of a local celebrity, Raja Juggut Sunker Bahadoor, be it said, that he subscribed the sum of Rs. 2,000 towards this laudable object. The following seeds were distributed among the members of the Society for experiments during the *khari* season:—New Orleans cotton, Nankin cotton, sorgho amber, black sorghum,

Jaunpore maize, American maize, Guinea grass. We are glad to learn that the Society's *Agricultural Journal*, published since March last, has met with a favourable reception at the hands of landholders and others interested in agricultural improvements. There are now 800 names on the list of subscribers against 600 in March 1883, when the first number was issued.

.

THE *Journal of the Society of Arts* draws attention to a report by Mr. Consul Griffin, of Auckland, on the Tamkatra bark (*Phyllocladus trichomanoides*), which he says has been exported to Europe of late years in very large quantities, in consequence of its being so highly prized for dyeing and tanning, "recent tests having established the fact that it is one of the best vegetable dyes in the world, and especially for yellow, pink, and fawn colours." An interesting fact connected with the tree is said to be that it produces a most beautiful walking-stick. The bushmen bruise the bark of the sapling at regular intervals, and after a few days, cut the sapling down and peel off the bark. The stick then presents a mottled surface, and of a permanent bright red and white colour. In obtaining the bark for exportation a transverse incision is made with a knife round the trunk at the bottom, and a similar cut just below the junction of the branches; vertical incisions are then made with a very sharp knife, and the bark removed in long narrow strips, and all the branches large enough to contain bark of any value are stripped in the same manner. The tree, if not too large, is generally cut down, and the bark is thus removed more easily, it being useless to endeavour to save the tree, as removing the bark invariably kills it. The barking usually takes place in the winter, though it is said that it would be preferable to collect it in the spring, at which season the tannin is most abundant. The bark, when peeled, is put up in bundles from 4 to 5 feet in length, and is then ready for shipment, usually to London, whence it finds its way to Grenoble, where it is largely used for dyeing kid gloves. It is only of late years that Tamkatra bark has been exported from New Zealand, and owing to its valuable properties, it is expected that the trade in this article will largely increase. In 1873 the amount exported was 24 tons, while during the first six months of 1883—the latest date for which returns are available—it exceeded 575 tons, with a value of £4,000.

.

THE wine productions of France for the year 1884 is given in the official statistics just issued at 34,780,726 hectolitres. This is more than a million less than that of 1883, but four millions more than that of 1882, and about three and a-half millions more than the average of the last five years. The result may therefore be pronounced satisfactory, the more so as the quality of the wine is above the average. The wine-planted area is, however, constantly lessening, in consequence of the ravages of the phylloxera. In 1874 there were 2,446,000 hectares of vineyards, but at the present time these do not cover more than 2,040,759 hectares. Last year alone the reduction, notwithstanding fresh plantings, was 55,000 hectares. To meet the deficiencies of the home production, there has been an increased manufacture of artificial wines, and also increased importations. As much as 2,885,000 hectolitres were last year produced by the addition of sugared water and by the fermentation of raisins. Up to the end of November the importations amounted to 7,219,000 hectolitres. One satisfactory feature is afforded by the increased cultivation in Algeria, from which 896,291 hectolitres were last year obtained.

.

THE second report on the prospects of the cotton crop in the Bombay Presidency is as follows:—Complete cotton reports not received. Kaladgi crop has withered, estimated outturn 1 to 3 annas. Dharwar, crop middling, exotic cotton in places blighted, outturn 8 annas. Belgaum, crop middling, outturn 7 annas. Ahmednugger, crop has in most places withered, outturn 2 to 6 annas. Sholapore, crop entirely failed. In Nasik, crop much injured by heavy rain in December, outturn 4 to 10 annas. Satara, outturn 14 annas. In Surat, December rain has slightly injured the crop, outturn 12 annas. Broach, crop in places damaged by blight and cloudy weather, outturn 9 annas. Ahmedabad, crop middling, outturn 9 annas. In Sindh condition

In places good, in others bad and fair. Kathiawar, crop tolerably good. Kolhapore, crop middling. The prospects of the cotton crop in the Bombay Presidency are unsatisfactory. In Kaladgi the crop has almost failed, and the yield of the other important cotton-growing districts is estimated at about 9 annas.

At the last Smithfield Club Show, was exhibited the first large display of ensilage yet seen in Europe. Mr. H. Kains-Jackson, referring to this exhibition, says:—"The entries, 330 in number, are the largest percentage of exhibitors—in proportion to the total number of silo proprietors—that has ever been made at any English or foreign agricultural show. They represent ensilage from diverse substances, made from all parts of the kingdom. For making the awards, five judges have made a close examination of the specimens. These specimens were received in sample boxes two feet in length, so that when sawn asunder a clear sample of a cubic foot might be untouched, whilst the dual specimen could be pulled to pieces and otherwise be examined. The champion award was made by Mr. Henry Woods, agent to Lord Walsingham, of large experience and practice in making ensilage, and myself, from the six prize samples selected by the judges." The prize samples are exhibited on the stand of Messrs. James Carter and Co., seed farmers and merchants, No. 66, in the North Gallery. The following is a list of those exhibitors who have obtained first prizes in the various classes:—Champion Prize—A silver cup, or purse of ten sovereigns. No. 125 in class 2, Mr. John Swan, Lincoln; 215, Mr. William Oliver Howpasley, Howick; 25, Mr. A. M. Cardwell, Valley House, Horsted, Keynes; 224, the executors of the late Mr. F. Eagle, Hall Farm, Brightlingsea, Essex; 122, Mr. A. H. Grant, Abbotswood Manor, Romsey, Hants; 45, Mr. Thomas Powell, East Lenham, Maidstone; 125, Mr. John Swan, Stonefield, Lincoln; 201, Viscount Gage, Fittle, Lewes; 219, Mr. W. E. Oakley, the Home Farm, Tan-y-Bwlch, Merionethshire; 299, Mr. Edwin Brett, White Knobs Farm, Caterham Valley; 294, the representatives of the late Marquis of Londonderry.

THE report of the Directors of the Devala-Moyar Company shows that the mining works are not altogether without hope. From 225 tons of quartz, 25 ozs. 12 grains of gold have been obtained, which is equivalent to 2 dwts. 5 grains. Such a return would of course never pay expenses. Its chief importance lies in the fact that the reef continues to be auriferous. At times the prospect is reported to have given as much as one ounce to the ton. Mr. Gitchell still thinks that something better may be found under the mountain. The agricultural prospects are good. The report of the Directors of the Indian Consolidated Company states that since June complete statistics have been furnished of five milling results. The richest quartz treated contained by average of assay 3 dwts. 20 grains to the ton, and the milling results have been 74 to 76 per cent of the assay values. The Directors add:—"If quartz were obtainable sufficient to keep the 20-head mill at work, which would yield from four to five pennyweights of gold per ton, its value would probably defray the expenses of the undertaking. The reef, as far as it has been explored, is generally wide, well defined, and persistent in its course, and may yet be found to enclose remunerative shoots of quartz." A good deal of attention has been paid to planting, but the cash produce from this is a matter somewhat in the future. The Directors are trying to acquire a property in the Mysore district, about which they speak somewhat darkly in their report.

THE following account of the opening of a silo given by a contemporary will be read with interest:—"On Monday morning a goodly number of the residents of Lucknow assembled to witness the opening of a silo pit in the compound of the Civil Church. The pit was filled with wet grass in the beginning of August. The first sight of the preserved grass was not encouraging. It looked like a mass of mouldy matted vegetation, and emitted a pungent alcoholic smell. However, after a few inches had been removed, there was a perceptible improvement in the quality of the grass, and it quite fulfils the expectations of the chaplain. A pair of bullocks, apparently not

abstainers, ate it with relish, notwithstanding its alcoholic properties. The greater part is quite sound, of a darkish yellow colour. At the bottom of the pit, next to the floor of broken bricks, the grass was welded together in a mouldy mass, and came away like torn matting. The sound part is now being dried, and it is expected that it will turn out to be good fodder when dry. The loss from mould was due to the faulty construction of the pit which, having no masonry sides, had to be dug on the slant—thus preventing an uniform downward pressure, and allowing of the entrance of moisture sideways from the surrounding soil."

ACCORDING to an English paper, a grand duello is now going on between two of the more recent sources of food supply at home. It says that until quite recently the Australian tinned meat trade distanced all competitors in its particular province. Efforts were made, from time to time, to win British favour for frozen meat importations, but with very little success. All this time, the importations of tinned meats continued to increase with startling rapidity. Beginning with the modest quantity of 4,702 cwts. in 1866, the trade reached its zenith, according to McCall's annual circular, in 1880 when 665,800 cwts. were landed in England. In the following year, however, there was a sensible falling off, and although 1883 witnessed a slight recovery, last year's record brings down the figure to 446,000 cwts. This large decrease is partly attributable, it appears, to the higher cost of the article consequent upon the exceptional demand in 1880. But English consumers would probably have been content to pay a little more for food to which they had grown accustomed, were it not for the superior attractions of frozen meat. That which has recently been coming from New Zealand in enormous quantities—one steamer lately landed 25,000 sheep's carcasses—is a vast improvement on former importations, and now that it can be bought under its proper name at a low price, instead of as English mutton at a high one, it is coming into great favour among people of limited income. There is, however, a dark side to this picture. The latest news from the Colonies is not very hopeful. Owing to the continued drought for months, large tracts of country have been completely denuded of sheep and cattle. The loss in the former is estimated at about five millions. The frozen meat trade in the continent of Australia which gave such promise has been almost crippled. A large firm in Victoria has been worked at a loss of £5,000. The price of butchers' meat four years ago was 2d. to 3d., beef 3d. to 4d. per pound. Now mutton has risen from 6d. to 7d. per pound, and beef from 9d. to 10d. Butter is selling at 1s. 3d., and cheese at a shilling. In the matter of wheat, cultivation, the prospects are anything but cheering—at present it hardly covers the cost of production—and the rapid development of the wheat trade of India will only tend to make matters worse.

THE second report on the prospects of the wheat crop in the Bombay Presidency is as follows:—"Complete wheat returns have not been received. Dharwar 399,809 acres, seedlings germinated, crops middling. Ahmedabad 274,043 acres, crop withering in parts; crop damaged by cloudy weather. Nasik 260,860 acres; crop on the whole good, in gardens, crop likely to be blighted owing to December rain. Ahmednugger 249,518 acres, crop in places good, in others middling and poor owing to cloudy weather and excessive rain. Kaladgi 161,571 acres, crop in most places withered, no out-turn expected. Broach 119,238 acres; crop very promising. Belgaum 107,911 acres; crop on the whole fair; in some parts it is injured by heavy rain and hailstorms, in others withering. Poona 99,245 acres; crop generally doing well; in parts it is affected by rust. Sholapore 46,253 acres; crop fair. Surat 38,570 acres, crop good. Kaira 36,341 acres, crop good. Kolhapore 37,108 acres, crop middling. In Sindhi crop progressing well, and in places shows prospects of a good season. Generally speaking, the wheat crop is good in the Guzerat districts, in the Deccan and Carnatic districts, except Kaladgi. The prospects of the crop have improved since the last report owing to the November and December rains.

In regard to the Mysore Gold Mining Company, Captain B. D. Plummer reported on the 2nd ultimo to his Directors:—"In Taylor's shaft, under the 173, the lode is looking as kindly as ever, but it is dipping north-west faster than the shaft can follow; assay value 4 ozs. 18 dwts. of gold per ton. In the south end the lode is not so kindly looking as it was, but we are now getting south of the ground the old men worked upon. The lode is 3 ft. 6 in. wide in the north end, but all the rock below the 173 is very hard and spare to cut. The No. 1 winze, under the 173, is down within 2 ft. of the back of the 60 ft. level, and as the water is so quick, I have stopped it until the end is driven to it. Strange to say no lode of any value has been met with in this winze; I am disappointed in consequence. In No. 2 winze under the 173 there is a very small rib of quartz, but of no intrinsic value. The progress has been very slow in the 173 north end on west lode. I have got another company of coolies to work it, and, perhaps, better progress will be made. The rock in the 173 north end on east lode is promising in appearance, and there is a rib of quartz 3 in. wide. In the 173 cross-cut west from east lode very good progress is made. The lode in the 173 rise in back of level is 3 ft. wide; no assay has yet been made. The 135 north end on east lode is uncommonly good looking quartz, but there has not been any assay yet made. Stamping: This goes on in a satisfactory manner. We have the four sets of elephant stamps at work, but the bulk of the ore we have to stamp is of low grade; however, we shall be able to send you home for this month a pretty good gold bar, though not so much as last month."

**

Mr. J. S. GAMBLE, Conservator of Forests, Northern Circle, reported to the Board of Revenue as follows:—"The question of what is the best tree to plant for avenues is entirely one of (1) climate and (2) soil. The same trees which would form magnificent avenues along the roads in Malabar would, most of them, fail altogether along those of Bellary or Vizagapatam. So far as the Northern Circle is concerned, omitting Nilgiris, the climate is dry, with the few exceptions of the hill tracts of the Circars of the Nallamalai hills. Scarcely anywhere does the rainfall exceed 50 inches. On the other hand, the soil varies extremely from the alluvial plains of the Godavari delta to the nearly bare metamorphic plateaux of Cuddapah and Bellary. Roughly speaking, however, we may classify the soils as follows:—(1) Rice lands on alluvium. (2) Laterite and the red soil which is produced by its decomposition. (3) Decomposed metamorphic soils, and gravel or sand and boulders. (4) Black cotton soil. (5) River sand. Along roads passing through the great rice country like the coast from the Godavari delta down to Pulicat, probably no better trees can be found than the figs, viz., the Banyan (*Ficus bengalensis*), the Pipal (*Ficus religiosa*), and the Pakar (*Ficus infectoria*), with its allies (*Ficus benjamina* and *Ficus tsiels*). On these, the first is the best, though to avoid the damage referred to in the Board's paragraph 2 it might be kept away from bridges or culverts. There is probably no tree which so quickly reaches a size fit to give shade as the banyan, and it is easily propagated by cuttings consisting of stout poles, perhaps even 6 to 12 inches in girth and 10 to 12 feet high. They must, of course, be planted during the rainy season and fenced, and if the rains fail afterwards, they may require watering. In such places also the mango does well on ground slightly raised above the level of rice fields, and the Margosa (*Melia azadirachta*) and Jaman (*Eugenia Jambolana*) will also thrive. Another good tree for such places is the Kadem (*Anthocephalus Cadamba*) which is very fast grown and easily raised. Near the foot of the hills, *Pterocarpus marsupium* might perhaps be grown with advantage. On laterite and lateritic soils the mango generally thrives well, and the jaman will also grow; but the figs should be avoided. Teak may be grown, but is a very bad avenue tree, as it is leafless when shade is most wanted, and the shedding of its large leaves is probably bad for the roads. But whatever is planted, care must be taken to dig the hole deeply, and provide good soil to fill them when the planting takes place."

**

On high level sandy soils, the result of decomposed gneiss and schists, figs may be grown if the soil is fairly good and the holes are well dug. So may the mango, but the best

trees are the tamarind, the margosa, and the sankesula (Telugu) (*Poinciana elata*). Good avenues of these may be seen in various parts of the Cuddapah plateau, in Karnool, Bellary and Anantapora. Another very good tree is the Kanuga (*Pongamia glabra*), which gives a good shade and has a fruit which is valuable for its oil. The Dirisana (*Albizia lebbek*) is much grown in such places, but is untidy and by no means so useful as the margosa, which has the valuable property of being in full flower and young leaf in the hot season when its shade is most necessary. On black cotton soil there are only a few trees which thrive. The tamarind and margosa are perhaps the best, but a good plan is to grow the Babul (*Acacia arabica*) rather thickly by sowing in large patches protected by thorns and then thinning out to one or two good stems. Other, but smaller, trees which will grow are the *Parkinsonia aculeata*, *Albizia lebbek* and *Balanites aguyptiaca*. When river sand has to be planted—which occasionally happens—probably the best tree is the palmyra palm (*Borassus flabelliformis*), but the jaman, margosa and babul may also be grown, while near the sea there are few kinds so useful as *Calophyllum inophyllum* and *Terminalia catappa*. In some places the casuarina may be grown, but it is often untidy and does not give a good shade in avenues. There are many other trees which are occasionally planted in this presidency. There is the *Cassia siamia*, to which his Excellency the Governor referred as being so common round Madanapalle, though, as remarked by him, it rarely makes a good avenue tree. There is the Deodora or Asoka (*Polyalthia longifolia*), which makes a beautiful avenue tree when it thrives, as it does in places along the coast. The Cork-tree (*Millintonia hortensis*) is often planted and is very pretty and sweet-scented but brittle, and so is the gold-mohur tree, the brilliant *Poinciana regia*. Near canals where the soil is not salt, *Sissu* (*Dalbergia sissoo*) is useful, and as along the Kendrapara canal, in Orissa, the coconut and *calophyllum* may usefully be grown where there is some salt in the soil. To sum up, for general purposes, the best trees are the banyan, mango and margosa, but where special circumstances make others necessary, some of those I have mentioned will probably be best to use. On the subject of avenue planting, I would recommend the consultation: Ribbentrop's 'Arboriculture in the Punjab' and Sinclair's 'Notes on Arboriculture in the Bombay Presidency,' a little book lately published by the Bombay Agricultural Department. Before concluding, I would beg to offer a few remarks regarding roads on the Nilgiri plateau, where the presence of avenue trees or an avenue belt is so valuable as a protection against the cold bleak winds of either monsoon. The value of the belt of Blue gum (*Eucalyptus globulus*) and Wattle (*Acacia melanoxylon* and *Dealbata*) along the road from Coonoor to Ootacamund is obvious to all who travel along it in bad weather, and this belt should be continued along all public roads. The best tree to use is undoubtedly the *Acacia melanoxylon*, which is stronger and more shady than the others, and not troublesome like the silver wattle; but some conifers, and specially (*Cupressus macrocarpa*) should also be grown. Where such roads cross swampy land, Willow (*Salix tetrasperma*) which grows most readily from cuttings, should be planted."

**

THE accounts of the Cinchona and Devala Moyer Company show a profit on the year's working of £591. The cultivation expenses of coffee and cinchona amount to £2,735. The proceeds of the coffee crop were £1,766, of cinchona £1,112. Dividends on investments and interest were £2,476. The report states that the time had not yet come when they could arrive at a decision as to the real value of the Company's mining property. THE Directors cannot advise as yet abandoning the mining enterprise, involving, as it would, the total loss of the capital expended; and they propose continuing to push on the works with vigour. The cinchona trees were being increased in number; the nurseries also were in a flourishing condition. The possibility of profitably cultivating rhea and other grasses is continuing to have the Directors' attention; but the time has not yet arrived, in their opinion, for taking positive action. The proposed agreement with the Rhodes Reef Gold Mining Company has been made, and the liquidation of that Company is proceeding in the manner contemplated.

THE following extract taken from a special report submitted lately by the Commissioner of Coorg on the subject of coffee enterprise, will be found interesting :—"The cultivation of coffee was introduced into Coorg, in 1835 by Major LeHardy, the first Superintendent, was confined at first to the two estates on the Mercara plateau, known as 'Beuvoir' and the 'Mercara estate' and to a few holdings owned by Mopla settlers near Nalknad in the Padinalknad Taluk. In 1858 land was opened on the Periyambadi Ghat, and in 1863 a great stimulus was given to the enterprise by the rise in the price of coffee, when clearings were first made at Madenad on the Sampaji Ghat. Unfortunately some of the first settlers who came from Ceylon set the pernicious example, which was followed by all planters for the first fifteen years, of clearing and burning the forest instead of adopting the safer but less remunerative method which is followed in Mysore of growing coffee under primeval or secondary shade. Other mistakes were made in land having been taken up for cultivation without regard to the excessive rain-fall and the steepness of the hill-sides. The forest, which crowned the mountain crests and covered the rocky spurs, was indiscriminately felled, so as to obtain a large open field for coffee, by which means the estates were deprived of valuable leaf manure, and the greater portion of them became exposed to the full blast of the south-west monsoon, or the still more trying hot east winds. So long as labor was cheap and plentiful, the system of hand weeding, which caused little disturbance of soil, was followed; but as it grew dearer, the *manoti* (native hoe) came generally into use for the removal of weeds, which grew rank and long from not being eradicated in time. It would not have mattered much, had the lands been comparatively flat as in the 'Bamboo' and in the Wynad where it is practised with advantage, but in a mountainous country with a heavy rain-fall varying from 140 to 240 inches in the year, it loosened the surface soil so greatly as to lead to its being gradually washed away; and the trees thus became unable to assimilate nutriment, even when supplied to them in the form of expensive manures. The system pursued was not only faulty, but climatic influences and pests, over which the planters had no control, have greatly tended towards the deterioration of estates. The seasons have proved of late years most unfavorable, especially on the Sampaji Ghat, where the early blossom showers, which are expected in the end of March and in April, did not fall till May, which was too late to ensure the healthy development of the blossom and fructification of the berry during the monsoon. The coffee trees have suffered also from borer (*xylocorychus quadrupes*), bug (*lecanium coffee*), and leaf rot, and lastly from the leaf disease (*hamedia castatrix*) which has caused so much loss in Ceylon."

.

It may be safely asserted that the pioneers, who obtained free on application large tracts of forests from Government and had the advantage of cheap labor, and the valuable compost arising from the burnt forest to aid the cultivation, were the only persons who derived substantial profits; but it was only for the first few years, and chiefly from the high prices paid to them for the land by the companies which they succeeded in establishing. As profits decreased through mismanagement and the ravages caused by the borer, less funds were available for high cultivation, which became essentially needed, owing to the rapid deterioration of the soil. The result has been that all the companies were wound up within a few years, and many of the estates fell at almost nominal prices into the hands of the managers and agents, who, though experienced men, became thus possessed of much more land than they could well cultivate. Subsequently with adverse seasons the condition of the estates has been passing from bad to worse. The humus having been washed away, it seems only a question of time as to when their entire abandonment will take place. On many estates only long rows of weather-beaten sticks are to be seen, bearing a few shrivelled leaves with a few patches of good coffee still left in low-lying valleys and in sheltered nooks. Such being the case, it is no ground for surprise that these properties have now no market value; for when put up to auction, no bids are made for them. There are a few estates, which are not quite so bad as others, owing to good management and high cultivation; but it is doubtful

whether any of the forest or ghat estates have of late years been worked at a profit sufficient to meet the interest on advances made by firms, any realized in one year, such as the last, being fully absorbed by the losses which have accrued in the years preceding or following. These statements are supported by the testimony of unanswerable facts. Between the year 1870 and 1880, 18,476 acres of coffee land were abandoned, and are now over-grown with *lanthana*; in 1881, 593 acres; in 1882, 2,156 acres; in the current year resignations have been received for 2,314 acres, making a grand total of 23,569 acres, which at Rs. 2 per acre (the assessment charged) represents an annual loss in revenue to Government of Rs. 47,138. The loss of capital to those who have invested in the enterprise cannot be so accurately stated, but it may be roughly estimated at £67,000."

.

"ALTHOUGH planters have become wiser after their dearly bought experience, it cannot be denied that errors were made by the authorities in the commencement by the free grant to them of too extensive tracts of forest land without any stipulations as to the reservations of belts of forest and the mode of culture. Government did not, however, remain wholly callous to the losses which were taking place; for, consideration was shown in the remission of the assessment due on portions of estates which had to be abandoned; while others received in exchange valuable land in the 'Bamboo,' by which they were enabled to recoup the losses which they had sustained on ghat land. The latter arrangement was, however, so obviously detrimental to the interests of Government and unfair to new-comers, that it had to be discontinued. Lately, the continued losses which the planters generally have suffered, and the sight of the deserted bungalows and *lanthana* covered estates, which meet the eye all along the Sampaji Ghat, and in the greater part of the forest and the Mercara plateau, have necessitated the grant of still more liberal concessions in the way of remissions and suspensions of assessment, in the hope that proprietors and mortgagees, notwithstanding the difficulties which surround them, may be encouraged to undertake the cultivation of other products, such as *cinchona*, *cardamoms*, *tea*, and *rubber* on lands which are unfit for coffee, and the abandonment of which has been frequently contemplated."

THE DEPARTMENT OF AGRICULTURE IN MADRAS.

THE Report of the Director of Agriculture and Revenue Settlement for 1883-84 has recently been issued by the Government of Madras. It is dated 16th September, but as it was submitted through the Board of Revenue, there has been some delay in its appearance. Up to the year under review, 11 districts of the Presidency have been revised and settled. The Settlement Department has been at work for 26 years, and in that time has dealt with an area of 12,933,493 acres. The immediate financial result of the re-settlement of districts was an increase of Rs. 16,39,553 to the former assessments. This increase represents a return of 7.3 per cent, on an outlay of Rs. 2,22,38,700, of which Rs. 75,29,507 represent the expenditure on settlement, and Rs. 1,47,09,193, that on survey. In regard to the organization and maintenance of village records, upon which so much stress was laid in the G. O. of the previous year, all that seems to have been done is to record a discussion that took place about rendering the post of Revenue Inspectors, or *Kanungos*, a qualifying grade for Tehsildarship; we cannot congratulate the officers, on their success in giving "a record of standing information regarding the agricultural conditions of each district." The second head deals with the analysis of districts with reference to security from famine. This system has been inaugurated in conformity with the requirements of the Government of India, as set forth in paras. 9 and 10 of their Resolution of the 8th December 1881. Kurnool being one of the smallest districts in the Presidency, and as it suffered more severely than any others that were stricken with famine, between 1876 and 1878, it was taken in hand first. We will quote here the words of the Report to show how far matters have advanced in this direction. It says :—"So far as materials are available here, the analysis is nearly completed, but the enquiry has revealed how much is wanted to make the

analysis as complete as the Government of India wish it to be. So far as the district generally, or certain well-defined sections of it, are concerned, the information that is available in this and the Board's offices would suffice for broad and tolerably accurate conclusions regarding its agricultural conditions, but the Government of India prescribe an analysis that is much too minute to be satisfied without considerable local enquiry. The information at head-quarters does not generally go below taluks, whereas the requirements of the Government of India demand an examination of the condition of villages." Considering that the instructions, based on the recommendations of the Famine Commission, were given so far back as 1881, we may safely presume that if a little more despatch is not used in travelling beyond the initiatory stage, it is likely another calamity may overtake the country before we can utilise the results of past experience for any practical purpose. The report makes a clean breast of its shortcomings, and acknowledges that any rapidity of progress is impossible without other help than the ordinary establishment of the office can afford. It is therefore proposed to ask the assistance of the Agricultural Reporter and the staff of agricultural inspectors for the work. The question now is, whether any additional burden can be thrown on the shoulders of these already hard-worked gentlemen without detriment to their legitimate duties. In connection with forest protection, it appears from the administrative report that the area of reserved forests in the Presidency, at the end of the year under review, was 2,869 square miles, of which 132½ square miles were reserved. The chief operations of the year were the planting up of three acres of the farm land with *Divi-Divi* (*Cosalpinia coriaria*) and the importation from Queensland of a large quantity of eucalyptus seed for distribution to districts. The Australian Salt Bush (*Atriplex nummularia*) seems to have done fairly well at the farm, where some of the plants have seeded. Attention also has been given to the discovery of indigenous salt-feeders, which might be found effective in the reclamation of saline soils and as useful for fodder as the bush of Australia. One variety found at Ennore is eaten freely by the cattle, and is identified by Professor Lawson as the *obione konigu*. Under the head of irrigation we are told that no new work was undertaken; the minor irrigation works, that is, all works irrigating less than 200 acres, are now managed in the Revenue Department. These works irrigated a nominal area of more than 112,000 acres, and the revenue derived was close upon Rs. 6,00,000; a little more than half of this amount was expended in repairs. Lands irrigated from wells sunk in dry land have in the Madras Presidency been long exempted from extra assessment on this account, but lands, whether wet or dry, irrigated from wells sunk in irrigated lands, have not hitherto shared in the exemption. On this subject, a communication was addressed to Government by the late head Sheristadar to the Board of Revenue, in which he urged that the principle should be extended, at least partly, to lands irrigated from what are known as "ayacut" wells. The Director of Agriculture agreed with the proposal submitted to Government, provided the wells were the sole source of supply. The Board of Revenue, however, did not endorse these views, as the subject was very fully discussed some years ago, and they did not see the advisability of re-opening it. But the Government took the former of the views of the matter, and has granted the concession. The Government Farm and the School of Agriculture at Saidapet has hitherto been managed by Mr. Robertson, who was at once Superintendent of the Farm and Principal of the School. But from the 1st of April 1884, this arrangement has ceased; and while Mr. Robertson has been placed in charge of the Agricultural College, Mr. Benson has become Agricultural Reporter and Superintendent of Farms. Mr. Benson reports on the agricultural conditions of the year as being very unfavourable; they are characterised as long droughts followed by heavy rain-fall; "the consequence was the universal loss of the grain crops from insects, rust, mildew and other diseases." The only crops that did fairly well were *ragi*, and some of the irrigated paddy. A great many experiments were undertaken at the farm with indifferent results; excepting the trial of red and white wheat from the Punjab. The experiments with manures, the most noticeable of which was with common salt, used as a top-dressing for *ragi*, and *sorghum saccharatum*, gave indifferent results. This is no doubt due to the pooriness of the soil, for at para. 87, Mr. Benson "doubts whether any really useful manuring experiments can ever be carried out on the Saidapet farm," and in another communication he is more explicit by expressing the opinion that to experiment there with manures is "a waste of time and money." He is not singular in his belief, for as pointed out by Mr. Robertson, the land is only fit for growing fodder. The Board of Revenue remarks on what Mr. Wilson says regarding the farm:—"The Board have on several occasions lately placed before Government their views on the failure of this farm, and need not now reiterate them. They, however, emphasize the tone of regret for wasted opportunities which underlies these eleven paragraphs of the Director's Report." We fail to endorse the Board's views on the subject, for after going carefully through them, we fail to see any indication of a single opportunity having been allowed to waste. We can

pretty well guess at the meaning of the Board; it was a covert attack upon the so-called neglect of Mr. Robertson, who has evidently been singled out as the scapegoat, upon whose devoted head the vials of the Board's wrath has been emptied. Of experiments with seed and plants, very little need be said as they were almost universally failures; but one very useful and interesting fact was elicited as the result of a trial made by Messrs. Minchin & Co., of Aska, with *Sorghum Saccharatum*, viz., that though it may be impossible to make a marketable sugar from the syrup of the plant, its fresh juice may be fermented and used by the distiller for the manufacture of spirits. In the sale and distribution of agricultural implements, Messrs. Massey & Co. of Madras carried off the palm. The popularity of their ploughs may be judged from the fact that of a single type known, as "the improved country plough," they have sold no less than 587,206. Next comes the firm of Messrs. Thompson and Mylne, of Beheea, in Behar. During the current year they sold eighty-one of their portable sugar-mills, from January to August, of which seventy-five went to the single taluk of Hospet in Bellary. Several experiments were made with fibres. China and Cashmere silk-worms were found to thrive very well during the cold weather when there was sufficient food for them. The limited supply of the mulberry leaves, however, interfered with the success of the experiments. At Saidapet the worms refused to touch any but mulberry leaves, which accounts for the great mortality among them. In Rajamundry the defective supply of those leaves was supplemented by lettuce leaves. Mr. A. J. Stuart reported a most interesting experiment which he had made with the indigenous *tussur* silk-worms found in his district of North Arcot. The cocoons that were found in the jungle were placed in a cage made of bamboo, and hung among the branches of a country almond tree, to which the worms, when hatched, had free access, the leaves affording them sustenance. The cost of the experiment was a mere trifle, and it was found that the worms required little care. Of all the experiments tried for the solution, by a chemical agent, of the cement which glues the fibres of the tussur cocoons so tenaciously together, the most successful was a solution of one-fifth pound of carbonate of potash in a gallon of water. The other agents employed, although successful, were found to injure the thread.

Miscellaneous Items.

DURING the month of December, 46,413 bales of cotton, valued at Rs. 39,97,003, were shipped from Bombay.

THE ship *Rajah of Oochin* has been chartered to convey about 300 emigrants from Madras to the Mauritius.

THE Murree Brewery Company have obtained permission to erect an iron structure within the Arsenal-square, in the Fort of Bangalore, so as to utilise the existing building for brewing purposes.

THE King of Corea lately issued an edict, in which he strongly remonstrated with the misdirected policy of the young men of the country, in aiming at official appointments to the neglect of their own trades.

MORE gold-fields are reported to have been discovered on the Russo-Chinese frontier of the Amoor, twelve miles from the frontier, on the Chinese side. The Russians are going over to the fields in swarms.

IN exercise of the powers conferred by the Court Fees Act, 1870, the Governor-General in Council has remitted the fees payable on applications for loans under the Agriculturists' Loans Act XII of 1884.

THE Nizam of Hyderabad is said to have decided to open a School of Agriculture in his dominions, and has applied to the School of Agriculture at Madras to supply him with a duly qualified superintendent.

THE official demands made up to the 13th ultimo, for repairing the damages caused to Government irrigation and agricultural works in the Tanjore, Madura, and Tinnevely districts by the recent heavy rains, amounted to Rs. 33,000.

ACCORDING to statistics compiled in Europe there are 3,985 paper mills in the world, which make 1,904,000,000 pounds of paper every year, half of which is used for printing, and 800,000,000 of it for newspapers, which ten years ago required only 40,000,000 pounds.

AN engine, said to be the smallest in the world, has been made by a watchmaker now connected with a watch-manufacturing company. As described, the engine is of the upright pattern, and is made of steel and gold. It rests on a 25-cent gold piece, and can be worked either by steam or compressed air. The cylinder is a little less than 1-16 inch in diameter, with a little less than 3-32 inch stroke. The balance wheel is ½ inch in diameter, and can make something like one thousand revolutions in a minute. The wrist-plate is a sapphire cut for the purpose.

THE net imports of gold up to the end of December amounted to Rs. 4,36,98,371, and of silver to Rs. 9,44,37,448. The amount of bullion coined and examined at the Calcutta and Bombay mints was Rs. 3,65,84,682, of which sum the Calcutta mint only contributed Rs. 5,27,003.

DURING the month of November last, there were shipped from ports in Sind to foreign ports 2,75,367 bags of wheat, weighing 547,305 cwt., and valued at Rs. 23,35,721, as against 1,90,869 bags, weighing 346,252 cwt., and valued at Rs. 15,45,107, during the corresponding month in 1883.

THE Shanghai papers, alluding to Mr. Macaulay's attempt to establish a trade connexion between India and Tibet, express the belief that the Indian gariens can supply Tibet with teas of ordinary quality at a cheaper rate than China, both because the journey is shorter, and because the Indian article is better at the price.

A COMPETENT surveyor, with coolies, has arrived at Singapore from Madras, having been sent for by the Surveyor-General. We have had a good deal of Ceylon, and are now going to try India, apparently. The party will work in Penang and Province Wellesley, and the Commissioner of Lands Titles went to Penang recently to start the work.

THE experiment of ostrich-breeding in Australia has been successful so far, the owners of 80 birds having already exported several shipments of feathers sufficient to yield a fair profit on the venture. The authorities of the Cape of Good Hope have placed an export duty of £100 per pair on ostriches, so that the Australian breeders have secured their birds just in time.

IN an official report on the damage done along the Madras Railway by the cyclone at the end of November last, the Chief Engineer states that the force of the wind at the Vethalacheru tank was so strong, that several bullocks and an entire flock of sheep were blown into the tank, and drowned. He estimates the velocity of the wind at upwards of 50 miles an hour.

OUR coffee market, says a Ceylon paper, is now well supplied with parcels of good and fine plantation parchment, and at intervals during the recent holidays, there has been a fair amount of business in the better descriptions, which have found buyers at Rs. 42-50 to Rs. 43 f.o.b., and in one or two instances exceptionally bold samples have realized even better rates.

DURING the late inundation at Pondicherry, Monsieur Jumcau, the Chief Engineer to the French Government, received into his bungalow at La Grande Etang, the whole of the inhabitants of the English villages of Erraspett and Ammaucoopum, numbering upwards of 300 souls, whom he supported at his own expense for a couple of days while their dwellings were under water.

BUSINESS in coffee is said to have been concluded for the year, as it has, as if by common consent, been curtailed to the narrowest dimensions both at public sale and by private contract, and only retail quantities have been offered and sold at about the previously reduced value, which is from 10s. to 15s. per cwt. lower than at the same time last year for all good useful and medium home-trade qualities.

THE Governor of Pondicherry has applied to the Minister for the Colonies in Paris for an extraordinary grant of 4,000,000 francs (16½ lakhs of rupees), to meet the charges incidental to the late inundations. The amount, besides providing for the repairs and reconstruction of the roads, bridges, irrigation works, &c., includes a liberal sum for distribution among the ryots and others who lost their property during the floods.

MR. B. RIBSENTROP, Conservator of Forests in the Punjab, is appointed to act as Inspector-General of Forests until further orders. Mr. H. C. Hill, officiating Conservator of Forests, in charge of the Pegu Circle, British Burmah, acts as Conservator of Forests in the Punjab. Mr. E. P. Popert, Deputy Conservator of Forests in British Burmah, acts as Conservator of Forests in charge of the Pegu Circle.

CALIFORNIA fruit-growers have discovered that apricots bleached with sulphur fumes and then dried in the sun are superior to those that are dried in any other manner, or that are canned. They regard this fact of very great importance to the whole State. It enables every fruit culturist, however limited his means, and however small the product of his orchards, to dry his own fruit for market, and makes him independent of the canning factories. It is also stated that fruit can be prepared in the same manner more cheaply than in any other, that its weight is better preserved, and that it is of superior flavour.

THE trade of Kurrahee is rapidly developing. In 1872-73 the total value of imports and exports of all kind was only three-and-two-third crores; in the past year it amounted to very nearly nine crores. The trade with ports on the coast increased during the year by 18½ per cent and the foreign trade by more than 34 per cent.

About half of the foreign trade is with the United Kingdom. Cotton manufactured goods, hardware, cutlery, wire, and wrought brass were imported from England in unusually large quantities during the past year. The value of Indian products exported—which consisted chiefly of wheat, seeds, rawhides, and raw wool—exceeded three-and-a-half crores.

THE price of kerosine oil is still drooping, for the supply is increasing faster than the consumption. From Baku in the Caucasus, there were exported from May to December last year about 3,356,298 gallons of kerosine, and 1,206,621 gallons of lubricating oil. A portion of these products went to the Black Sea and the Danubian Principalities; another went to the Mediterranean ports; a third to Russia proper and Germany; and a fourth to Persia and the Red Sea ports. It is locally expected that in time Baku naphtha products will find their way to Saraka, Herat, and Candahar. It is asserted that the Baku springs are believed to be capable of furnishing 250,000,000 gallons of oil a year.

It has often been a cause of wonder why the fine flavoured cocoa grown in the island of Trinidad was not manufactured into chocolate on the spot, instead of being all sent to Europe for that purpose, and returned there in that form for their own consumption at a much higher price, and to a certain degree of deteriorated quality. The problem has at last been successfully solved by the manufactory established there under the management of Mr. J. Schaeffer. With the appliance of the latest and best description of machinery chocolate of the choicest quality is made in Port of Spain from the finest cocoa grown in Trinidad and Venezuela, equal in every respect to the Menier brand which has acquired such world-wide reputation.

MUCH dissatisfaction is felt among the Covenanted portion of the French Government officials at Pondicherry, at the reduced rate, for converting the franc into rupee currency, which has been fixed by the Council-General. Hitherto the price has been francs 2-40, but for the current year it is to be francs, 2-06, being a reduction of 14 per cent, which means, practically, to a large number of employees, so much less pay. The case seems to be a very hard one, and is unsupported by any precedent in the administration of the Pondicherry Government. The salaries and allowances are given in francs, and should be paid in that coin, or the current equivalent in rupees. The action of the Council in reducing the value of the franc is looked upon as not only unjust, but illegal.

THE *Madras Mail* says:—"We may some day obtain prime fresh Australian meat in Madras. The *S. S. Caterthun* sailed from Palmerston, in the Northern Territory of Australia, last month for Hong-Kong, with a trial shipment of ten bullocks each for Batavia and Singapore. A champagne spread was given on board, when the Government Resident enquired the exporters. He said that they had now made trials of the market of Hong-Kong, Batavia, Singapore, and would anxiously and hopefully await the result. The pastoral development of the territory largely depended on the Indian and Eastern markets. There were myriads of consumers within three weeks' steam, and let a taste for Australian beef be created, and there would be no limit to the possibilities of the trade."

Selections.

BEE-REARING.

From J. C. DOUGLAS, Esq., to the Secretary to the Government of India,—dated 9th January 1885.

I HAVE the honour to report, for your record, the results of my agricultural observations during the past year.

2. I commenced the year with two stocks of the variety of *Apis indica* indigenous to Lower Bengal; one of these was a swarm I captured near my office at Alipore. As the weather became warm, these bees built comb, and they worked out artificial comb foundation, specially made for them from an engraved plate; from the rapidity with which they worked at the commencement of the season, I anticipated they would prove of value. Before, however, they had half filled their hives, they prepared to swarm, bred drones and queens, and I divided the two stocks into four. These did well, but I got absolutely no surplus honey. I took a few ounces, but I had to feed much more.

3. The variety of *Apis indica* is kept by villagers; they do not cultivate it at all, but merely encourage the bee by inserting earthen vessels in the house-walls, and they take the honey by taking all the combs, so that the stock perishes. I have received many estimates of the quantity of honey obtained, but they differ widely and are quite unreliable. Having taken many stocks and purchased others, and having kept the bee during two seasons, I am of opinion that it is commercially valueless. Possibly 5 or 6 pounds of honey might, under exceptional circumstances, be obtained by sacrificing the bees, but this is obviously insufficient to repay cultivation. This estimate is confirmed by an account of the cultivation of *A. indica* in Ceylon,—*Journal, Ceylon Branch, Royal Asiatic Society, Volume VII, Part I, No. 23*. Of the stocks, I had I gave one to a station master on the East India Railway and one to a native gentleman; both these are in hives. Mr. Stocks, of Berhampore, has a stock, from which he recently took half-a-pound of honey with an extractor. Mr. Stocks being favourably situated and having the appliances will further test the value of this bee under the most favourable circumstances. This bee is not so easily handled as good-tempered Italians, but is as easily managed as the European Black bee, and is better tempered than the cross between the Black and Italian.

4. This bee is valueless, because—(1) its stocks are too light in comb and bees; (2) it swarms too frequently, so that without trouble and much attention only very small hives can be filled; (3) the surplus honey is very small in quantity; (4) the bees do not

defend their hive against moth and other vermin, so they readily succumb to the moth, particularly during the rains.

5. Another variety found in Bhutan, building $5\frac{1}{2}$ cells to the inch, appears far superior to the variety found in Lower Bengal. Captain R. Fulton, B.S.C., stationed at Buxa, has kept this variety. He gave me two stocks, one of which was very weak and failed; the other I have under observation. Captain R. Fulton also gave a stock to a gentleman at Barrackpore. This variety is larger and builds larger cells than the varieties found in the plains, Chumba, and cultivated about Mussoorie and elsewhere. I am informed its stocks are sufficiently heavy, but I have no data from which to judge of its commercial value; on this point I shall be able to give an opinion probably by the end of June next. This variety of species is, I believe, undescribed; the stock I have is exceedingly mild in disposition, the workers go out very early, and they readily use the comb of the Italian bees slightly contracting the cell by their outer edge, but they have the failing of not keeping their hive clear of vermin, particularly moth, which they suffer to live unmolested apparently on the floor-board of their hive. Should this variety prove of value stocks can be readily obtained, but I am decidedly of opinion this variety is very inferior in value to the Italian bee, even though it may prove sufficiently valuable to warrant its cultivation.

6. The variety found cultivated at Bushahr by Mr. Minniken appears to me equal to the European hive bees in productiveness; it is closely allied to the European species, and appears somewhat larger in size; whether it can be readily handled, whether it defends itself against moth and other vermin, and whether or not it swarms to such an extent as to reduce its value, can only be ascertained by observation. This variety or species is, I believe, undescribed. I am of opinion measures should be taken as early as practicable to ascertain the economic value under cultivation of this species. I have written to Mr. Minniken on the subject, and I now send two boxes with instructions for packing two stocks of these bees, which I should like to receive as early as practicable to admit of their being observed during the coming season, provided you are pleased to obtain them for me.

7. As to the possibility of cultivating the Italian bee, I am now quite convinced it can most certainly be cultivated here. I brought out five queens, of which I saved two, and in 1883, these two filled their hives, although they had at first but a few hundred bees; I had nursed these into strong stocks, when one of the queens died; I had no drones, and the rains prevented drone breeding. I had therefore only one stock left. I wrote for four queens, and these were sent by Sir G. Birdwood, but only two arrived alive; one of these became diseased, and I had to destroy her. I again sent for four stocks direct from Milan; of these I saved two queens, which are doing well. I bred a queen, the first bred in India; this queen is doing very well; her stock is very vigorous. I was obliged to remove it from the apiary as it attacked another stock, and robbed it of all its stores. I have now five queens with bees; the stocks are still weak, but I have no doubt whatever I shall be able to distribute during the coming season queens and bees to perhaps a dozen persons who are prepared to receive them. One of the queens was born in 1882; she is now $2\frac{1}{2}$ years old at least, and has been in India more than two years; she has furnished bees and brood for all the other queens, and to keep up diseased stocks, and last year I took 15 lbs. of excellent honey from her stock, which, as it was kept in Park-street, Calcutta, had very little opportunity of furnishing a rich harvest. I found the bees did exceedingly well; they kept their hives clear of wax moth and other vermin. I found two deaths—head moths in one hive, evidently destroyed by the bees. I find the bees can get pollen all the year round; it was feared they might not get anything in December and January, but they get almost too much pollen during those months; they are getting honey now.

8. The largest yield per stock I have had reported for *Apis indica* is 30 lbs. of honey; this is reported by Mr. Seymour of Mussoorie. This gentleman has kept bees for several years in Australia, and his testimony is therefore of considerable value. He thinks bee-keeping with *Apis indica* as found about Mussoorie very inferior economically to the culture of *A. mellifica* in Australia. Setting aside such figures as 500 and 600 lb. per stock, in America G. M. Doolittle, an apiarist of great experience, considers 50 lbs. of comb honey or 75 lbs. of extracted honey an average crop per stock. Thirty-one Canadian bee-keepers had 1,484 stocks in the spring of 1884; increased to 2,569 stocks during the year; they took 37,250 lbs. of comb honey and 59,845 lbs. of extracted honey. I think one pound of comb honey equal to quite 1½ lbs. of extracted, and so estimated, the yield as above was equal to an average of 80 lbs. of extracted honey and an increase of 90 per cent in stocks of bees. The crop of the year was considered scarcely up to the average. The severe and long American and European winters render apiculture more precarious than in the plains of India, or even in the hills. The great superiority of *A. mellifica* over *A. indica*, and the importance of acclimatizing the former is apparent; the Bushahr bee might prove as productive as, or more so than, *A. mellifica*.

9. I could have distributed stocks last year had I wished, the one queen would have supplied bees, queens, and drones, but I preferred to import other queens rather than breed in and in. The journey from Europe is very injurious to the queens; even those which appear to arrive in good health are commonly found ultimately to have suffered in their laying powers, or to have become diseased. Knowledge of this fact induced me to import a number of queens in the hope of saving a few, and the ignoring of this has caused the failure of all previous attempts to introduce the European bee into India.

10. During the year I have issued a number of hives and other appliances to persons anxious to take up apiculture in different parts of India; these persons are practising and learning on *Apis indica*. The issue of Italian bees during the coming season will, I

have no doubt, confirm these persons in their resolves, and spread the practice to many others. The Italian bees will be issued to bee-keepers in British Burmah, Assam, Orissa, Bengal Proper, Mussoorie and Dehra, Bhootan, and elsewhere.

11. As to the natural history of Indian bees of the genus *Apis*, very little is known; several varieties of *A. indica* and *A. dorsata*, and *A. florea* have been described, but there is much confusion in naming them; in most cases the descriptions are incomplete, not including the descriptions of drone, queen, and comb; the life history has not been studied, and some Indian honey bees have not been described at all, being quite unknown to European naturalists. In 1862, Dr. Gerstaecker of Berlin discussed the classification of Indian honey bees in a paper read to the "Wander-Versammlung Deutscher Bienenwirthe," and he pointed out the confusion that existed in nomenclature and excellent grounds for a classification so far as the available knowledge admitted. Since the decease of the late Mr. F. Smith, I am informed there is no member of the British Museum staff specially qualified by knowledge of this genus of insects.

12. In my little Handbook of Bee-keeping for India, I described a typical *A. indica*, and omitted all mention of the varieties and their synonymous names. I am about to carefully examine the collection I have, and I hope to obtain other specimens. Specimens, particularly if including the drone, queen, and a small piece of comb, would be of great service. I have no doubt, whatever, I shall be able to add considerably to the existing knowledge of Indian honey bees and their life history, as well as discover some of economic value; in both the Bhootan and Bushahr bees, it appears probable insects of economic value have already been discovered; it remains to decide by observation how these compare severally with the Italian bee now rendered available.

13. As I am about to examine, compare, measure, and describe all the Indian honey bees of which I can obtain specimens, and also to endeavour to discover their affinities and the bearings of these on the origin of the European hive bee, which probably originated in Asia, and as I may not only be able to indicate the best variety and best mode of cultivating it for the benefit of the natives of India, but I may also obtain information of economic and scientific importance to European and American apiculture, I beg that any spare specimens of the number collected by Dr. G. Bidie may be sent to me.

Instructions for transferring and packing Bees in portable Hive.

SMOKE the bees slightly, spray them with thin syrup unless they have honey accessible in their combs; then with smoke, by shaking and brushing the bees from the combs remove the combs one at a time. Fit the combs into the frames against the top bar, cutting the top of the comb straight, if necessary, and filling up the frames with pieces of comb, if available. The wire-fixers are for holding the comb in the frames while tying it in. Tie the comb in the frames by stout twine at every two inches vertically and horizontally. Very white new combs should be rejected; very thick heavy combs containing much honey and sealed may, be pared with a knife to one inch. The brood combs, if any, should be placed in the centre frames. If there be much honey in the combs, other food may not be necessary, but full combs travel badly, and food may be given by mixing honey and crushed white sugar to a stiff paste and filling the food-box with it. The water bottle should be filled and so corked that the water does not come out unless the bottle be shaken.

2. The combs having been transferred, shake or brush the remaining bees into the box, close carefully with cloth or by other means the ventilators of the box, cover the top and open the door; place the portable hive in the place of the old hive. The portable hive with its entrance, as far as practicable, with some place as the entrance of the old hive should be left till evening; after dark, when the bees are all in, the door should be closed, the ventilators opened, and the box despatched.

3. If the weather be very cold, the side ventilators may be partly covered, but otherwise they should be left quite uncovered. One brood comb at least should be inserted, if possible, even if from another stock, as the presence of brood prevents absconding.

4. If detained on the road, the bees may be allowed to fly, the door being opened, and closed again after dark. *Whenever the door is opened, the side ventilators must be completely closed.*

Unless the boxes are to be closed longer than a week, it would not be desirable to open the hive boxes *en route*, and then only if some one is present who could hive the bees if they swarmed out.

5. It will be found convenient in transferring to remove all the frames from the box and put the lid on; as each comb is out of the old hive, brush the bees from it into the box and put on the cover; if the principal cluster be gently lifted and shaken into the box, there will be no fear of the queen having been left behind.

See also "Driving" and "Transferring" in the Handbook of Bee-keeping for India.

6. The boxes contain a veil, smoker, spray diffuser, and one dozen comb fixers; the articles should be retained excepting the latter, which may, if necessary, be left in the comb, but should, if practicable, be removed.

THE SIBI HORSE FAIR.

[FROM A CORRESPONDENT.]

THERE has been an unusual stir and bustle about the sleepy little station of Sibi, and the bazaars are once more as crowded as they were in the war time. But now the gathering is a peaceful one. The Government Horse-Breeding Department last year discovered what a grand field they had amongst the Beluchis. The active Superintendent, Mr. Grainger, came to Sibi and Quetta, saw some hastily collected mares, branded about 150, and sent to Beluchistan three stallions. This year a fair was started

by the Political Agent, Mr. R. J. Bruce, C.I.E., and considering that it is a first attempt, it must be reckoned to be a great success. I understand the Veterinary Surgeons present declared that they have seen no such collection of mares before on this side of India.

The Agent to the Governor-General is here, and several officers belonging to the Cavalry Corps in Biluchistan. I observe also some of the Biluch chiefs from the Punjab were present as well as many other Kibzai, Kakar, and Musakhel sirdars. These latter come from Thul Chotiali, accompanied by the Assistant Political Agent, Captain Gaisford. Of course the Horse-Breeding Department is fully represented, but there is a great absence of buyers, only two regiments having sent officers to purchase. This is to be accounted for by the very short notice that was given about the Fair. When it is known how good these hardy mares are, there can be no doubt that there will be an immense demand for them. The chief's camp on the Sibi plain where the Political Agent had arranged tents for them, instead of their having to search for quarters in the town of Sibi, was very picturesque. On the 12th instant, nearly everybody had arrived, and the horses were classified. This was no easy job, as all were new to the work, and the exhibitors had not the smallest idea of what was wanted. The inexhaustible energy of Rai Bahadur Hitu Ram, the Native Assistant to the Governor-General's Agent however, worked wonders, and in the afternoon everything was ready. The next morning the judging commenced, and as many people would probably like to know the numbers and descriptions of animals shown, a rapid survey of the various classes may be acceptable. Class I. was for branded mares, over four years of age and over 14-1 in height. For this sixty-nine contended for the ten prizes, valued at Rs. 400. Nearly all these mares were good ones, and the ten that were finally left in the ring would be very hard to equal in India. The winner was a big blood-looking mare, about 15-2, with a foal at foot (three days old) to the grand waler *Blue-light*.

Class II. was for unbranded mares, over four years old and over 14-1 in height. This class was very well represented. There were fifteen prizes, aggregating Rs. 515. For these no less than 320 mares entered, and the judges had a very difficult task. All the prize winners were large, roomy, big-boned mares, the three first being especially good specimens.

Class III. was for branded mares 14-1 and under, and over four years. For this there were only three entries, two of which were awarded prizes, value Rs. 35.

Class IV. was for unbranded mares 14-1 and under and over four years old. This was only fairly represented. Nine entries, 4 prizes, value Rs. 100.

Class V. for fillies, three and four years of age, was well represented, forty entries, four prizes, value Rs. 100.

Class VI. Colts, three and four years of age, 30 entries, four prizes, value Rs. 115. These were a poor lot, but as it is desired to encourage the zemindars to raise colts, the rewards were liberal.

Class VII. Fillies under three years old, five prizes, value Rs. 145. For this, twenty eight very nice youngsters were paraded.

Class VIII. Colts under three years old, four prizes, Rs. 75, twelve entries, again a bad lot.

Class IX. Horses over 14-1 and over four years, four prizes, Rs. 150, fifty entries; a very poor lot.

Class X. Geldings, five entries, Rs. 75; a wretched show, but the prizes were given *pour encourager les autres*.

Class XI. Native country-bred horses that had been used for covering, 35 entries, prizes withheld. There was a considerable commotion in the ring as these brutes were led round. Most were unsound, and all were coarse and underbred-looking. However, these are the animals used in the district, and their exhibition ought to incite the Horse-Breeding Department to send a sufficient supply of good stallions without delay. It is ten thousand pities that the splendid mares of this country should be mated as they now are.

There were thus Rs. 1,785 awarded in prizes, and fifty-six horses were judged by the Committees. The judges were Major Carr, 5th Punjab Cavalry; Mr. J. E. Grainger, head of the Remount Department, Bombay; Veterinary Surgeon Raymond, Quetta, and Captain Gaisford, Assistant Political Agent. Ten remounts were purchased at an average of rupees one hundred and eighty. These will doubtless be found very cheap buys, and prove most useful horses. To those who have not yet seen the Biluch mares, it may be explained that their chief characteristics are hardness and endurance. They are nearly all good-tempered, have generally plenty of bone, and very few of them brush. Nearly all are unshod. If mated to short backed, compact horses, with blood and action, their produce would be very valuable. Giving prizes for geldings is at the best but a half measure. As horse-breeding operations are being started afresh, it would be a splendid opportunity to try the oft-suggested remedy of putting a tax on stallions, although perhaps such a measure could not be introduced under present circumstances into Biluchistan.

On the 14th instant the races came off: and to the Biluchis this was by far the best part of the Fair. Unfortunately the morning was a wet one, and as the clouds looked like "staying," it was determined to run the races off as soon as possible. Notwithstanding the drizzle there was a large concourse of natives, and all the sirdars were present. The course was very heavy and a little over two miles long. The Biluchis, however, complained that it was not nearly long enough, and suggested that four miles was the minimum it should have been. Seventy-six starters went to the post. They were divided into three heats. The winner of each was to get Rs. 50, and the first four of each heat were to compete for the final contest. Most of the mares had been trained very fine, no grass whatever being allowed for the last three days, but unlimited gram. The jockeys wore their ordinary clothing, and rode barebacked with ring-snaffle

bridles. As soon as the first start was effected, it was evident there was to be no mistake about the pace. The "flushing" commenced after the first hundred yards. The jockeys stuck to the mares like wax, and kept up a shower of blows, with a very light whip however. The horses ran very gamely, and came along at a really good rate. The winner of the first heat was a blood-looking four-year-old mare, got by a Jacobabad Government Arab, the property of Sirdar Shah Baz Khan, chief of the Bugti tribe. Notwithstanding the distance and the heavy course, none of the animals appeared any the worse for the great exertion they had undergone. After the three heats had been run off, the clouds looked still more threatening. The final heat was to have been run off in the afternoon, just before the Governor-General's Agent's Darbar, but all the winners petitioned that it might be settled forthwith. The winners of the last heat had barely time to catch their wind before they were walked back to the starting post. The pace of the final race was every bit as fast as the others. The result was that the Arab-Bugti mare again won, whilst the second, a horse, was also half Arab.

Rain having fallen on the afternoon of the 14th, the Darbar was postponed until the 15th, when the prizes were distributed by the Governor-General's Agent, Sir Robert Sandeman.

I may add that among the visitors attending the fair, I noticed Colonel Sir R. Sandeman, K.C.S.I.; Mr. R. J. Bruce, C.I.E.; Major Plowden; Mr. H. Barnes, C.S.; Captain Hope; Captain Melvor; Major Armstrong, 5th B.C.; Captain Jackson, 1st Bombay Lancers; Mr. Murray, 17th Regiment; Dr. Fullerton; Captain Wahab R. E.; &c. &c.

The Khan of Khelat also sent his chief minister, Nawab Mahomed Khan, and a batch of mares and stallions. A diploma was given to the Khan for two mares and two country stallions.—*Pioneer*

DEODAR PLANTING.

As an old Forest Officer, and one who has done a great deal of deodar planting, I trust I may be excused if I say a few words about the system adopted in Kulu, and described at page 466 of your number for October. I quite agree with the employment of boys. I have always found them much quicker in learning and smarter in planting than either men or women; but as regards the Kulu method, I am sorry to say I cannot see the use of it, and think it must certainly be much more expensive and slower in execution than the system of planting in holes. In the first place I have always found that young deodar of 20 months old are quite strong enough to be planted out, they are then 9 inches high (if below that, I never put them out), and I see no use in keeping them in the nursery another year; this, however, is a fault on the right side; the parts of the Kulu method to which I would take exception are, the trench and the number of plants used. Of course lines must be cut through the jungle, otherwise no planting could be done. I therefore pass on, merely remarking, that in my opinion, 10 feet between the lines is too far. Deodar should be planted in lines not over 5 feet apart; there is no doubt they thrive better and throw out less branches when they are grown close together, and as they are found in dense thickets growing naturally, we can do no harm in this case in following nature. As regards the small trenches made in Kulu, it appears to me that they must be at least four times as expensive as holes, and as four plants are put in a space of 2 feet, it stands to reason that there is a waste of three plants, for it is impossible for four trees to exist 6 inches apart. I hold that as it is quite possible to plant deodar in holes 5 feet apart without 10 per cent of loss; it is therefore sheer waste of material, time and money, to dig small trenches 2 feet long, and put four plants within the 2 feet. As for the little dab of mud to stick the plant against the wall, I see no harm in it at all. I am sure many officers must have seen continuous lines of deodar, planted simultaneously, as in the Kalatop Forest, near Dalhousie; as therefore, it is possible to plant successfully at 5 feet apart in holes, I cannot see the use of an expensive trench and the waste of three plants. When I planted deodar in former years (and I have done it with less than 10 per cent of loss), I worked as follows:—Lines were cut through the jungle, where necessary, at about 5 feet apart, then men with "pharwas" cut deeply into the soil three or four times, at points 5 feet apart in the lines, whilst after them came boys or men with "kharpas," who dug the hole to the required depth, leaving the loose soil on the lower side; this was done some days or even weeks before the actual planting took place. Planting was done by boys who had been carefully trained to the work; the plant was held at the required height above the bottom of the hole so that the end of the root was not bent or curled upwards; this was then fixed in the earth with a lump of mud, and loose soil from above the hole gently crumbled about the roots and gradually pressed down all round. I consider this plan far simpler than the Kulu one, less expensive, and one that does not require such careful supervision, all of which are of great importance to a Forest officer who cannot always be present when planting is going on. There is really no more difficulty in planting a deodar than in planting a cabbage; the principal things required are that the root shall not be injured in taking out of the nursery, and shall be fixed properly in the earth when planted out. To conclude, I have no doubt the Kulu method gives excellent results, but I maintain that it is a tedious and expensive one, and as long as single plants can be successfully planted out at 5 feet apart in holes, it is quite unnecessary and wasteful to put four plants in a space of 2 feet, seeing that at some time or other three of them must be lost.

G. SPARLING,
Retired Deputy Conservator of Forests,
late of Jhelum Forest Division.

Dalhousie, 31st October, 1884.

—*Indian Forester*.]

SECOND FORECAST OF THE WHEAT CROP OF THE CENTRAL PROVINCES, IN SEASON 1885.

From J. B. FULLER, Esq., Director of Agriculture, Central Provinces, to the Secretary to Chief Commissioner, Central Provinces.—Dated Nagpore, the 27th January 1885.

SIR,—In continuation of my No. C 160 A., dated 17th January 1885, forwarding a copy of a telegram despatched to the Government of India on the prospects of this season's wheat crop, I have the honor to submit a more detailed account of the condition of the wheat crop up to the middle of the current month.

2. As mentioned in my letter above quoted, the orders calling for the submission by District officers of a forecast on the 10th January did not formally cancel previous orders under which a forecast was due from them by the 15th January, and I expected that the forecasts for the 13 districts, from which none were received, dated January 10th, would arrive by January 15th. But up to January 20th forecasts were still outstanding for six districts, including the important ones of Nagpore, Raipore and Bilaspore, and I have been unable to include particulars for them in this return. Under the orders contained in Circular No. 39, dated 4th November 1884, the forecasts submitted in the middle of January were to be accompanied by reports from District Councils, but these have been received from only the two districts of Seoni and Betul.

3. Statistics of the area under wheat have only been received from one district (Hoshangabad) and the Deputy Commissioner distrusts their accuracy. Until indeed the reform of the village record staff has been completed, no area statistics of any value can be expected from these Provinces. General enquiries seem to show that there is a decrease in wheat area of larger amount than I anticipated in my first forecast dated December 19th last, and judging from the reports now received the area in the northern districts is less than the normal by from 15 to 25 per cent. The largest decrease is that reported from Wardha which amounts to 32 per cent. A special report on the causes of this has been received from the Districts of Chuttagurh no

reports have been received, but I do not think from what I have seen in the Raipore district that the decrease in area amounts to more than 15 per cent.

4. The late falls of rain have been of immense benefit. In the last week of December there was a fall ranging, roughly speaking, from 2 inches in the southern to half an inch in the northern districts. Since then more rain has fallen in the north of the Provinces, where more was needed. The district estimates show in many cases a substantial increase over those received in December. In Saugor only a two thirds crop is anticipated and in Hoshangabad even less than this. But these estimates are probably rather under the mark, and, speaking generally, an outturn may be anticipated of from 80 to 85 in 100 in the north of the Provinces and from 90 to 95 in the southern districts. Perhaps the best proof of the favourable character of present prospects is afforded by the fact that the monthly price currents which are received in my office from the towns of Jubbulpore, Harda, Nagpore and Raipore show that the price of wheat is very considerably less than it was after last year's harvest. The figures are as below :—

		PRICE PER MAUND OF 80 SEERS.					
		May 1884.			December 1884		
		Rs.	As.	P.	Rs.	As.	P.
Jubbulpore	...	1	11	11	1	9	7
Harda	...	2	1	4	1	15	4
Nagpore	...	1	12	10	1	9	10
Raipore	...	1	5	6	1	1	8

The high prices of last year may no doubt be attributed to the activity of the export trade. But the export of wheat has by no means stopped during the past three months. From October 1st and December 31st, 1884, the wheat exports of these Provinces amounted to 15½ lakhs maunds.

District.	Percentage by which area under crop exceeds (+) or falls short of (—) the normal.	Explanation of difference in area.	Estimated outturn in annas per rupee taking 12 annas to represent normal outturn.	Reasons for estimate.
Saugor ...	—20	The incessant rain prevented the preparation of the whole area. Its early cessation allowed the ground to harden before sowing time.	8	The crop is progressing favourably. The rain of the last week of December, and that which has fallen since has been of great benefit.
Damoh ...	—10	As above.	Not stated.	A good crop anticipated.
Jubbulpore ...	+ 5	The heavy rain prevented kharif sowings, but was favourable for wheat.	13	Prospects good. The recent rain has been of great benefit.
Mandla	No return received.
Seoni ...	—20	Same reason as given for the decrease in the Saugor and Damoh districts.	11	The seed was sown under unfavourable circumstances, and hence outturn is estimated as less than the normal. Prospects have improved lately.
Narsinghpore ..	—25	As above.	11	...
Hoshangabad ...	Not stated.	Area less than the normal owing to early cessation of rains.	From 7 to 10 annas.	Sowings have germinated well. Outturn estimated at seven annas in two out of the four tahsils, and at ten annas in the remaining two.
Nimar ...	+5 in one tahsil.	Wheat has been sown on land on which the autumn crops were ruined by rain.	12 in one tahsil.	The late rain has greatly improved prospects.
	+25 in the others.	14 in the others.
Betul	10 to 11	Estimate has been raised in consequence of late rain.
Chindwara ...	+ 2	9	The crop at first appeared poor, but has been greatly improved by the late rain.
Wardha ...	—32	Area has decreased owing to the abnormal character of the rainfall.	11	Estimate has been raised in consequence of the late rain.
Nagpore	No return received.
Ohanda ...	—15	Same reason as that given for the decrease in the Saugor and Damoh districts.	8	Germination has been unequal.
Bhandara	No return received.
Balaghat ...	—10 in one tahsil.	12	Prospects are good.
	+6 in the other.		
Raipore	No return received.

WATER FILTRATION.

RESIDENTS in the East have only too frequent opportunities of learning, by unpleasant, and even fatal experience, the dangers of impure water, and the advantages of perfect filtration. So many domestic filters are unfortunately merely so many delusions and snares, that their use positively increases the very dangers which they are employed to avert. The household water-filters until lately in use have generally been made of sand, coarse charcoal, or other similar material, cemented down or moulded into blocks. Now sand cannot remove the finest impurities, and neither can coarse charcoal; because the voids between the various particles of filtering medium are too large. The coarsest impurities are indeed arrested, but as in most of the filters alluded to, the filtering medium cannot be got at or removed by the householders themselves, the very impurities which are arrested are nursed and developed therein until the whole mass is teeming with life, which gradually finds its way into the filtered water chamber. Evidence of this appears when the water tastes mawkish, or flat, or when small white filers can be seen in the filtered water; but long before this evidence is forthcoming, the filter has ceased to be anything but "a delusion and a snare." So-called charcoal blocks are not made entirely of carbon; clay, tar, and other coagulative materials are used to hold the charcoal together. Regular pores and channels are opened in the block during the baking operation, and the corks and glass fittings used with them are very often faulty. Moreover, the interior cannot be got at for cleansing, and this is a fatal objection to their use. You may blow through the block, the air will pass through the more open pores; but not through those that are choked with organic matter; you may scrape and brush the surface, you cannot remove the filth that is inside the block. It is not unusual to hear of such charcoal blocks being broken open, and found to contain live maggots and small red worms. Indeed, the writer on more than one occasion found maggots, &c., in the filtered water of one of these block-filters in India, notwithstanding that he frequently had the filter scalded out with boiling water. "But," says one maker, "my filters are self-cleansing;" "they require no attention," says another; "it will suffice to reverse the current," says a third; "or to blow through the filtering medium," says a fourth. Can anyone who has given the subject the slightest thought believe these extraordinary assertions? Break up one of these filters after it has been so "self-cleansed," and examine it. Often, a filter is left out of use for months, say in the absence from home of the family; it has, perhaps, been left partly filled with water all this time; judge what the condition of that filter must be when it is again being used, without having been taken to pieces, and without having had the filtering medium changed. A filter is like a dust-bin; it must be looked after and cleansed periodically. It is better to have no filter at all than to have one that you cannot or will not take the trouble of cleaning. We have of late years been told to boil the water we drink; but now Dr. Frankland says that "the germs which propagate epidemic, or zymotic diseases, may be boiled three or four hours and yet not be destroyed; they continue to exist in an atmosphere of cyanogen, they get on very well in sulphurous acid, in fact there are very few poisons which affect them." Cheerful news, very, to many of us, who in times of epidemic in the East have taken such care to have our water boiled! There is, therefore, but one remedy—it is to separate the germs, &c., from the water by a perfect system of filtration. To be perfect, a water filter must not contain any material which can communicate any injurious or offensive quality to the water which passes through it. It must remove from the water not only all the suspended matter—even the smallest bacterium or bacillus—but also organic matter in solution and inorganic matter in solution, such as iron or lead. It must aerate the water during filtration, and be so constructed that the owner himself can take it entirely to pieces, throw away the old filtering medium which has done its work, and replace it with a new charge with little trouble, and at a very small cost. Such are the qualities possessed by Maignen's patent "Filtre Rapide." To mark their approbation of this invention, the Special Commissioners, appointed by her Majesty's Government at the late International Fisheries Exhibition, awarded a gold medal and two diplomas of honour; the Sanitary Institute of Great Britain, a special medal of merit, the only medal ever given by the Institute for filters; the National Health Society, a silver medal, their only award for filters also. This filter has been selected by the War Office for the Nile Expedition, both for the service of the boats, and for field hospitals. It has also received the approval of the French and Belgian sanitary authorities. The last pattern of Maignen's filters approved by the War Office is just the size of an old-fashioned watch, and can be used with an india-rubber tube to draw water from a pond or as a syphon, a more complete description of which we will give later on. Filters on the Maignen principle are made in all sizes from the "Tourist" and "Pocket Filtre Rapide," measuring 6 by 3½ by 2 inches, and weighing, when full, 2lbs. 2ozs., or empty, 1lb. 2ozs., up to filters capable of supplying a town with pure water. We have not space to describe the construction and process of charging these filters; suffice it that they are strong, elegant, easily cleansed and easily charged, and above all things, effectual. For those who desire to obtain valuable information on water filtration, the reducing hard water to soft, and on water generally, as well as particulars on the various forms and details of construction of the Maignen filter, we would recommend a very readable pamphlet, entitled *Water, Preventible Disease, and Filtration*, by P. A.

Maignen, and published by P. A. Maignen, 32, Mary-at-Hill, Eastcheap, London, E.C.

Apart from his filters, Mr. Maignen has introduced a most simple and effective means of softening hard water. Hard water is injurious for drinking, because its power as a solvent for the food is impaired, and because it is taken up by the absorbents of the stomach with much greater difficulty than a soft water, thus impeding digestion. It is a notorious fact that persons liable to gout or stone are well in soft-water districts, but they become very ill as soon as they go to live in hard-water localities. In making tea or coffee, cooking vegetables or stews, the difference between hard and soft water is very great. If tea be made with soft water it is much stronger and requires much less sugar than if made with hard water, thus effecting economy in both tea and sugar. Hard water is also very bad for washing. Each "degree of hardness" (i.e., each grain of solid matter per gallon of water) causes the destruction of 12lbs. of the best soap by 10,000 gallons of water. With London water there is a loss of about 2lbs. of soap for every 100 gallons of water used before any portion of the soap can act as a detergent. This has led to the employment of soda and washing powders, which often spoil the linen, settling on it with the tenacity of a mordant, injuring both fibre and colours. In cases of diseases of the skin hard water is a veritable poison. Hard water produces the crust in kettles and boilers. It has been computed that 1-16th of an inch thick of incrustation causes a waste of 15 per cent of coal; ½ of an inch 60 per cent; and 1 inch 150 per cent. This is a very serious item when coal or fuel is expensive. By throwing a given quantity (easily ascertainable) of Maignen's "Anti-calcaire" powder into the water, the lime and other matters are thrown out of solution, and they then subside, forming a stratum at the bottom, and the softened water can be run off from a tap placed a little way up the vessel's side above the deposit. This "Anti-calcaire" process can be applied in ordinary water jugs, or on the largest scale. For fuller details on this branch of the subject, we must also refer our readers to the above-mentioned pamphlet.—*Home and Colonial Mail*.

THE COOLIE RIOT IN TRINIDAD.

It is almost a matter of course that there should be wide differences of opinion here, in London, at least, about the causes which led to the collision between the police and the coolies at San Fernando, and who is to blame for the deplorable loss of life occasioned thereby, but, as the whole affair is still *sub judice*, and seems likely to be further investigated by a special commission sent out from home, we think our readers would do well to suspend judgment until these official inquiries have been completed. Mr. Qulutin Hogg, Acting Chairman of the West Indian Committee, has done good service to the Trinidad planters, by promptly writing to the *Times* to point out that "there is no justification whatever for the attempt made to represent the riot as having arisen from any increase in the daily task, or in any reduction in the daily wages," and that the "insinuation that the riot arose from an attempt to interfere with the religious rites of the coolie" is equally uncalled for.

In the House of Commons, on December 4th, in referring to the subject, Mr. Ashley said that for many years the celebration of the Mohurrum festival had been attended with more or less disturbance among the coolies in Trinidad, collisions having taken place between the bands from different estates, resulting in bloodshed. In 1882 an ordinance was passed, based on a British Guiana ordinance, which is said to have worked well, under which, in the earlier part of this year, regulations were issued by which the processions were forbidden to enter the towns of Port of Spain or San Fernando, or to use any high road without permission. It was fully explained to the Indian population that the regulations were merely intended to preserve order, and in no way to interfere with the celebration of their religious festival. Notwithstanding this, the coolies marched on 31st October, in large numbers, estimated at 1,000, armed with hakka sticks and cutlasses, and attempted to force their way into the town of San Fernando. The police were drawn up, with a small number of soldiers behind them, and the coolies continuing to advance after being repeatedly warned, the Riot Act was read, and the police fired. Thirteen coolies were killed and eighty-nine wounded. The Inspector-Superintendent of police stated that the police fired in self-defence, and in his opinion, and that of the officer commanding the troops, they would have been overwhelmed had they not done so. These are the facts as reported to the Colonial Office, but considering the great loss of life, the Secretary of State considers that an inquiry by an independent person will be desirable. It is important to note that the Colonial Office has no information of any discontent among the coolies in consequence of alterations in the scale of payments to them. From a table in the last report of the Protector of Immigrants it appears that less than half the coolies in Trinidad were under indentured contracts. Mr. Ashley is not in a position either to affirm or deny that the conditions of the contracts have recently been more strictly enforced, but he says he cannot conceive that there is any possibility of any breach of contract having been sanctioned.

To one point, however, we would call the attention of the public, and especially of those Members of Parliament who have constituted themselves the representatives of the West Indies. There has been no Governor in Trinidad for far too long a time, and no independent administrator since the death of Sir Frederick Barlee some months ago. Government has since been administered by Mr. Baake, who was appointed Colonial Secretary of Trinidad no

INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA :—SATURDAY, FEBRUARY 14, 1885.

[No. 7.]

Crop and Weather Report.

[FOR THE WEEK ENDING THE 4TH FEBRUARY 1885.]

General Remarks.—Rain has fallen throughout the Punjab and the North-Western Provinces and Oudh, and in many districts in Bengal and in Assam. Slight rain has also fallen in places in the Central Provinces, in the Central India and Rajpootana States, and in Chingleput and Hyderabad, and in Tavoy in British Burmah.

Harvest operations continue in several districts in Madras; the outturn is generally below the average. More rain is still wanted in Bellary, Anantapore, and parts of Kurnool; elsewhere prospects are reported to be fair. In Mysore the crops are in fair condition, but future prospects depend upon early rains. In Coorg the situation is the same as last week.

In Bombay the *rabi* harvest has commenced in places, and the condition of the standing crops is generally good. Scarcity of fodder and drinking water continues in parts of the Southern Mahratta districts.

The recent rain in the North-Western Provinces and Oudh and in the Punjab has been beneficial to the crops, and agricultural prospects are generally very favourable. In the *Berars rabi* prospects are good, and standing crops are progressing in the Nizam's territories. In the Central Provinces, the Central India and Rajpootana States, standing crops promise well.

The rain which fell in Bengal during the past week has improved the *rabi* crops generally, but has injured the prospects of the poppy crop in Shahabad and Sarun. *Amun* paddy has been nearly harvested, and the cultivation of early paddy has commenced in places. Gathering of the early *rabi* crops continues. Seasonable weather prevails in Assam, and lands are being prepared for the *amun* crop. Harvest operations have been nearly completed in British Burmah.

Cholera is abating in Coimbatore and Tanjore, and is prevalent in Prome and a part of the Amherst district of British Burmah. In other provinces, the public health is generally good.

Prices are generally stationary.

Madras.—General prospect fair, except in parts of Bellary and Anantapore.

Bombay.—*Rabi* harvest commenced in parts of Ahmednuggur, Sholapore, Belgaum, and Kaladgi; standing crops slightly injured by mildew in several talukas of Nasik, and by frost and small insects in parts of Poona, and cotton and tobacco in parts of Hyderabad; by frost cotton blighted in parts of three talukas of Dharwar and one of Belgaum; scarcity of fodder and drinking water continues in parts of the Southern Mahratta Country districts; cholera in parts of five districts; small-pox and cattle-disease in parts of ten, and fever in parts of fourteen districts.

Bengal.—Rain fell in many districts benefiting *rabi* crops generally; in some places it has to a certain extent injured *rahur*, linseed, and poppy; harvesting of *amun* paddy is nearly finished; cultivation for early paddy has commenced in some places; gathering of early *rabi* crops is going on; prices of food grains almost stationary; cases of small-pox and cholera are still reported, but on the whole the general health is good.

N. W. P. and Oudh.—Rain fell in all districts during the week, doing much good; there was also some hail in places, but little injury was done; prospects continue favourable; supplies are sufficient and prices rule easy; the condition of men and cattle is favourable.

Punjab.—Rain throughout the province; health and crop prospects good; prices almost stationary.

Central Provinces.—The weather has become cooler during last three days; prospects continue favourable; health generally good; prices steady.

British Burmah.—Cholera prevalent in Prome town and in part of Amherst district, sporadic in five other districts; small-pox prevalent in towns of Thayetmye and Hensada, sporadic in two other districts, otherwise public health good; cattle generally healthy; harvest operations nearly over.

Assam.—Weather seasonable; prospects of winter crops good; public health good.

Mysore and Coorg.—Crops in Bangalore and Toomkur districts in fair condition, but withering in parts of Kolar; prospects depend upon early

rains; general prices show a tendency to rise; health generally good.

Berar and Hyderabad.—Weather cool and clear; cotton-picking and *jowari*-threshing continue; *rabi* plants progressing favourably; health generally good.

Central India States.—Wheat, gram, and opium crops are thriving; weather getting warmer; health good.

Rajpootana.—Weather has been changeable, but is now seasonable; health and prospects good.

Editorial Notes.

SOME time back we had announced that an Agricultural Exhibition will be held at Doomraon on the 17th, and four following days of the current month and from the prospectus published in the *Statesman* it appears to be a great success. It is a truism that the prosperity of a country depends on the development of its material resources; but while it is unfortunately the case that the whole Empire in India is living upon the soil, and that there is no satisfactory indication that India is increasing in material prosperity in respect of its handicrafts and manufactures, the circumstances of agriculture are in general so backward, that it has been calculated by no less an authority than Dr. Hunter, that forty millions of the population of India pass their days in chronic starvation. Many parts of the country are notoriously over-populated, and where this is not the case, the system of agriculture is of too primitive an order for the soil to return its proper yield. The establishment by the Government of experimental farms in various parts of the country must be applauded, and equally the agricultural scholarships founded by Sir Ashley Eden; but the method to be kept in view is that which can be effected by the people themselves, and suited to their simple circumstances. It is a move in the right path when, under the intelligent direction of the Hon'ble Jai Parkash Lal, and a committee of the European officials of the district, the Maharaja of Doomraon has determined upon holding an Agricultural Exhibition. It is intended to exhibit every agricultural appliance in use in the Doomraon estates, every description of cereal and crop grown, and to illustrate the methods of cultivation, together with the domestic utensils, clothing, and home manufactures of the people. We shall thus get a view of the actual agricultural condition of the district. Agricultural improvements and appliances have been too much theorised upon; and the *desideratum* is every fact in connection with the cultivation of the soil, and the various indoor employments by which the cultivator enhances his means and comforts. It should be possible, with the knowledge acquired, to indicate to the peasant neglected sources of substantial profit, while it is of primary importance that those charged with the management of the Exhibition, should secure a chemical analysis of the soils on which the various descriptions of crops are grown. The cultivator has no idea of manuring, and it should be possible to ascertain what artificial compositions may best replenish the exhausted soil, without prejudice to caste feeling in this respect. We suspect that Mr. Nolan has had something to do with this Exhibition, and that we owe it to him that we are to have a great agricultural show, instead of another race meeting.

.

THE Honorary Secretary, Agri-Horticultural Society's Gardens, Madras, lately wrote to the President of the Municipal

Commission, Madras, "requiring some small casuarina poles to repair damages done to trellis work, &c., by the cyclone, the Superintendent of the Gardens sent as usual to the casuarina plantations outside the town for what he required. Three cart-loads of poles, some very small, worth say Rs. 5 per cart load, were accordingly sent in and charged at the toll gate, Rs. 1-4, for each cart, in addition to the customary toll. If this charge be not a mistake, it appears to me to be most unreasonable. I understand it is the same rate as that charged for teak-wood beams, worth perhaps Rs. 100 per cart load, and which may last and be useful for a century, while such casuarina poles as we require for garden work last only a year or two at most. As we now require a further supply of thin poles for temporary barriers at the flower show, fencing, &c., I shall be much obliged for early information as to whether so heavy a tax as 25 per cent thereon is to be levied, to enable me to limit our requirements accordingly." The President in reply said, "that the rate of Rs. 2-8 sanctioned by Government under Section 341, Act I of 1884, is a rate per ton, and is not *ad valorem*."

**

THE irrigation returns of the North-West Provinces canals for 1883-84 show that the irrigation for the autumn crop exceeded that of the previous year by 65,000 acres, and for the *rabi* by almost the same acreage. The great demand on the canals was caused by the absence of winter rains, and a large area under inferior crops was irrigated. Even allowing this, the area of wheat irrigated in the year under review, compared with that of the previous year, was over 100,000 acres in excess. By reason of a large quantity of sugar having been left in the market, the unsold portion of 1882-83, less of the cane was sown. The returns of the working of the canals show a good profit, varying from 4.45 per cent on the Lower Ganges to 27.96 in the Eastern Jumna. The Agra canal succeeded, owing to the extent of its distributaries, in showing a profit of over 6 per cent. The total profit on all canals, on the capital outlay, amounted to 7.33 per cent. The last year, however, was an exceptional one, and it is not expected that a like satisfactory balance-sheet will be shown for the present year. The autumn and winter rains were both opportune and copious, and consequently, the demand for canal water has diminished.

**

MESSRS. WM. JAS. & HY. THOMPSON in their fortnightly circular say that upwards of 48,000 packages of Tea have been brought to the hammer during the fortnight, 1,700 of these being Ceylon Tea and 2,100 packages second hand and reprinted parcels. Considering the weight of supply and the unattractive quality of so large a portion of it, the market has shown strength and a healthier tone than in December, with more general buying by the trade; and where the teas offered have had special quality, the competition has been really good. The proportion of fine Tea coming forward, however, is small, and the improved prices paid for choice qualities—in some cases showing 2d. to 4d. advance—are fully justified. More attention is being paid to good Pekoes between 1s. 3d. and 1s. 6d., which have been so depressed, and nearly 1d. recovery is quotable. There is also more enquiry for good liquoring Pekoe Souchongs and Brokenes between 10d. and 1s. at rather better prices than have lately been paid. In common qualities, which unfortunately form the larger part of recent supplies, the movement has been adverse to sellers, demand having been insufficient to keep prices steady; lowly kinds, after selling lower than hitherto, close firm with more enquiry, but Fannings and Brokenes show ½d. to 1d. decline from December rates upon grades between 8d. and 9d. and fully 1d. on broken Pekoes between 10d. and 1s. 2d. per lb. The estimate issued by the Association in Calcutta on the 5th instant is 60 million lbs., available for shipment to London. Upon this basis the receipts from all ports will be about 65 million lbs., against 63 million lbs. last year, while at the present rate of consumption the deliveries during the same period will be 67 million lbs., as compared with 60½ millions last season. These figures have begun to attract attention, but have not yet been appreciated by the dealers sufficiently to influence their operations. The shipments to December 31 were 51½ millions against 47½ millions last year.

ONE of the difficulties about ensilage has hitherto been the uncertainty whether the silage would turn out sweet or sour. But Mr. James Howard, M.P., by filling a 20ft. high brickwalled silo with mown clover, trampling it on the pile, and adding successive quantities of clover during two or three days, found that the mass heated sufficiently to destroy the bacteria which would have induced sour fermentation. Then by covering the whole with an air-tight roof, sealed by dipping into a water-joint or trough round the eaves, and without any weighting or pressure at all, he kept the silage sweet, good and fragrant, but slightly alcoholic in odour. By these experiments of Mr. Fry and Mr. Howard, we have now a silo under control, and not of a cost that will preclude its wide adoption.

**

WHILE on this subject, we might as well add that something new on the ensilage system has just been propounded by Mr. C. J. Johnson, of Darlington, who has proved the possibility of building any green food into open stacks, and by the application of screw pressure of converting it into excellent silage with only a very slight quantity of waste at the outsides of the stacks. It appears that on the hillsides of Kinross-shire, Mr. Parry Russell, by adopting Mr. Johnson's system, has made a 90-ton stack from *Juncus articulatus* which would otherwise have been entirely wasted, and the stack is so good that it has to be fenced off to keep the stock on the moor from it. If the expense of making silos can be saved, the ensilage system is likely to go ahead with still more rapidity than at present.

**

A CORRESPONDENT of a home paper writes to say that he has been an eye-witness to repeated experiments made by the late Mr. Andrew Croase, in his laboratory at Fyne Court, in submitting milk to electric action, by which it was kept sweet for weeks together. The process is as follows:—"Two cylinders of sheet zinc and zinc iron are severally placed in two porous earthenware tubes, open at the top, closed at the bottom, the same being filled with water and connected at the top by a copper riband. The earthenware vessels are placed in the fluid (milk or other), and the electrical action immediately commences, and the fluid becomes antiseptic in a few hours. Milk has been kept sweet for three weeks by this process in the middle of summer."

**

A HOME contemporary in an admirable review of home and foreign agriculture during the past year says, that the year just closed will long be memorable in the annals of agriculture as that in which excellent wheat in large quantities was sold at less than 30s. a quarter, a price unprecedented in lowness since the value of money has been anything like its present standard. During the last hundred years the low weekly average of 30s. 6d. per quarter, recorded for the week ended November 29, has never been approached; the lowest average for any previous weeks in the century having been 35s. 6d., the price for the week ending Oct. 11, 1851. The year will also be noted in connection with one of the severest and most prolonged droughts on record. It has been a year, too, of alternate hopes and fears, culminating in general disappointment. When it opened, wheat and other autumn-sown crops were in a flourishing condition, after an extremely dry and mild winter. A few frosts in February gave a salutary check to upward growth, and a dry and sunny March further ensured the tillering and healthy root-growth of the young wheats. At the end of the month there was an abundant rainfall, which was very welcome in the light-land districts. Unfortunately, it was followed by a prolonged visitation of bitterly cold east and north-east winds with a few night frosts which gave a sickly hue to the wheats on the days. The check to vigorous vegetation then given was in all probability the cause of such deficiency as was noticed in the wheat ears, subsequently, as the blooming time was particularly favourable, and there was nothing to account for the mischief in the climatic influences of the summer months. Thus it happened that wheat, instead of the great crop at one time expected, turned out to be only about an average one. Spring corn, on the other hand, improved so greatly as harvest approached that it yielded much better than could have been expected

when, after being put in rather badly, it was nearly parched up by the drought of the latter part of the spring and the early portion of the summer. The hay crop was one of the lightest ever grown; and the root crops did not yield an average weight, though they improved immensely towards the end of the season. Fortunately, the autumn was mild as well as dry, so that stock were kept out in the fields and pastures much later than usual, and the stores of the winter keep were thus economised to an extent nearly or quite equivalent to their deficiency. On the whole, farmers would have done pretty well if the prices of corn and meat had been equal to those of last year; but all kinds of grain dropped in price, and meat sold so badly that graziers who bought lean stock in the spring at the high prices then prevailing, had little if any margin to pay for the summer's keep when they sold the animals, fat in the autumn. The crop in mutton was much greater than that in beef; and, as wool continued to sell badly, sheep graziers suffered more severely than feeders of cattle. As for many years past, dairy farmers did better than any other class of agriculturists during the year 1884; for the abundance of feed during the genial autumn did much to compensate them for the effects of the summer's drought. It is to be feared that in the vast majority of farm accounts for the past year, the balance will be on the wrong side.

.

THE attention of the Government of Madras has recently been directed, by Professor W. T. Thiselton Dyer, of the Royal Gardens, Kew, through the Secretary of State for India, to the following extract from the *Journal of the Chemical Society* for November 1881:—"Butter Beans," a new variety of fatty seeds, by F. V. Höhnel and J. Wolfraner (*Dingl. polyt. J.* 252,333-337). During the last few months, fatty seeds of remarkable size have been brought into commerce by way of Marseilles and Trieste, consisting of the split embryo of endospermless seeds which belong to the *Vateria Indica*, a tree growing in India (especially Malabar), whence large quantities of vegetable fat (Malabar tallow) have been recently imported into Europe. The seeds are brought into the market in a decayed condition, the fruits being gathered triennially, and not as they fall from the trees. The seeds have an aromatic and bitter taste and a faint aromatic odour. Examined under the microscope, they appear to be made up of thin isodiametric parenchyma cells, the contents of which are composed of three ingredients:—(1) yellow hyaline or fine grained masses of albuminous bodies (protoplasm), insoluble in boiling alcohol; (2) fatty substances, which are colorless, hyaloid, and crystalline, at places forming masses which, in consequence of the decay of the seeds, are quite separate from the yellow albumen; (3) numerous starch granules (to the extent of from 15-20 per cent). The seeds of the *Vateria Indica*, when dried in the air, contain 49-51 per cent of a greenish yellow solid fat characterised by its agreeable, slightly balsamic odour. The fat resembles mutton tallow in hardness and viscosity, has a sp. gr. of 0.915 at 15° and melts at 42°. It consists of 81 per cent neutral fatty acid glycerides and triolein, and 19 per cent free fatty acids. The fatty acids separate from the products of saponification, melt at 56.6°, solidify at 54.8°, and represent a mixture of oleic acid, and solid fatty acids melting at 63.8°, and constituting 60 per cent of the total weight of vegetable fat.

.

WE have been favoured with a copy of the Report of the Madras Agricultural College for the fifteen months ending the 30th June 1884, an arrangement adopted in compliance with instructions conveyed in the proceedings of the Director of Public Instruction of the 17th September last. The period under review embraces the 14th, 15th, and 16th sessions—two summer and one winter sessions. At the beginning of the period the names of 60 students were on the roll, and a fresh class was formed in October, which consisted of 34 students. At the end of the 14th session, seven students who had completed their course of training left the college. The number of students at the close of the period under review was 87—Europeans, Eurasians and native Christians, 8; Mahomedans, 12; Brahmans, 47; Sudras and others, 20. In addition to the students enumerated

above, 16 probationers of the Cattle-disease Inspector's Department and two or three schoolmasters attended lectures in the college. The seven students who completed their course of training at the end of the summer session, 1883, obtained certificates as follows:—6 first class, 1 second class. Of the students on the roll at the end of the last summer session, 1884, 15 have gained first-class certificates and 4 second-class. The report consists principally of tables showing the name, age, nationality or caste, position of parents, approximate area of land held in family, educational attainments in entering the college, and the number of marks gained by each student during the session. The average age of the students is about 22, but there is one—a Eurasian, of only 15½, and another—a native Christian of 28. The statement showing the amount of land held in the families to which the students belong is very satisfactory indeed. While there are only nine families that have no lands, the possessions of the others vary from 4 acres to 1,100 acres, and in one case to 1,600 acres. The educational attainments of the students before entering the College are not generally very high, but four have successfully passed the F. A. examination, and thirty-two the matriculation examination of some of the Indian Universities. There is one feature of the report which strikes us as being very useful, although not without precedent in the annals of educational records: we mean that portion of it which is occupied with examination papers. It acts as a land-mark for future students and a guide to them in their studies. If this practice were followed in connection with University examinations, it would save a great many disappointments and failures. During the year under review, some changes took place in the staff of the institution. On the death in August 1883 of Honorary Surgeon Hamilton, F.R.C.S., Lecturer on Chemistry, Surgeon-Major Rogers, M.B., F.R.C.S., was appointed Chemical Lecturer, which office he continued to hold till the middle of June when his lamented death occurred. The former gentleman had been connected with the college since its foundation in 1876. The chair of Chemistry is now vacant. Other changes also occurred by the separation of the College from the Farm when Mr. Robertson was placed in the graded list of the Educational Department from the 1st of April last, and Mr. Benson, having severed his connection with the College, took up the appointment of Agricultural Reporter and Superintendent of Government Farms. We are glad to observe that physical training is not neglected in the College, and that gymnastics form a regular course in the educational requirements of the institution. An important branch of work is the Veterinary Department under the able management of Mr. J. Mills. We are told that the students take great interest in the practical lectures at the Veterinary Hospital, where they have had the benefit of seeing about 100 cases during the session. This enabled them to apply their theoretical knowledge—the all-desirable end in the teaching of Veterinary surgery.

.

ABOUT a couple years ago a travelling agent from Arakan was touring through Bengal, for the purpose of gauging public opinion in regard to the introduction into the country of the indigenous earth oil. We believe his mission was not crowned with the success he anticipated, but he had our assurance that if a sufficient quantity of it could be raised, we had no doubt of the venture proving a remunerative one. Our predictions have not been doomed to disappointment. The report of the Borongo Company shows how successful it has been. It is the largest worker of the wells, employing steam machinery for sinking wells and pumping. The working staff consists of Englishmen, Canadians, Chinese, and Indian labourers. They have at present twenty-four wells, eight of which were sunk last year, the deepest of which is over 1,200 feet below the surface. Owing to want of sufficient pumping apparatus, only nine wells are regularly worked. Last year 234,000 gallons of crude oil were pumped, of which 65,450 were refined and the rest sold as they were. A great quantity of it finds a ready market in British Burmah alone, while Calcutta gets its complement, the refined oil, sold at 9s. per case, being cheaper than Devos's American oil which sells at 10s. 6d. per case. The price of the crude oil is valued from 1s. to 8s. per maund of 11 gallons. The Arakan Company also started

some works last year, and sank seven wells, the deepest of which was 400 feet. The five wells worked during that period yielded 107,800 gallons, which were all sold on the spot without being refined. Another and a third Company, known as the Petrolia Co., sank ten wells during the year, but no oil has yet been obtained. Natives have taken the hint from European enterprise, and have revived the industry which they carried on some years past. Although the machinery employed by them is rude and primitive, they have on the whole been very successful, and may be congratulated on their good fortune in having a good outturn for the small outlay. The entire quantity of oil raised in the district is given at 404,325 gallons. There are, however, some impediments in the way of a prosperous trade, such as the heavy cost of importing machinery, and the high rates of wages which obtain in the district, owing to its extreme unhealthiness. The difficulty of proper roads to the sea-ports is a great drawback in the expansion of the trade, but this, it is admitted, will not be permitted to remain long in the way of a healthy development of the industry.

.

On the 28th November last, Mr. A. T. Arundel, President of the Municipal Commission, Madras, wrote to the Chief Secretary to Government:—"The bursting of the Red Hills Lake has removed one of the greatest difficulties in the way of a portion of the scheme for increasing and purifying the water-supply referred to in my letter, No. 1101, dated 4th September 1884, Financial Department; I refer to the laying of the new pipes through the bund into deep water, and the building of a water-tower in the deepest part of the lake. The execution of these works with the lake full of water would have been exceedingly difficult and costly. The recent unfortunate disaster has laid almost bare the site of the proposed work, it is necessary to take immediate advantage of the present opportunity and to commence the work without delay. Apart from the debateable details of the scheme there is, I believe, no question as to particulars of the work to be done within the bed of the lake. Colonel Hasted, before he left Madras, went fully into and approved the scheme which Mr. Jones desires to adopt. I beg, therefore, that the Government will be pleased to approve of the immediate commencement of the work to which I have referred. The cost will approximately be Rs. 36,020, and can be met out of the grant of Rs. 75,000 which the Government were pleased to bestow for this purpose. Mr. Jones, a copy of whose letter I enclose, has already discussed the matter with Colonel Prendergast. The work now proposed would be carried out subject to Colonel Prendergast's approval, and I am sure the Municipality may rely on receiving his co-operation, and that of the Engineer in charge of the lake."

.

The following is from a note by the Chief Engineer for Irrigation:—"In paragraph 4 of Note printed with G. O. No. 1174, Public Works Department, 5th April 1877, the Chief Engineer for Irrigation detailed the improvements considered necessary to remedy the effective arrangements under which the town of Madras is supplied with water from the Red Hills tank: he considered that a better off-take should be selected and proper means for drawing off the water from the tank provided, and that the water should be raised to at least the level of the high ground near Mr. Ritchie's house, properly filtered, and conveyed by pipes instead of by an open channel to Madras. The Government, however, in their order considered that much investigation was necessary before it could be decided whether it would be preferable to let the water from the tank gravitate to filters near the town, the filtered water being afterwards pumped to the required level, or whether it should be pumped from the tank into filters placed at a convenient level near the tank. The subject has been duly considered and investigated by the Municipal Engineer, and approximate estimates have been framed by him for both schemes. I have examined the plans relating to both, and have no hesitation whatever in stating that it is in every respect better to raise the water near the tank, and convey it in pipes to Madras, than to convey it in an open channel to Madras, and

there raise it. I consider an open channel for the conveyance of drinking water to be objectionable, and were it not so, the level at which the water would reach Madras to be filtered would be so low that there would be great difficulty in arranging the filters properly. There is no doubt that water should be drawn from the tank at a much lower level than it is at present, as in the famine year, irrigation had to be stopped, and then water had to be pumped up to the level of the off-take. The proper method of drawing off water is through a water-tower so constructed that as the water-level falls in the tank, the surface water can be drawn till the tank is nearly empty. The whole contents of the tank will thus be available for the town supply instead of only a portion, as at present. I have lately examined the plans under preparation by the Municipal Engineer and approve of the general design of the water-tower, and would strongly urge that its immediate construction should be sanctioned while the tank is nearly empty; if the work is delayed until the tank fills again, there will be great difficulty in constructing the tower, and the cost will be very great. The tower should be built of the best materials, good brick and hydraulic mortar, and two iron pipes for drawing off the water should be laid in the masonry tunnel through the bank in the first instance, as any failure of one pipe would otherwise cause a stoppage of the water-supply." On the 20th December an order was issued by Government to the effect that the immediate construction of the tower was sanctioned, the cost being met in the manner proposed by the President.

.

The recent visit of the Chief Commissioner of the Central Provinces to the Umaria coal-fields has been productive of much good. He has seen with his own eyes the capabilities of the coal-field, and the account to which it could be turned. The coal is not only handy, but of excellent quality. The railway to Kutni is being pushed on rapidly, and trains will be running by the next cold season. Coal should be landed at Kutni for about Rs. 4 per ton. Thus in the midst of two important railway systems where fine iron ore may be found in abundance, as well as limestone and manganese, the facilities for the manufacture of pig-iron are ample. If we are not mistaken, the Chief Commissioner has authorized to make some experiments in smelting which, in due course of time, will be made public. Here a great deal might be effected by private capitalists who could conduct the operations on a large scale.

.

The results of the wine harvest of 1884 in Europe show that Germany has had the best yield, for more has been obtained there than in 1883, and the wine is also better in quality. All the other wine-growing countries have to register a falling off as compared with the previous year, both as regards quantity and quality. In Germany more than half a crop has been obtained, the quality being described as pretty fair. France has harvested less wine than in 1883, and its quality has, besides, not reached that of 1883. Spain and Portugal are in a similar position to France, for their 1884 wine harvest is less remunerative than in the preceding year, there being also a deterioration in quality. In Italy the yield is much less than in 1883, which is more particularly the case in North and Central Italy. The South of Italy has a somewhat better harvest, but the result on the whole is not so favourable as in the previous year. The quality of the 1884 wines of Italy is considered satisfactory; it varies very much, however, and is below that of the wines of 1883. In Switzerland very little wine has been harvested, and that little is only of medium quality. The deficiency, as compared with 1883, is considerable in every respect. In Greece, likewise, a falling off is recorded in comparison with the preceding year. In Austria about three-fifths of last year's yield of wine has been harvested, the quality being also, on the whole, worse than in 1883.

.

Mr. B. D. PLUMMER, reported to the Directors of the Mysore Gold Mining Company, on "Mining Operations:—" "We have in hand the following works:—Sinking Taylor's shaft under the 173, the lode is mixed with

branches of quartz, trap-rock, and arsenical pyrites, and is worth 1 oz. of gold per ton. The south end at the bottom of the mine is very hard to cut, and little progress is made. It is, however, a good strong lode, and will yield 10 tons of ore per fathom, the assay value of which is 3 ozs. 0 dwts. 10½ grs. per ton. The north end at the bottom of the mine is, if anything, tighter than the south end. It is a fine lode, 3 ft. 6 in. wide, worth 10 tons of picked ore per fathom, the assay value is 3 ozs. 0 dwts. 10½ grs. per ton. The winze in the bottom of the 173, on the west lode, continues tight to cut. The 173 north end on the west lode is at present suspended on account of the men quitting the company's employ. The air in this end is so bad, however, I do not now propose resuming operations until some better mode of ventilation is provided. There is nothing new to report from the 173 north end on the east lode. No. 1, 2, and 3 rises over the 173 are in good kindly looking quartz, the assay value is 11 dwts. per ton. The 135 north end has been in a good big quartz lode towards the bottom of the end, but just now it is almost entirely in old workings. We are getting on very well with the cross cut at the 173. We have, however, a good deal of timber to put in before we can start the proposed work on the lode. The machinery is in good working order."

.

A HOME contemporary, writing on the subject of the growth and exportation of Indian wheat, says that it is, from the economical point of view, a real Asian mystery. Most of those who followed the evidence given last summer before Lord Kimberley's Indian Railway Committee must have been astonished at the magnificence of the visions of the future, which were described by the enthusiastic supporters of the rapid extension of locomotive facilities for the transit of grain. He* who for the first time is told that it is feasible, under certain conditions, for India to supply with wheat, not only the whole of the United Kingdom, but also the cities on the eastern coast of the United States, at lower rates than those at which it can be sent from Chicago, is inclined to regard the statement as one of the "fairy tales of science." And it must be admitted that certain unquestionable facts would seem, on the face of them, utterly to demolish the optimistic theories which were laid before the Railway Committee. The assembled shareholders of the East Indian Railway, for example, were told the other day that the recent falling off in the revenue of the Company was due to the fact that of late they had been carrying no corn to Calcutta for export to Europe—the result of the exceptional cheapness this year of English-ground corn. But now, again, we are informed by the India Office that the area of land in the North-West Provinces and Oudh alone under pure wheat cultivation this year is more than half-a-million acres over the normal amount, and 337,000 acres more than last year. It is not, however, impossible to reconcile the whole of these apparently contradictory statements. At the very moment when wheat is so dear at Calcutta, at Bom bay, and at Kurrachee, that it would not be worth while to ship it, even if no freight were chargeable, to the Thames or the Mersey, there are practically unlimited lands within four hundred miles of these ports, where such wheat as is grown has to be completely wasted, simply because there are no railways by which it can be conveyed to the great trunk lines. It may, therefore, fairly be assumed that the Indian cultivators who are increasing the area of wheat-growing land are doing so in the expectation that the rapid extension of feeding railway lines will soon enable them to place a commodity, at present practically worthless, in the markets where it will command a remunerative price, even when placed in competition with European and American grown corn.

.

A CORRESPONDENT writing to a Ceylon paper says:—Within the range of the limestone deposits, indeed, plants either of tea, cinchona, coffee or vanilla enjoy an immunity, and this fact attracting attention led to the employment of crushed or rather pulverized limestone, as a manure. One garden that had suffered so severely as to be on the point of being thrown up, was thoroughly renovated by the application of two pounds placed round the base of the stem of each plant. The cost of application being for an acre of tea, 2,722 plants, at a task of 500 for 3 annas, a little over a rupee per acre. If there

is no limestone in the vicinity, the cost of getting it from Bengal would not amount to so much as the indulgence in those highly priced artificial manures at present in vogue. Lime is the most powerful renovator known (renovation must not be confounded with stimulation whose effects are transient.) Lime contains all the elements of strength-giving vitality, and, plants, so strengthened, will be as well able to encounter disease as a strong healthy man does. The puny effects from renovating pits filled with cowdung and weeds avail little, and cost three times as much as a seer of limestone would. It is unreasonable to expect that our plants of tea, coffee, cinchona, cinnamon, or other spices can go on standing the exacting demand constantly made on their leaves, berries, and bark without some corresponding nourishment as compensation, and though disease must be endured, our plantations must be strengthened to fight it, even, where it can be afforded, at the expense of abstaining for one whole year from growing a crop, after liming.

.

THE following summary of the report of settlement operations for 1883-84 in connection with the cadastral survey of Kamrup will be found interesting:—The work devolving on the Settlement Department was the preparation of the new cadastral field-register in the place of the old mauzadari *dag chitha*. The plan followed was to get the new field-register (the *khasra* or cadastral *dag chitha*) written up on the field simultaneously and independently by the cadastral amin and the mandal or deputy mandal who accompanied him. On the area columns of the field-register (which were left blank at the time of writing) being filled up by the survey office, the settlement office proceeded to compile the *jamabandi* from it, and where discrepancies of an important character were found to exist between the new cadastral *jamabandi* and the mauzadar's *jamabandi* of the preceding year, spare amins were deputed with settlement munshis to enquire into and reconcile them. The area covered by the cadastral field-to-field survey was 22416 square miles, comprising nine mauzas in the centre of the Kamrup district north of the Brahmaputra. Besides this, 298 square miles were covered by the preliminary village-boundary survey, in anticipation of the field survey of 1884-85. The cost of the complete survey of the nine mauzas was Rs. 74,772, or Rs. 328 per square mile; that of the additional 298 square miles of boundary work was Rs. 19,268, or Rs. 328 per square mile; that of the additional 298 miles of boundary work was Rs. 19,268, or Rs. 64-10 per square mile. The survey ought to be able to work down to lower rates than these in 1884-85, but for a first season's operations they are not excessively high. The settlement expenses are shown as Rs. 17,128, but this figure does not agree with the Comptroller's calculations; the difference is understood to be due mainly to the omission of the Extra-Assistant Commissioner's pay and travelling allowance from the settlement of accounts. The results attained within the period under review were the completion of the rough field-registers for the nine mauzas, and the preparation of corrected field-registers (after the enquiries by the amins and munshis mentioned above) for a small number of villages. The process of correction is still going on, and the new cadastral field-registers will not be ready for use until 1885-86. This is slower progress than was hoped for, but the settlement (and, to a less extent, the survey also) had to contend with serious difficulties in the ignorance and apathy of the ryots, and the difficulty of procuring men who could be trusted to write the field-registers correctly, or to check them when written. The lesson learned from the season's work is the importance of getting a correct field-register in the first instance. No degree of apparently rapid progress can compensate the labour and delay subsequently entailed by the necessity of going over the same ground again, and correcting the mistakes of haste or carelessness. Attention must be paid to this point during the present season, and it is hoped that the cadastral field-registers of the mauzas surveyed in 1884-85 will be found to contain a smaller proportion of error than those of the first season of survey and settlement work, when everything was new, and the staff employed in the field were imperfectly acquainted with their duties.

EXPERIMENTAL STATIONS.

As the Local Government is about to organise an Agricultural Department in Bengal, it will not perhaps be out of place to give here a short sketch of the origin, scope and plan of the Rothamsted Experimental Station, the best of its kind in England, and, if not the best, at least one of the best in the whole world.

Mr. (now Sir) J. B. Lawes is the founder of this experimental station. He commenced experiments with different manuring substances, first with plants in pots, and afterwards in the field, soon after 1834. His experiments at first were not very systematic. In 1843 more systematic field experiments were commenced, a barn was converted into a laboratory. The foundation of the station may be said to date from that time (1843). The Rothamsted station has up to the present time been entirely disconnected with any external organisation, and been maintained entirely by Sir J. B. Lawes. He has further set apart a sum of £100,000, and certain areas of land, for the continuance of the investigations after his death.

In 1854-55 a new laboratory was built by public subscription of agriculturists and presented to Sir J. B. Lawes in July 1855. From this date, the old barn-laboratory was abandoned. The number of assistants and other helps was increased from time to time.

At first only one laboratory-man was employed, but very soon a chemical assistant was necessary, and next a computer and a record-keeper. During the last 25 years the staff has consisted of one, or two, sometimes three chemists; two or three general assistants. One of these is usually employed in routine chemical work, but sometimes in more general work. The chief occupation of the general assistants is to superintend the field experiments—that is, the making of the manures, the measurement of the plots, the application of the manures, and the harvesting of the crops; also the taking of samples, the preparation of them for preservation and analysis and the determinations of dry matter, ash, &c. These assistants also conduct experiments made with farm animals. There are now over 30,000 bottles of sample of experimentally grown vegetable produce, of animal products, of ashes, or of soils, stored in the laboratory. A botanical assistant, with 5 or 6 boys, is also occasionally employed to undertake the botanical work.

Two or three computers and record-keepers have been occupied in calculating and tabulating the laboratory and field results. One or two laboratory-men are employed.

Besides the permanent laboratory staff, chemical assistance is frequently engaged in London or elsewhere, and in this way for some years past, Mr. R. Richter, of Berlin, has been almost constantly occupied with analytical work sent from Rothamsted. The investigations carried on in the Rothamsted Experimental Station may be classified under two heads:—

(I.) Field experiments; experiments on vegetation, including investigation of soils, rainfall and drainage; botanical and physiological matters.

(II.) Experiments on animals; with supplementary investigations on the application of town sewage to different crops, and especially to grass.

SILAGE IN INDIA.

We have no such thing as pasture lands properly so-called in Bengal, neither is the peasantry in Bengal sufficiently informed of their usefulness. They will perhaps be surprised to learn that in England pasture lands fetch higher rent than arable—that while the average rent for arable land is Rs. 28 to 30 per acre, that for pasture is Rs. 35 to 40. But they will cease to wonder at it, if they are told that British farmers manure and look after their pasture lands with as much skill and care as their arable lands, and as a remuneration for the skill, care, and capital bestowed on them, they get more out of their pasture than arable lands. The pasture lands are partly grazed in summer by stock-cattle,

sheep, horses, &c., and partly cut for hay, to supply fodder for stock in winter. The health of farm animals in winter is mainly dependent on the making of good hay in summer. It must here be clearly understood that hay is not mere dried up grass, as is understood by some in this country. It is grass cut in June and July when it is about to bloom, carefully cut, turned, and dried in the field, and ultimately carted, stacked, and thatched. Dry sunny weather is absolutely necessary for making good hay. The common saying "make hay while the sun shines" is nothing but the crystallized opinion of ages of British farmers on sunshine as an essential factor in the process of hay-making. But unfortunately for the British farmers, for the last few consecutive years, sunshine and good weather, during the time of hay-making, had been more an exception than a rule. To be independent of the sun in procuring winter fodder for stock has, therefore, lately been the aim of all intelligent British farmers. They are trying to introduce in their country the system of *ensilage* or *silage* making, long known and practised on the continent and in America. The system consists in making a reservoir called *silo*, in filling it with newly cut grass or any other green fodder crop carted directly from the field, and, ultimately, in covering it up in air-tight manner and having weights placed at the top to press the whole mass down. The grass is taken out of the silo after three months or any longer period, if necessary, and given to farm animals without any injury. While in the silo, the mass undergoes a certain amount of fermentation and other chemical changes, which render it into what is called *silage*. Whether silage is equal to hay in feeding property, or whether chemical changes and fermentation converting the green mass into silage, improve or deteriorate the feeding properties of the green fodder, are questions to be dealt with later on. For our present purpose, it is sufficient to state that cattle and horses take readily to silage; while sheep, indifferent to it at first, gradually get used to it, and seem to like it at the end. In most of the experiments where silage has been substituted for hay, and used as such, the results have been satisfactory.

It is high time for India, or better if we limit our area of observation and say Bengal, to benefit itself with the experience bought by the French, German, Americans and English, at the sacrifice of a large amount of money and a great amount of trouble. True it is that the condition of Bengal is very different from any of the above countries, but can we not adopt the system to altered conditions and circumstances? Our cattle suffer most for want of fodder in summer and during the rains. We have no proper pasture land, as we have said in the beginning, and the common or waste lands used as such generally get parched up under the burning rays of the summer sun. The cattle-men drive the herd to these waste lands to let them have their doubtful bite of dried-up grass. It is doubtful whether the cattle get sufficient to recoup their loss in going to and coming from the common lands which are usually situate at a considerable distance from the village. During the rains, some of the common lands get under water, while others remaining above water become difficult to reach, and even if reached would be quite insufficient for the number to be kept on them. During the rainy season there comes in another difficulty. The little paddy straw that the Bengal peasantry as a rule get after thrashing their corn, is used up by their stock during summer, and in covering their thatched houses, which is a periodical affair. So they have no dry fodder to fall back upon in the rainy season, as they have in summer.

It is of paramount importance, therefore, that we should lose no time in improving and extending, if need be, our pastures, and at the same time in making fodder reserves for use in summer and rains. The method of fodder reserve that seems to have a great future for India is the system of *ensilage*. Experiments on ensilage have already been set on foot by the Director of Agriculture in Bombay and in the Cawnpore Experimental Farm. The results of ensilage and experiments on feeding with silage, as given in the Bombay and Cawnpore Annual Reports for 1882-84 are very encouraging, though they are not yet sufficient in number and out-come of a long trial.

Miscellaneous Items.

SEVENTY bullocks are reported to have been frozen to death in one night recently in the Bolan Pass.

A Ceylon planter, who recently visited China and Japan, has brought back with him a collection of silkworm eggs, with a view to attempting sericulture in Ceylon. Former trials have shown the experiment to be attended with great difficulties.

THE Municipal Commissioners of Bangalore have rejected the scheme for diverting the Ulur Tank, on the ground, that whilst the civil population might or might not benefit by such diversion, the military would. Water is promised the non-military section from a certain source, but the getting of it is a doubtful matter, as the opinions of professional men differ on this point. The Board demand that the promised supply be first guaranteed them.

At a pleasant little evening party at Mr. Birdwood's, the Rev. Dr. Fairbank of Ahmednugger explained the structure and capabilities of his Eclectic Plough. From the account given, it appears to be a light but durable implement, well adapted to our soil. The plough is used first for loosening the soil, and then for turning it. Dr. Fairbank has used it on his own field which, we know, is the admiration of all who notice it, with success. We should like this model plough to be made known to our *kumbis*—it is cheap in itself, and needs only one pair of oxen to draw it.

SIR CHARLES TURNER, in the course of his address at the Veterinary College at Madras, the other day, said that there was no reason why Madras, Bombay, and Calcutta should be fed with indifferent mutton, and why the fleeces of the sheep should be inferior to those of Australia. If they carefully studied and realized the advantages of real veterinary knowledge, the food produce and the manufacture of articles would be considerably improved and add to the nation's wealth. The want of a knowledge of veterinary science allowed the destruction of large numbers of cattle.

THE experiments in growing and storing fodder in certain cantonments in the N.-W. Provinces, which owe so much of their success to General Sir Herbert Macpherson, are now about to receive the personal attention of the Commissary-General. Colonel Hunt, C.B., may be expected in Allahabad on or about the 21st, and is likely to be met there by Lieutenant-Colonel Burlton and Major W. G. Smith, Deputy Commissaries-General of the Lower and Central Circles, and Lieutenant-Colonel Badcock, C.B., from Rawul Pindie. The result of the conference should be a considerable extension of the useful operations already carried out.

A CONTEMPORARY hears by wire that the Bombay Exhibition will likely be postponed until the autumn of 1887. The Australian Colonies were asked whether December, 1886, or December, 1887, would be most suitable, and the replies generally favoured the latter year. America, it was also ascertained, could not exhibit in 1886, as she has an Exhibition of her own in London that year. Accordingly, a meeting of guarantors is shortly to be held to formally sanction the change of year. The Governor has promised to join the committee in London, and to come out to Bombay in a private capacity, so as to be present at the inaugural ceremony.

At Pondicherry, the prices of many of the principal necessary articles of food have been at almost famine rates ever since the floods of December last, owing to supplies from the interior being cut off; even now rice is selling at 1½ Pondicherry measures only per fanam (equal to Rs. 8-4 per bag), and coffee at 8 annas per pound; vegetables, usually very cheap and plentiful, have often been difficult to get at any price. The French Minister for the Colonies has, we understand, sanctioned as an *interim* measure, an extraordinary expenditure by the Pondicherry Government, on account of the late inundations, of two millions of francs (Rs. 9,70,870).

PLANTERS in Ceylon seem to be too numerous yet, notwithstanding the increasing acreage of tea. One or two of the best Ceylon men have turned their attention to Perak where good tin ore has been discovered. Another Ceylon planter is at Raugoon, and about to make some experiments with cocoa in that neighbourhood. In this connection we may mention that Mr. F. N. Cabanis, an American agriculturist, now in the service of the Government of British Burmah, has discovered indigenous grape in British Burmah, which in some respects resembles the native summer grape of Virginia. It grows very luxuriantly on either low, or rolling country, appears hardy, and is very prolific.

EIGHTY-THREE Javanese coolies, male and female, who had been engaged at Samarang by a planter for Deli arrived in Singapore recently by the British steamer *Normandy* from that port, and laid a complaint before the Netherlands Consul-General against their employer, and a Malay assistant for forcible ill-treatment on board by branding them on the arm. The case was referred by the Consul-General to the Master-Attendant, as the offence was committed on board a British ship, and a prosecution under the Penal Code was pending before the Singapore police court when the last mail left. The defence is that the marking was only done with cautery, and that no force was used, and no pain caused.

MR. M. A. LAWSON, Director, Government Cinchona plantation, &c., Nilgiris, reports that the total nett amount realized at the last three auction sales of cinchona bark was—28th July 1884—195 bales or 19,500lbs. of bark realised Rs. 20,444-12-2; 25th August, 112 bales or 11,200lbs. of bark realised Rs. 10,989-15-3; 17th November 1884—187 bales or 18,690lbs. of bark realised Rs. 16,453-13-7; Total, Rs. 47,886-9-8. He proposes to sell the under-mentioned number of bales and varieties of bark in February and March:—February 1885—20 bales Dodabetta Mossed Crown, 120 bales Dodabetta Renewed Crown, 60 bales Dodabetta Branch Crown. March—100 bales Dodabetta Natural Crown, 100 bales Dodabetta Mossed Crown. The Government has approved of these sales.

THE figures published in Messrs. Hart and Sibthorpe's report on the Indian Tea sales for the year 1884-85, regarding the business in London, ought to prove highly satisfactory to all owners of tea property in this country. We observe that the deliveries in January last were 6,390,000lbs., as against 5,610,000lbs. in the same month in 1884, whilst the stock in London on the 31st of January was 28,500,000lbs., as against 27,600,000lbs. The imports during January were only 7,770,000lbs., as compared with 9,080,000lbs. in January 1884, whilst the shipments from Calcutta to London in January were 5,254,000lbs., as compared with 5,287,000lbs. during the corresponding period of last year. This reduction in the imports, as well as the shipments from Calcutta, should certainly improve the strength of the London market, whilst the deliveries for the month are the largest on record.

THE causes of typhoid fever have still to be discovered and stated with authority; but both in England and on the continent, the prevalence of the disease is frequently associated with the existence of insanitary conditions, especially in connection with milk supply. Without in any way implying a connection between the two circumstances, we may point out that, in Lahore, where cases of typhoid occur periodically, our milk-supply is largely obtained from sources which can only be described as filthy in the extreme, and utterly disgraceful to the authorities whose duty it is to see to the sanitation of the place. Cow sheds and native livery stables, in the most disgusting state, are allowed to exist in the very centre of the civil station; and in the city and bazaars, affairs are still worse. Local self-government may be a valuable aid in the political education of the people, but when its direct results are disease and death, it is time to protest.

PEOPLE in Paris are just now anxiously discussing a question which may be of much greater importance to France than any of the others at present exciting interest; for it refers to the saving of one of her chief industries, namely, wine-growing. A medical man in the department of Maine et Loire is said to have at length discovered a means of overcoming the phylloxera by an easy and inexpensive treatment, the basis of which is an arsenical solution mixed with clanders. The limited experiments made with this preparation seems to have been attended with admirable results. A vineyard selected from a neighbourhood completely devastated by the phylloxera, and subjected to the new treatment, resisted the scourge in a most striking manner. Not only the foliage and stocks, but the roots remained perfectly intact, while the fruit is said to have been abundant and of excellent quality. Further experiments on a large scale are about to be made in the Meloc; and, the inventor having patented his remedy, the result obtained will receive all possible publicity.

THE importance of the irrigation and navigation works on the Godavari can best be estimated by perusing the figures published in the last report on the navigation of the canals for 1883-84. The mileage of the canals has been but slightly increased, that is, by only two miles, but as the number of cargo boats has decreased, the registered tonnage of them has lately increased, as has also the distance over which each ton was carried, but the value of the cargo has fallen considerably. Thus we find that the ton mileage amounted to 7,843,834 miles, which is estimated to have cost the owners of goods about two lakhs of rupees only, whereas by the ordinary means of carriage in the district, at the rate of 4½ annas per ton per mile, the cost would have been upwards of twelve lakhs. The value of the cargo conveyed is estimated at upwards of 126 lakhs, whilst the charge for navigation was only Rs. 63,414, or about 5 per cent. The return of the capital expended for the year is estimated at only 12-7 per cent, which does not seem a very large result for so much business.

THE *Pioneer* says:—"The further postponement of the Bombay International Exhibition we have regarded all along as, if not inevitable, at any rate advisable. An Indian and Colonial Exhibition at South Kensington, an American Exhibition at Battersea, and an International Exhibition at Bombay—all within six months of each other—could not have failed to clash seriously. As it is, quite apart from the serious loss that the Bombay Exhibition would have suffered in competition with the English undertaking, the authorities of South Kensington will no doubt have quite enough to do with America, close at hand, without being further handicapped by the rivalry of fellow-countrymen in India. A second postponement is no doubt a double evil; but the suicidal competition originally contemplated would have been worse. The abandonment of the Australian Jubilee Exhibition for 1887 clears the way, and the liberal promises of assistance from London render the probabilities of genuine success much greater for an Exhibition at Bombay in that year than they would have been at the earlier date. In deciding to give due weight to the simultaneous wishes of London, Australia, and America, the organisers of the Bombay Exhibition will have taken the only wise course open to them."

Selections.

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The Ordinary Annual General Meeting was held on Wednesday, the 28th January 1885

W. H. Cogswell, Esq., President, in the Chair.

COMMUNICATIONS.

From A. Mosley, Esq., Gibraltar, forwarding a small packet of Capsicum seeds and promising a further supply. Mr. Mosley mentions he would have been able to obtain all he wanted in the autumn, but the cholera scare prevented communication with the main land.

From J. A. Despeisse, Esq., of the Royal Society of Arts and Sciences, Mauritius.

"Dear Mr. Blechynden,—Many thanks for the parcel of timber seeds you sent some months ago to the Royal Society of Arts and Sciences of Mauritius.

Mr. Danetz, the Secretary, asks me to enquire from you what would be desirable for you to get at Mauritius? I send you, on behalf of our Society, four copies of her transactions, and shall have the pleasure shortly to send you four copies more which are in the press. Copies of your Journal are much sought for by us." Mr. Despeisse goes on to remark on the low state of the sugar industry through the great abatement of prices, and that he is interested in introducing new industries to the Colony. He asks for seeds of Cluchona, Divi-Divi, Chaunugra, and such others as may prove useful, and hopes that the Hingle tobacco seed already received from this Society will prove a success, and enquires regarding Mango grafts, and Indian Silk worms."

From F. St. C. Grimwood, Esq., Lakhimpore, Assam, forwarding a further supply of Muga eggs, in response to the Society's application to him. The Society's thanks are due to Mr. Grimwood for the prompt and courteous manner he has met the several similar applications made to him by the Society.

From H. H. Risley, Esq., Officiating Under-Secretary to the Government of Bengal, forwarding printed report on the competition of machines in the extraction of fibres, and the Lieutenant-Governor's Resolution thereon (transferred to Journal.)

ORIGIN OF THE FAZLI MANGO.

An interesting communication from W. H. Irvine, Esq., of Bholahat, Maldah district, relates the origin of the well known Fazli Mango: "The name *Fazli* is a corruption of Phozir Bee, the name of the Mahomedan widow in whose *Buri*, of a few square feet, a mango seed thrown carelessly struck root and grew uncared for to a tree, till the flavor of its fruit gave a reputation to it which has made the poor widow's name known all over Bengal.

"The tree is supposed to be some 80 years old, but from the unceasing demands on it for grafts, it is quite a wreck.

"The Fazli Mango is esteemed above all others by natives, although by Europeans it is considered insipid and inferior to the luscious 'Gopal Bhog,' the Malda type of the still more delicious Bombay 'Mazagaon,' which general testimony goes to prove is its parent. Fazli mangoes are costly, and Rs. 50 per hundred is no uncommon price."

INTERCHANGES.

From Colonel Pollock, dated Pau, 24th December 1884:—

"I am in receipt of yours of the 7th July, which had been sent on to the Congo and returned to me here, where I am on sick leave, but return again next month. I am much obliged to you for the seeds sent to Captain Grant Elliott; will you kindly send the seeds, &c., I wrote for subsequently, to Vivi, Congo River, addressed to the Administrator General, International Association of Africa, care of Messrs. Hutton and Co., Liverpool? It would be better if they could be sent via Li-hou as a steamer leaves that port every month on the 6th for the Congo, but I do not think there is any direct communication between that port and Calcutta. It is the quickest route too, for the steamer from Lisbon takes but 24 days, whilst that from Liverpool takes six weeks.

I note your requirements, and I think I can meet them, not immediately perhaps but within six months, for all the best foliage plants are to be met with near the equatorial regions of the Congo. I have secured the Ice plant for you, and will return the Wardian case with it and other plants. Pray send us Tippiaree, Dhall, Indigo, Morunga or horse-radish tree, Brinjal, Custard-apple, Assam or Burmese Orange seeds. I shall be glad to see the plants you have so kindly sent and promised.

We also should be glad to get seeds of the Musk Melon, Cucumber, and other plants of a similar nature.

Can you also send us Coriander, Ginger, Ajowan, Hibiscus Esculentus, Phaseolus Lunatus, Channa or Cicer Arietinum, Rumex Vesicarius, Dolichos Lablab, Dioscorea rubella, Huldee, Cardamom, Kulee Seem, Kalee Tulsee, Kureela, Amaranthus Oleraceus, Sag, Pulwul, Bilimbi, Cashew Nut, Pummelo, Tamarind, seed of the plant that yields Gingelly oil, Paluk, Poppy, Kelemear, Fennel, &c., &c.?

The Congo has no delta and very little land excepting perhaps very far up, fit for rice growing. Mr. Johnston's knowledge of the Congo is very superficial, and his book not very reliable,—made to sell.

I know the species of paddy you mention very well. There was plenty of it in Burmah where I served for 13 years.

Our rains begin in December and end in June.

There are very few fruits. The Mango trees on the Niger bear a very fine fruit, better than any ungrafted ones I ever tasted

in India, and the curious part of it is that the trees give three crops a year. I myself saw many trees loaded with fruit not quite ripe, but in full bloom also. I took a lot of the stones to the Congo, but not one germinated.

The Association has been recognized as a Sovereign Power by the leading European Powers, particularly by Great Britain, Germany and America.

With many thanks to the Society for their kindness in forwarding the plants and seeds.

The Association will have a vessel at Zanzibar shortly. I have written to the President, to write to you if he thinks his letter can reach you in time to send the seeds and plants that way. The B. I. S. N. Company's steamers ply from Calcutta to Aden, thence to Zanzibar. If you don't hear from the President, it will be a sign that the plants could not reach Zanzibar in time to catch their vessel."

It was resolved that the seeds, &c., asked for by Colonel Pollock be forwarded to him at an early date in the manner suggested; and that Col. Pollock be asked to obtain grafts or seed of the Niger Mango for the Society.

The Council's Annual Report was then submitted, as follows:—

During the year 66 members were elected and rejoined, a slight increase over the previous year and over 1882, the numbers in both having been the same (62); the resignations were, however, slightly more, 28, against 23 in 1883; in 1882 and 1881 the resignations were 38 and 55 respectively. In June last the President prepared and issued a Special Circular to the Proprietors, Agents, Managers, &c., of Tea Gardens, Indigo, Jute, and Cotton Factories, and similar industries, pointing out the many advantages to be derived from becoming a subscriber to the Society which had done so much to benefit the country during the last 64 years and which, with their united assistance, could do so more extensively still in the future. The result of his representation was the acquisition of a certain number of additional members, and doubtless the repetition of such a special appeal periodically will have good effect; for as old residents retire from India, it is essential to attract the attention of those who fill their places to the good object of the Society, as well as to the direct benefits it confers on members. The number of names removed from the list for non-payment of subscriptions shows an increase of one over 1883, 26 against 25.

The number of deaths are the same as in the two previous years.*

Owing to long absence from the country 20 names have been removed from the list, an increase over the previous year (11.)

The number of members on the list (576) are classified as follows:—*Life Members*, 30, *Honorary Associate and Corresponding Members*, 21, and *Ordinary Members*, 525. Of this number 37 are absent from India, and 43 have been non-effective in 1884, thus reducing the number of effective members to 445; the same number as last year.

The Council cannot pass over Sir Lawrence Peel's death without an expression of the great respect and esteem in which he was held by the Society, of which he was an Honorary Member since 1856, and had ever been a warm friend. A notice regarding Sir Lawrence Peel's death which appeared in the *Proceedings*, is reproduced in the *Journal*.

Flower Show.—For a variety of reasons the Council thought it inexpedient to hold the Annual Flower Show; they, however, encouraged their Malis competing at a small Show that was held within the Calcutta International Exhibition, where they gained one or two prizes.

Garden.—The Garden Committee have more than once reported favourably on the appearance of the garden and the internal arrangements; they consider the order, condition, and good progress reflect credit on the management.

There is now a very large stock of plants in hand, including Mahogany, Mango, and other Fruit Grafts, Roses, Crotons and other ornamental plants, although the distributions have been very large, 8,381 ornamental plants having been taken by members and 5,107 by non-members, or 11,488.

Of Fruit grafts 2,316 have been distributed to members and 349 sold to non-members, or 2,665 grafts. In all 14,153 rooted plants, exclusive of cuttings, have been sent out from the garden, against some 12,000 last year. Seeds have also been distributed independent of the usual allowance. During the half-year 645 packets of Vegetables, Flower, Ornamental Shrubs and Trees, Economic Plants, Fodder Grasses, &c., have been distributed without charge.

By the kind permission of Mr. Cloete, Executive Engineer, Presidency Division, the Society has been permitted to collect seed from the trees on the Maldan. There is now a useful stock of seeds ready for distribution.

In addition to the sale of 266 baskets of flowers, applications from Hospitals and Charitable Institutions for flowers, have met with ready response.

RICHARD BLECHYNDEN, JUNIOR,
Deputy Secretary.

THE WHEAT CROP.

THE following wheat forecast for the ensuing season in the Central Provinces, dated the 27th ultimo, from Mr. J. B. Fuller, Director of Agriculture, Central Provinces, to the Secretary to the Chief Commissioner, has been forwarded to us for publication:—

Sir,—In continuation of my No. C 160 A, dated 17th January 1885, forwarding a copy of a telegram despatched to the Government of India on the prospect of the season's wheat crop, I have the honour to submit a more detailed account of the condition of the wheat crop up to the middle of the current month.

* Deaths.—Sir Lawrence Peel, J. S. Armstrong, Maharaja of Bettiah, Mrs. Munro, Pree Nath Sett, J. Rayson, D. Steel, and R. B. Yates.

2. As mentioned in my letter above quoted, the orders calling for the submission by district officers of a forecast on the 10th January did not formally cancel previous orders under which a forecast was due from them by the 15th January, and I expected that the forecasts for the 13 districts, from which none were received, dated January 10th, would arrive by January 15th. But up to January 20th forecasts were still outstanding for six districts, including the important ones of Nagpore, Raipore and Bilaspore, and I have been unable to include particulars for them in this return. Under the orders contained in Circular No. 39, dated 4th November 1884, the forecasts submitted in the middle of January were to be accompanied by reports from district councils, but these have been received from only the two districts of Seoni and Betul.

3. *Area*.—Statistics of the area under wheat have only been received from one district (Hoshungabad) and the Deputy Commissioner distrusts their accuracy. Until, indeed, the reform of the village record staff has been completed, no area statistics of any value can be expected from these provinces. General enquiries seem to show that there is a decrease in wheat area of larger amount than I anticipated in my first forecast, dated December 19th last, and judging from the reports now received, the area in the northern districts is less than the normal by from 15 to 25 per cent. The largest decrease is that reported from Wardha, which amounts to 32 per cent. A special report on the causes of this has been called for. From the districts of Chhatishgarh no reports have been received, but I do not think from what I have seen in the Raipore district that the decrease in area amounts to more than 15 per cent.

4. *Outturn*.—The late falls of rain have been of immense benefit. In the last week of December there was a fall ranging, roughly speaking, from two inches in the southern to half an inch in the northern districts. Since then more rain has fallen north of the provinces, where more was needed. The district estimates show in many cases a substantial increase over those received in December. In Sangor only a two-thirds crop is anticipated, and in Hoshungabad even less than this. But these estimates are probably rather under the mark, and speaking generally, an outturn may be anticipated of from 80 to 85 in 100 in the north of the provinces, and from 90 to 95 in the southern districts. Perhaps the best proof of the favourable character of present prospects is afforded by the fact that the monthly price currents which are received in my office from the towns of Jubbulpore, Hurdia, Nagpore, and Raipore show that the price of wheat is very considerably less than it was after last year's harvest. The figures are as below:—

	Price per maund of 80 seers.			
	May 1884.		Dec. 1884.	
	Rs.	A. P.	Rs.	A. P.
Jubbulpore ...	1	11 11	1	9 7
Hurdia ...	2	1 4	1	15 4
Nagpore ...	1	12 10	1	9 10
Raipore ...	1	5 5	1	1 8

The high prices of last year may no doubt be attributed to the activity of the export trade. But the export of wheat has by no means stopped during the past three months. From October 1st and December 31st, 1884, the wheat exports of these provinces amounted to 15½ lakhs maunds.

5. A copy of this letter has been sent direct to the Secretary to the Government of India in the Revenue and Agricultural Department, and to the Secretary of the Bombay Chamber of Commerce. It will be printed in the next issue of the local *Gazette*.—I have, &c.

J. B. FULLER,
Director of Agriculture.

WHEAT MEAL BREAD.

WHAT IS IT?

WHAT ARE THE ADVANTAGES OF EATING IT?

[By Lady John Manners.]

THIS question was asked frequently during the International Health Exhibition by those who visited the stall of the Bread Reform League. The same inquiries were put by many who attended the Exhibition of the League, held by kind permission of Mr. Humphreys, at his fine hall opposite Knightsbridge Barracks, in the last week of November.

I have been allowed by Miss Yates, honorary secretary of the League, to answer these questions from facts collected by her during a long series of years, and from other sources.

Wheat-meal bread contains all the nourishment of wheat; parts which are thrown away from white flour are kept in it. Granulated wheat-meal bread is especially valuable for children, for the poor who cannot afford much animal food. Many eminent physicians and chemists recommend its use to their rich patients, and it is a thousand times more valuable as a daily article of diet to the poor who cannot have the variety that those in affluence command in their fare. In white bread, as it is ordinarily sold, it is said the component parts necessary to form flesh and bone are not to be found. Professor Liebig tells us that whole-meal bread contains about 60 per cent more phosphatic salts than meat, and 200 per cent more than white bread. Phosphatic salts are essential to make bones and teeth. Whole-meal bread is certainly more satisfying than white bread; in fact, as a food, it somewhat resembles the oatmeal on which many of the finest and most athletic men in Scotland live principally, with the addition of milk. Miss Yates writes:—

"There are numerous examples of people being healthy and vigorous without ever touching meat, when their principal food is brown

bread. I have already mentioned the Arab fellahs, Turkish hamals, and Sicilian peasants whom I have seen myself personally. From friends I hear that the Hindoos of the North-Western Provinces can walk fifty or sixty miles a-day, with no other food than 'chappatties,' made of whole meal, with a little 'ghee,' or golum butter. The Swedish, Norwegian, and Russian peasants live principally on brown bread. The French peasantry, at the beginning of the present century, lived on brown bread, and the working-classes of England have only generally adopted white bread during the last hundred years.

"In descriptions of rural life in England, I often recollect the brown loaf being mentioned, and the jug of delicious new milk. I fancy I smell the honeysuckles and the sweet breath of the cows, and hear the thrushes singing as the cottagers sit down to their supper at the little table on the red tiled floor. But, alas! I fear now white bread, not of the most nourishing kind, has long replaced the crusty brown loaf, and, instead of good draughts of pure milk, children and all have to drink tea, often without a drop of milk. If county gentlemen could give facilities for the poor to buy milk, they would do good."

Dr. Parkes, author of "Personal Care of Health," mentions that the entire grain of corn is badly represented by ordinary baker's bread. He regrets that oatmeal is less used than formerly.

He tells us "that one and-a-quarter pounds of oatmeal will supply as much nitrogen and almost as much fat to the body as one pound of uncooked meat of ordinary quality, yet the meat costs ten-pence per pound and the oatmeal only threepence or fourpence. For the same money a man gets nearly three times as much nourishment in oatmeal as in meat, and the oatmeal is more cheaply cooked."

Dr. Parkes adds that "a labouring man, by ringing the changes on oatmeal, maize, peas, and beans, rice and macaroni, which is made from corn, to which may be added cheese and bacon occasionally, may bring up his children as well nourished as those of the richest people."

Attempts have been made to induce English people to oatmeal porridge, but I fear only the rich take to it. I find in Buckmaster's Domestic Economy that "in old times a peculiar sacredness was attached to bread. A house without it was said to be forsaken by the gods." This writer tells us that "white bread and new bread are wasteful," and that "our grandfathers and grandmothers ate brown bread often, barley bread and rye bread."

Most writers on food agree that we might be as well fed if we ate less meat, and more nourishing cereal food. It is in the belief that wheat-meal bread really does contain much valuable nourishment, that the Bread Reform League have united with Miss Yates in the effort to make its use more general, especially among the poorer classes.

For several years past, I have seen the whole meal or wheat-meal bread on the breakfast tables of the rich. I was told it was particularly recommended to those whose brains are kept in constant work.

I am greatly indebted to Messrs. Hill, of 59, Bishopsgate-street Within, and Albert Mansions, Victoria-street, for giving me information about the various kinds of meal. They sent me three samples of the wheat-meal flour, and some delicious "Devonshire bread." I learn from Mr. Neave Hill that the finest is wheat-meal—the sort Miss Yates advocates, is granular wheat-meal—and a third, the coarsest, is whole-meal. Twenty times as much is sold, by Messrs. Hill, of the third—the coarse whole meal bread, as others. This is eaten by the upper and middle-classes, as it is frequently recommended to those leading sedentary lives.

The only difference between the three classes of flour is in the grinding. The granular bread is smooth on the surface, and children profit much by its use. Messrs. Hill, with that benevolence and liberality which brings its own reward, have frequently endeavoured to promote the use of the whole-meal bread among the poor, even going so far as to offer it to them when one day old at the nominal price of one penny per 4lb. loaf, but they have not succeeded in popularising it among the classes to whom it would prove most useful.

If Messrs. Lockhart would sell it in buttered slices at their establishment, perhaps by degrees the poor would find out how good and satisfying it is. We must recollect that to the poor good butter is an almost unattainable luxury, and butter improves all three of these breads greatly. But as the granulated whole-meal bread certainly goes further than the white bread ordinarily bought, the money saved in the quantity of bread might be spent in a little more butter. The profits of the Bread Reform Exhibition were to be handed over to the Council to establish a Penny Breakfast Fund for poor children. At these breakfasts it was proposed to give a thick slice of the granulated bread and a cup of cocoa for a penny. The bread and cocoa certainly, together, make a substantial meal. I trust Miss Yates and the kind members of the Bread Reform League will not be discouraged if time must pass before the value of the food they advocate is generally recognised among the poor.

When Sir Walter Raleigh introduced the potato into England, in the days of good Queen Bess, he could hardly have foreseen that it would become universally used; and doubtless many at first objected to the foreign root, as some do now to the granulated and whole-meal bread. It is pleasant to think that many scientific men, many eminent physicians, and others, distinguished for their interest in their poorer neighbours, encourage this movement. Among these are Lord Shaftesbury, Dr. Richardson, Professor Tyndall, and many more.

All communications should be addressed to the philanthropic lady who devotes time and energies to promote the objects of the Bread Reform League, Miss Yates, 8, Northumberland Terrace, Regent's Park, England.

OPENING OF A SILO IN ABERDEENSHIRE.

COLONEL FERGUSON of Pitfour erected a silo last summer (under the able superintendence of his factor, Mr. Alnallie), on his farm of Lunderton. It was built as a barn, with strong stone and lime walls and a slate roof, and was divided into three compartments, each 15 feet by 14 feet, and 10 feet in depth. The partitions dividing the building into compartments were of stone and lime, 9 inches thick and plastered with cement. Drainage was amply provided for, and pressure on the ensilage was obtained by means of screws. Across each compartment were laid two old metal rails, a foot below the floor, and firmly built under the wall at each side. A strong concrete floor was laid above them, with holes in it to admit chains coming up from the rails below—one chain at either end of each rail about 3 feet from the wall. These chains extended up to the roof, and were fixed there. The ensilage, consisting of oats, peas, and beans, was packed into the compartments firmly, the chains coming up through it. When a sufficient quantity of ensilage was put in to fill the compartments, batons were laid across it closely, and over that transversely were placed two beams. Before coming up to this height the chains were attached to strong iron screws, which were taken up through the two beams we have referred to as having been laid on the top of the batons. To this a screw was applied, and, by means of it, the wooden cover was tightened down to a pressure of ten tons on each screw, or twenty tons on each compartment, equal to about 200 pounds on each superficial foot of surface. As the ensilage subsided, these screws were tightened. At the end of four days, when the subsidence had extended to three feet eight inches, the silos were opened and filled again to the top, salt being added in one of them at the rate of one pound to eighty pounds of ensilage. Each silo took in at the first filling twenty-three tons, which was the weight of crop grown on three acres of land. After the subsidence of four days seven tons more were put in, making thirty tons to each compartment. A large number of farmers were present on Saturday when the silos were opened, and they selected from the stock on the farm four calves, four cows, and four two-year-olds, to be fed on the silage for some time, and then tested as to what improvement had taken place in them.

THE FLOWER SHOW.

THE Flower Show at the Agri-Horticultural Society's gardens, Alipore, on the 7th February, was as good as any of its predecessors, and we were glad to see that it included in it a Vegetable and a Fruit Show as well. There was not such a good exhibition of seasonable fruits and vegetables as one might have expected, or would like to have seen. This may be due, in some measure, to the difficulty in inducing native gardeners to a public show. There were, however, some fine specimens of potatoes, tomatoes, and onions. The knol-khols, turnips, cabbages, and cauliflowers were passable, though as good, if not better, specimens can be seen any day at the New Market. With the exception of *tijapree* (gooseberries), guavas, and *sapota*, there is a scarcity of fruits at this time of the season, yet we cannot say that (barring guavas), there was a very good exhibition of *tijaprees* and *sapota*. The best collection of vegetables, to our thinking, was sent by Mr. Stalkart; his show of tomatoes, potatoes, and French beans was the admiration of all. Generally, there was no good show of peas. As regards the flowers, the exhibition was, as we have said, as good as any of its predecessors, though we are inclined to think that the previous night's hail-storm must have contributed greatly to mar the show. There is not the least doubt that the roses suffered considerably from the storm, and we were not a little surprised when we entered the flower shed to see such a good exhibition as we did. There were some exceedingly fine specimens of cut flowers, and, as usual, Mrs. Apar, carried away the prize for the best stand of camellias. Baboo Prosono Coommar Banerjee, Roy Bahadur, had a very fine mound of roses artistically arranged on a table, but, with a magnanimity becoming such an enthusiastic floriculturist as he is, he did not put these forward for competition. Belvedere carried away the prizes for the bridal bouquet of white flowers, and for the hand bouquet for the ball-room; while Baboo Prosono Coommar Banerjee was awarded the prize for the best bouquet of scented foliage. For the best collection of growing plants and flowers, Mr. S. P. Chatterjee obtained the Grant Silver Medal, and the prizes for both orchids and ferns were awarded to Mrs. Apar. Mr. Chatterjee, who is a well known horticulturist, also obtained the prize awarded for crotons. During the afternoon, the Countess of Dufferin, Sir Rivers and Lady Thompson, his Highness the Maharaja of Cooch Behar, and the Raja of Souburra, visited the Show, when the band of his Highness the Maharaja of Cooch Behar, kindly lent for the occasion, played several selections. Owing to the uncertainty of the weather, there was not such a large gathering as is usually seen at these annual shows. Lady Dufferin left after a stay of about 15 or 20 minutes. Annexed is the list of the prize-winners:—

GROWING PLANTS.—For the best collection of plants or flowers of any number of kinds, Grant silver medal, Mr. S. P. Chatterjee; camellias in flower, not less than 6 plants, 1st prize, Mrs. Apar; ditto, not less than 3 plants, 1st prize, Mrs. Apar; orchids in flower, 4 dissimilar kinds, 1st prize, Mrs. Apar; ditto 2 ditto, 1st prize, Mrs. Apar; roses, 12 dissimilar kinds, Belvedere, 1st prize; General Wilkinson, 2nd prize; 6 dissimilar kinds, Baboo Jagub Chunder Biswas, 1st prize; Eden Gardens, 2nd ditto; ferns, 20 dissimilar kinds, Mrs. Apar, 1st prize; Mr. S. P. Chatterjee, 2nd prize; 10 dissimilar kinds, Mr. Larmour, 1st prize; Cooch Behar and Mrs. Apar, 2nd prize; begonias, 24 dissimilar kinds, Cooch Behar, 1st prize; Mrs. Apar, 2nd prize; 12 different kinds, Mr. Larmour, 1st prize, Cooch Behar, 2nd prize; aralias, 5 dissimilar kinds, Baboo P. C. Banerjee, 1st prize;

dracaenas, 6 dissimilar kinds, Cooch Behar, 1st prize; Eden Gardens, 2nd prize; crotons, 24 dissimilar kinds, Mr. S. P. Chatterjee, 1st prize; 12 dissimilar kinds, Mr. Norman, 1st prize; 12 kinds, new and rare varieties, Mr. Seran, 1st prize; Mr. Bradley, 2nd prize; verbenas, 6 dissimilar kinds, Eden Gardens, 1st prize; Belvedere, 2nd prize; asters, Eden Gardens, 1st prize; Belvedere, 2nd prize; pansies, Belvedere, 1st prize; Eden Gardens, 2nd prize; phloxes, Belvedere, 1st prize; Eden Gardens, 2nd prize; petunias, Eden Gardens, 1st prize; Eden Gardens, 2nd prize; portulacacas, Belvedere, 1st prize; Eden Gardens, 2nd prize; geraniums, Eden Garden, 1st prize, Belvedere, 2nd prize; violets, Eden Gardens, 1st prize; Belvedere, 2nd prize; foliaged plants, 10 dissimilar kinds, Mr. Larmour, 1st prize; Mr. S. P. Chatterjee, 2nd prize.

CUT FLOWERS.—Camellias, best stand of not less than 6 flowers, Mrs. Apar, 1st prize; Baboo P. C. Banerjee, 2nd prize; best stand of not less than 4 flowers, Mrs. Apar, 1st prize; Roses, best stand of 24 dissimilar kinds, Barrackpore Park, 1st prize; Belvedere and Baboo P. C. Banerjee, 2nd prize; best stand of 12 dissimilar kinds, Baboo P. C. Banerjee, 1st prize; Belvedere, 2nd prize; best stand of 8 dissimilar kinds, Mrs. Apar, 1st prize; bridal bouquet of white flowers, Belvedere, 1st prize; Baboo P. C. Banerjee, 2nd prize; hand bouquet for ball-room, Belvedere, 1st prize; Mrs. C. R. Hill, 2nd prize; bouquet of scented foliage, Baboo P. C. Banerjee, 1st prize; Mrs. C. R. Hill, 2nd prize; heliotrope, the best stand, Mrs. Apar, 1st prize; Mrs. C. R. Hill, 2nd prize.

SPECIAL PRIZES.—Tree Ferns, Mrs. Apar, President's prize; ferns, Mr. G. Norman, Mr. Larmour, and Mr. S. P. Chatterjee; foliage plants, Mrs. Apar and Mr. J. Norman, President's prizes; best collection of foliage plants, Belvedere; ferns in glass-case, Mr. G. Norman; new heliotropes, Mrs. Apar; medicinal plants, Baboo P. C. Banerjee and Aubinash Chunder Sen; table decoration, Mrs. C. R. Hill; orchids, Baboo P. C. Banerjee; dianthus, Eden Gardens and Baboo P. C. Banerjee.

FAIR TRADE.

[BY MR. W. J. HARRIS, M.P.]

THERE is at the present time a wave of doubt passing over the nation. The doctrines of political economy as taught in this country are being rudely assailed from many quarters. The agriculturists are holding meetings and passing resolutions in favour of a return to limited Protection. The manufacturers are loud in their complaints of the badness of trade. Working-men are resisting lower wages, thinking they can make laws for capital and keep their own position unassailed. The time is, perhaps, in this respect auspicious for such a subject to come to the front, in consequence of the large addition of voters from the wage-earning classes. The doubts that are permeating society will come more quickly to the front, and the next election may very possibly be fought out on the issue. Free Trade, as it is called in England, means that "we should take care of our imports," with the expectation that "our exports will take care of themselves." That is its only defence. We have chosen to be dependent on foreign commerce, while all other nations base their wealth on home development. Everyone acknowledges that between tradesmen reciprocity ought to exist, and it only requires to carry the idea a step further to feel that the same is true as regards nations. We are, however, told that our policy has enabled us to retain as our customers the non-manufacturing nations. The last year or two has shown that even this is not so. We are daily being shut out of our own old markets and our new markets are daily being more severely competed for. We are consoled by being told that the great continent of Africa is comparatively unexplored, and that we only have to be first in the field to have the custom of 200 millions of half-naked savages. Germany and France, at the same time, are plying the said half-naked savages with their own inducements, and, among many others, they will be able to urge that they did not kill four thousand of them in one day for no reason that has ever yet been explained. Where else are we to seek for new outlets? The moon offers us an unexplored market, but we can't get there; and even if we found the means of doing so, our competitors would quickly follow us. Under these considerations it is as well to turn back to the date when this policy was first recommended by the powerful voice of Richard Cobden, and see what reasons he gave for his belief in free imports. In a speech which he made in London on February 18th, 1844, he uttered these words:—

"The effect of a Free Trade in corn would be this: It would increase the demand for agricultural produce in Poland, Germany, and America. That increase in the demand for agricultural produce would give rise to an increased demand for labour in those countries which would tend to raise the wages of agricultural labourers. The effect would be to draw away labourers from manufacturers in those places."

Here are Cobden's reasons for his policy very clearly set forth; and, after forty years' trial, let us compare the actual result with what he foresaw. Germany is now underselling us in nearly every market in the world, and specially in our own. America sends us the corn but declines to take payment in our manufactured goods. In place of doing so she offers the inducement of her protected market to our best artisans and teaches her own people to make for themselves what Cobden thought she must buy from us. The trade between the two countries presents such extraordinary figures during the last eight years that they ought to be known by every voter in the kingdom:—

Imports of American produce from United States during 4 years, 1870-83	£732,000,000
Exports—British re-exports of foreign produce thereto	£285,000,000
	£447,000,000

One wishes that Cobden could rise from his grave and see these figures, and without being carried away with the cant of Radicalism, he would express his feelings that he would carry himself back to those eloquent speeches which he made, assuring us that "we only had to go the extreme length of admitting the labour of every foreign nation without let or hindrance, and that they all would follow our example within a very few years." Would he not say, "My children, my advice to you was good when you were so far ahead of other nations as you then were. You are now living under thoroughly changed circumstances. Use your brains as I used mine, but avoid prophecy. Your first duty is to see that your wage-earning population is in a state of progression, and not of retrogression. Remedy the most evident evils before you make radical changes. Bear in mind that every man in this country wants cheap food and full work. Know that in order to have the latter you are bound to import raw materials at their lowest cost. If your agriculture is failing, see how you can relieve it by relaxation of its unequal burdens before you proceed to tax the staff of life. Other nations know well your powers of retaliation; don't use those powers to the utmost until they have had complete time to reconsider the whole position."

Can it be construed into a wrong that we are doing to the great dead man to suggest that these might be his kindly words? If we thought it were, we would not write them; but Cobden was a man of great common sense, and, moreover, he was a man whose love for his country was greater than his attachment to party.

The real mistake we have made is to call our present system 'Free Trade' at all. It is simply free import. Free Trade is free exchange. Free exchange will never be attained, for this reason, viz., that it obliges nations to tax themselves unequally, and therefore the nation that had the smallest national debt and the fewest wars would in the long run win. If all nations were free from debt, and the millennium had arrived, free exchange would be far the happiest state for all. Next to free exchange comes reciprocity, and reciprocity we may obtain, first, with our colonies; and after that with other countries; but we shall never have it, if we shout from the housetop that we will never retaliate.

The first thing we have to do is to protect our own market. Fortunately, in doing this by a tax on imported manufactures, we help the poor without doing material injury to the rich. We encourage British manufacturers to endeavour to rival the foreigner in artistic design, and when once the start is made in superior workmanship, we can leave the rest to the talent of our countrymen. Goods will soon appear in our shops of English make, which will please and satisfy the rich as much as those made by the foreigner.

Economists tell us that the foreign workman will then compete with us more successfully in our own exported handicrafts. They forget that it is easy enough for the young English workman, with his improved education, to attain to the higher taste and higher class of foreign manufacture; but that it is not only hard but most distasteful for the foreign workman, who has been brought up to art-workmanship to descend to simple labour. Free Trade has denied to our artisans the higher class work, and left to us the lower class. We want both, and the attainment of both would not only secure employment for our increasing population, but would also raise their minds and educate their senses.—W. J. HARRIS.—*England*.

SHIPMENTS OF BULLION TO THE EAST.

THE subjoined is from an annual Circular just issued by Messrs Mocatta and Goldsmid. Their statistics of the movements of the precious metals are valuable:—

"The silver market has again been characterised during the past year by remarkable steadiness for the first ten months, followed by a rapid decline in November and December, from which, however, in the last few days, there has been some recovery. The price, which at the end of 1883 stood at 51d., fell in January to 50½d., but immediately improved, and on the 22nd February reached the highest point of the year—51½ per oz. Soon declining to about 50½d., it remained between 50½d. and 50¾d. with slight fluctuations till the end of October, after which a rapid fall took place until the middle of December, when the lowest rate—49½d.—was touched. This decline, which originated in the low exchanges in India, and the consequent reduction of the rate at which the India Council were willing to sell their drafts, became more marked on the announcement of the Secretary of the Treasury in America that another attempt would be made to suspend or repeal the 'Bland Bill,' which requires the coinage of silver dollars to the extent of two to four millions per month. The injurious effect of this report has to some extent subsided, as it is not thought that any action can be taken during the present Session of Congress, which extends to the middle of March next. The average for the year is 50 11-16d. per oz., differing very slightly from that of last year, which was 50 9-16d.

"The exports to India (£5,750,000) have been considerably in excess of those of 1883, which were under four millions, and large purchases have been made from time to time for Spanish account and for home coinage, which have supported the price of silver at times when there was a temporary cessation of the Indian demand.

"The bills of the India Council were taken freely in the early part of the year at rates ranging from 1s. 7½d. to 1s. 7d., but in the latter half the amounts taken were limited, the minimum having been kept rather higher than the state of business enabled the banks to pay. Lately, however, the minimum has been reduced to 1s. 7d. per rupee, and large sales made. The total since Jan. 1 is £16,088,000, against £19,300,000 in 1883.—*Home and Colonial Mail*.

THE POONA HORSE SHOW.

THE following resolution has been forwarded to us for publication:—

Bombay Castle, 20th January 1885.

Letter from the Commissioner, C. D., No. R-5970, dated 28th November, 1884—submitting, with his remarks, a report by the Honorary Secretaries on the Horse Show held at Poona on the 30th September and 1st October, 1884, together with the report of the Judges of the Show.

Memorandum from the Commissioner, C. D., No. R-6195, dated 6th December, 1884.

RESOLUTION.—Government in their Resolution No. 5955, dated 23rd June, 1884 sanctioned the proposal of the Commissioner, C. D., that the Poona Cattle Show should be held separately from the Horse Show. The reports now to be considered relate only to the latter show, which was held on the 30th September and the 1st October last.

2. It is satisfactory to observe that the show was better attended and more successful than that of the previous year. The number of animals exhibited in the Breeders' Classes rose from 192 in 1883 to 304 in 1884, the increase being evenly distributed throughout the different classes. There was, however, very little improvement in the condition of the animals exhibited, the only good classes being those of yearling colts and fillies. The Commissioner suggests, with a view to obtaining better results in return for so much labour and expense incurred by Government on horse-breeding operations, that castration of inferior stallions should be induced by levying a tax of Rs. 5 on every entire horse that has not been passed by a Government Veterinary Surgeon. His Excellency the Governor in Council is of opinion that the practice of castrating horses unsuitable for breeding purposes, which is required in the interests of owners of horses, can be made popular only by convincing the persons interested of the advantages of it, and that it cannot be legitimately enforced in the manner suggested by Mr. Robertson.

3. There was an increase of 24 in the number (43) of geldings exhibited as compared with the number in the previous year, but little or no improvement in the quality of the animals. His Excellency the Governor in Council approves of the suggestion of the Honorary Secretaries and the Judges that in the classes for geldings prizes should in future be awarded to deserving animals only, and that the balance of the amount set apart for these prizes should be distributed, as considered fit by the Judges, among the unsuccessful exhibitors. The number of mules exhibited was 19 as against 15 in 1883, and that of mares used for mule-breeding, 11 against 9; but the animals looked in poor condition and of inferior quality.

4. There were in all 49 animals shown in the Fancy Classes as compared with 35 in the previous year. The majority of the Judges propose that the prizes for these classes should be discontinued, with the exception of those for chargers. But the remarks made by the Honorary Secretaries and the Commissioner on the point show sufficiently the value of these classes in making the show attractive, and the Governor in Council concurs with them in considering that it would not be advisable to discontinue the offer of prizes for them.

5. The question of establishing a stud farm and purchasing on behalf of Government the best young stock exhibited is one for consideration in the Military Department, to which the papers forwarded by the Commissioner, C. D., with his memorandum, No. R-6195, dated 6th December, 1884, and also the remarks of the Commissioner and Lieutenant-Colonel Hogg on the subject, should be communicated.

6. After defraying all expenses, which amounted to Rs. 7,236, a surplus of Rs. 734 remained in hand to be expended on the next show, for which the usual Government grant, Rs. 5,000, is sanctioned, with the concurrence of Government in the Financial Department, on the understanding that a portion of the grant will be set apart for expenditure on the cattle-show of 1885.

7. The thanks of Government should be conveyed to the Judges and to the Honorary Secretaries for the satisfactory arrangements made by them.

J. MONTEATH,
Under-Secretary to Government.

THE FALL IN PRODUCE AND RAW MATERIAL DURING 1884.

THERE is hardly an article of produce which has stood the pressure of over-increasing stocks and abounding protection. Sugar is from 30 to 40 per cent cheaper; coffee has declined nearly 20 per cent; tea, which had previously been declining in value for a series of years, has lost another 4 per cent or so; and wheat, which in December, 1883, had receded to 40s. per quarter, is now barely 31s. This represents a reduction in price of more than 20 per cent. In the case of raw materials, such as cotton and wool, the most important of all next to iron, the fall has not exceeded from 1 to 3 per cent, but then it is a reduction upon prices already low, so that the encouragement which the importer stood so much in need of has not been given to him. There is but one article, flax, whose price has increased by about 7½ per cent since December, 1883, but all through the first half of the current year, it also was depressed. Hemp has declined about 6½ per cent, jute about 2½ per cent, and raw silk 24 per cent. It has been much the same with metals. Iron, it is well known, has been low in price for several years, and steel was considered to be phenomenally depressed twelve months ago. No change for the better, however, took place during the first ten months of the current year. On the contrary, prices continued

to shrink until Scotch pig iron touched 40s. and steel rails 45s. per ton. A slight indication of improvement has been visible within the last few weeks, and Cleveland bar iron alone remains at the lowest figure of the year. But notwithstanding this improvement, Scotch pig iron is still 4 per cent under the price of a twelvemonth ago, and the improvement in steel rails is little more than 3 per cent. As for other metals, the fall in some of them during the year has been nearly as disastrous as that in wheat or sugar. Chill bar copper has fallen 13 per cent in price in twelve months, and is now 27 per cent lower than it was three years ago. Pig lead has receded 12 per cent within the year, and Straits tin about 13 per cent. Little definite idea is, perhaps, given by statistics of the losses which this nearly universal shrinkage has thrown upon importers, and data complete enough to enable a correct estimate of the difference in money between now and a year ago do not exist. Were we, however, to assume that the imports of the country had lost in value only 5 per cent taken all round, it would mean that import merchants had received less by £16,500,000 for a like quantity of goods than they did during the preceding twelve months. This can scarcely be considered an excessive estimate, and a diminution of values to even this extent must have entailed wide-spread losses in that branch of business. The internal trade and manufactures have suffered to at least as large an extent.

In the following table the quotations are given of the leading raw products where the changes have been most conspicuous within the past year—at three separate dates—enabling our readers to contrast the prices of last month with those current at the beginning of 1883 and 1884:—

		1883.	1884.	1884.
		Jan. 7.	Jan. 1.	Dec. 1.

—(*Home and Colonial Mail*.)

THE IRON TRADE IN 1884.

DURING the year 1884 the movements in the iron trade have been less rapid than in many previous years, and have been shown more in the extent of production than in the price. There has been, it is known, a considerable reduction in the production—the decrease in the output in the Cleveland and Durham district alone being about 25,000 tons, whilst the statistics of the Scottish ironmasters show that there has been a declension in the number of the furnaces in operation in Scotland. Generally the tendency in other districts has been in the same direction, and when the official figures are compiled, a considerable reduction in the output will be shown from the maximum production attained in 1883. But prices have been fairly steady, especially in Cleveland, where a slight increase in the price in the early months of the year has been little more than counterbalanced by the fall in the later months, when shipments have been less, and when the stocks in the hands of the makers and in the warrant stores have been increased. The trade in all its centres has felt the effect of the diminished demand of manufactured iron for ship-building, which in the past four years has been one of the chief supports of the iron trade, especially in Durham. It is more in the direction of the home trade that the lower demand is known, so far as the crude iron trade is concerned, than in that of the foreign, for though the latter has declined, the fall is small compared to that of the former. In the Cleveland and Durham districts, for instance, the fall in the production of pig-iron of all kinds may be put at a quarter of a million tons, as we have said, but there is a more than equivalent fall in the consumption of that pig-iron for the production of malleable iron, and the decline in the quantity of iron exported is very slight. In Scotland, where a larger portion of the production is devoted to other than forge uses, the proportion is different, but there is generally a large sale of pig-iron to the United States, and from that country the demand has been small and dwindling all the year, until now it must be at about its lowest ebb. The hematite-producing districts of the north-west have also felt very seriously the loss of that market, but in the latter months of the year there have been slight and fitful signs of some recovery. In Wales, the dulness in the demand for steel has affected the crude iron market, and thus through the whole of the producing centres there has been, from one cause or other, a depression that has shown itself either in lessened production, or in increased stocks in the hands of the makers.

In prices, the movement in Scotland has been downwards in the year, despite the fact that the number of operative furnaces has been reduced by nearly ten per cent. At the beginning of 1884 the price of warrants was 42s. 10d., and in the present year it has risen and fallen, the closing price being not very much

below that amount; but there have been falls of more moment in the prices of iron of special brands, and had it not been for the collapse of several firms of "hears," the latest price of the warrants might have shown a fall more important. In the Cleveland and Durham district the steadiness of the price has been very remarkable, when it is remembered that the stocks in store and in the hands of the makers have shown a rather heavy increase. For January the average price was about 17. 16s. 6d., and it rose to its highest, 17. 17s. 2d., in March, and it has irregularly fallen by the end of the year to—for the last month—17. 16s. It is long since the extent of the movement on either hand was so small as it now has been, and from that steadiness, some are inclined to draw the deduction that there will be an early increase in the price, one that will show itself when the demand begins to set in for the next shipping season.

But the position of the iron trade as a whole depends much more on the demand from the outside than is recognised by those who hold that anticipation. It may be fairly believed that the worst has been known of the depression in the ship-building trades, and that there will be some increase in the demand for manufactured iron and steel for ship-building purposes; but we now make so much pig-iron that we need an outlet for a large part of our production in that form. We can scarcely hope for much immediate increase, though the stocks that are held by many foreign countries are very shrunken, and any return of activity in the trades would find them with their producing capacity much reduced, and they would have to draw to some extent on our stocks of raw iron. It is impossible to prognosticate the period of recovery of these foreign consumers; but as the fall has been sharp it may be hoped that the recovery will be speedy; and as the exports of crude iron have now fallen to a very low ebb, it is to be looked upon as a probability that the recovery cannot be very long delayed. All over the world the production of iron has fallen this year, and though the use of the crude iron may have decreased for a time, the actual consumption of the finished articles has gone on as usual, and shows that tendency to increase that is its normal attribute. More and more the fleets of the world are of metal; the area of the use of iron and steel on the railway is being constantly increased, and thus the quantity that is needed to replace that worn out grows from year to year. We cannot hope that the United States will for some months to come recommence railway construction on any scale of great magnitude, but in the East we ought to have a much larger demand—a demand that the rail-mills of England should first be looked upon as likely to supply. With any recovery in our own ship-building yards, and with the enlarged use of iron and steel for repairs and renewals, there should be an accession of activity that would benefit the whole of the contributory trades. The manufactured articles are now at prices that must be looked upon as at the ebb, and these low rates should give an enlargement of the purchasing power of the users, whilst the belief that they are at their lowest will tend to bring into the market orders that have been kept back. The year 1884 has not brought down the price of crude iron much lower, but it has extended the low prices to plates, rails, and other productions, in which the declension is much greater than that of pig-iron in the year. Iron plates, for instance, are now lower than at any time the records show, and it is to that low price, in part, that the few orders for vessels that have of late been given out are due. In a degree, that remark applies to other goods; and already the effect of very low prices is seen in the closing of some mills that cannot work to profit at them. This will steady the market, and may in the end give the stimulus for which some branches of trade wait. Lessened production and a consumption that has a normal growth will in the end equalise themselves, and alter the course of prices, and the year 1884 has tended to produce that equalization. —*Evening Standard*.

A SKILFUL SURGICAL OPERATION.

THE American Ambassador at Vienna, Mr. Kasson, has lately forwarded to his Government an interesting account of a remarkable surgical operation lately performed by Professor Billroth, of Vienna, which, wonderful to tell, consisted in the removal of a portion of the human stomach, involving nearly one-third of the organ—and, strange to say, the patient recovered—the only successful operation of the kind ever performed. The disease for which this operation was performed was cancer of the stomach, attended with the following symptoms:—The appetite is quite poor. There is a peculiar indescribable distress in the stomach, a feeling that has been described as a faint "all gone" sensation; a sticky slime collects about the teeth, especially in the morning, accompanied by an unpleasant taste. Food fails to satisfy this peculiar faint sensation; but, on the contrary, it appears to aggravate the feeling. The eyes are sunken, tinged with yellow; the hands and feet become cold and sticky—a cold perspiration. The sufferers feel tired all the time, and sleep does not seem to give rest. After a time the patient becomes nervous and irritable, gloomy, his mind filled with evil forebodings. When rising suddenly from a recumbent position there is a dizziness, a whistling sensation, and he is obliged to grasp something firm to keep from falling. The bowels constive, the skin dry and hot at times; the blood becoming thick and stagnant, and does not circulate properly. After a time the patient spits up food soon after eating,

INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA :—SATURDAY, FEBRUARY 21, 1885.

[No. 8.]

Crop and Weather Report.

[FOR THE WEEK ENDING THE 11TH FEBRUARY 1885.]

General Remarks.—Rain has fallen generally throughout the Punjab, Bengal and Assam, in Sind, and in two or three districts in the North-Western Provinces and Oudh. In British Burmah there has been rain in several places.

In Madras agricultural prospects are still bad in Bellary and Anantapore. Elsewhere in the Presidency the crops are in fair condition, but the outturn of the harvest is generally below the average. In Mysore prospects are fair, but more rain is wanted for the crops in the Kolar and Tumkoor districts. There is no change in the situation in Coorg.

In Bombay the *rabi* is being reaped in parts of Ahmednugger, Sholapore, Belgaum, and Kaladgi, and the standing crops are generally in good condition. In the Berars, the Nizam's territories, the Central India and Rajpootana States, agricultural prospects continue satisfactory.

In the North-Western Provinces and Oudh, the Punjab, and the Central Provinces, prospects remain unchanged.

The prospects of the *rabi* are generally favourable in Bengal, though in some districts damage has been done by insects. Reaping of mustard and pressing of sugarcane continue.

In Assam ploughing for *aus* cultivation is in progress, and the mustard crop is being gathered in two districts.

Cholera is abating in the Tanjore and Madura districts, but is increasing in Coimbatore. Small-pox is prevalent in several provinces. Otherwise the public health is generally good.

Prices are fluctuating in the Punjab; elsewhere they are generally stationary.

Madras.—General prospects fair except in parts of Bellary and Anantapore.

Bombay.—*Rabi* harvest in progress in parts of Ahmednugger, Sholapore, Belgaum and Kaladgi; standing crops injured by frost in parts of Hyderabad, by mildew in parts of Nasik, by rust and blight in parts of Shikarpore, and by insects in parts of Poona and Rutnagri; scarcity of fodder and drinking water continues in several talukas of the Southern Mahratta country districts; cholera in parts of 6 districts, small-pox and cattle-disease in parts of 10, and fever in parts of 13 districts.

Bengal.—There has been rain in almost every district of the Province. It has generally benefited the *rabi* crops and facilitated the ploughing of *aus* crops; potatoes have been injured in places where the rain was heavy; reaping of mustard and pressing of sugarcane are going on, and in some places the latter crop is being planted; prospects of *rabi* crops generally favourable, but in a few districts they are being damaged by insects; price of rice almost stationary; general health good, though cholera and small-pox prevail.

N.-W. P. & Oudh.—Blight and mildew present in some districts; prospects generally good; markets well supplied; prices easy; public health good.

Punjab.—Health and crop prospects good; crops in Rawalpindi tahsil threatened with blight owing to excessive rain; prices falling in the Hissar, Delhi, and Peshawar districts, rising in Ferozepore, and stationary in the remaining districts of the province.

Central Provinces.—There has been no more rain, but it is still cloudy in some districts; prospects continue favourable; prices are generally stationary; slight cholera and small-pox in places.

British Burmah.—Slight small-pox in Bassein, Henzada, Thayetmayer, and Mergui; slight cholera in Henzada, Thongwa, and Prome; elsewhere public health good; slight cattle-disease in Bassein; elsewhere health of cattle good; rainfall in Rangoon, Thongwa, Bassein, Pegu, Toungoo, Tharrawaddy, Moulmein, Shwegyin, and Mergui from 0.7 to 1.70 inches; elsewhere no rainfall.

Assam.—Weather cloudy; nights cool; mustard being gathered; lands being ploughed for *aus* cultivation; public health fair.

Mysore and Coorg.—In Kolar and Tumkoor districts crops suffering from want of rain, otherwise prospects fair; public health generally good; prices continue to rise.

Berar & Hyderabad.—Weather clear; prospects of *rabi* crop favourable; cotton-picking and *jowari*-threshing continue; wheat 22, *jowari* 26 seers per rupee.

Central India States.—Weather cloudy but much colder; prospects of crops and health good; prices steady.

Rajpootana.—Weather still continues cold; health good, and crop prospects good.

Letters to the Editor.

A PLEA FOR THE DATE PALM.

TO THE EDITOR OF THE PIONEER.

SIR,—Between 1889 and 1872, I distributed several varieties of seeds of the *true Arabian date palm* to all the district officers in Oudh. These seeds were sent by the Political Resident in the Persian Gulf at the request of the Government of India. Many of the palm which resulted from those seeds appear now to be flowering, and in the way of bearing dates. I therefore ask that you may be good enough to allow the following lines to appear in your columns, being the readiest way of diffusing information regarding the proper mode of cultivating this palm, and fertilizing its flowers. I consider this a very important subject. There is now a large number of Arabian date palms in Oudh, which, for want of sufficient knowledge about cultivating them, and otherwise dealing with them, are thought to be of little value. I need hardly mention that the flowers of the date palm are of two sexes, the male and female flowers being borne on *different* trees. The Arabian method of cultivation is this: Only female trees are planted, in large groves, the palms being put 12 or 15 feet apart. In order to do this, they plant only *offsets* (not seeds, as the sex of these cannot be known before they flower) taken from the foot of the female trees, when these offsets have attained the weight of three or four seers, that is, after five or six years or more of growth on the parent tree. I found September the best season for planting offsets in Oudh. They are then watered daily, or less often, till they strike, and afterwards at longer intervals. In the Persian Gulf groves consist of 80 to 200 palms. They should be protected from cattle; other crops can be grown between the rows; and there should be some means of irrigating the palms. In short, after striking, the trees should be treated in every way as other fruit trees, from which superior fruit is desired, each palm having a large *thala*, which should be periodically filled with a top dressing of any old manure available, such as cow, horse, sheep, goat, or even fish manure. Only the *decayed* lower leaves should be removed, and *none* of the green leaves should on any account be removed, as these are the lungs and stomachs of the trees. It should not be forgotten that fruit from offsets, if they are properly cultivated, will be like that of the parent tree, while fruit from *seedlings* will vary. Seeds can be sown in beds a few inches apart, and in a year, during the rainy season, transplanted into other beds, two or three feet apart, and finally planted out in groves 12 to 15 feet apart. The Arabs rely on *artificial* fertilization only to ensure a crop of dates. The male trees may be any distance, and may have flowered a month or two before the females. The Arabs say that the male bunch of flowers is *mute* when, by "pressing it, a faint rustling sound is elicited. Also, if a slit is made in the margin of the flower spathe, a peculiar odour is detected." Then the bunch of male flowers is removed from the tree, the spathe split open, the sprigs of male flowers carefully removed, and placed in a suspended basket, protected from draughts and allowed to remain 20 to 24 hours before being used. As soon as the female flowers have burst their enveloping spathe, they are fit to impregnate. The cultivator then climbs the tree, and inserts two or three male sprigs into each female bunch, and secures them with a strip of palm leaf. Date palms produce from 12 to 24 bunches of female flowers, but eventually only from *eight to twelve bunches of dates* are allowed to remain on each tree. If more are left, the dates,

like other fruit, will be small, and many will fall off. They say that date pollen in this way will keep fertile for one or two months, and used as occasion requires. The male flowers should, however, be slightly moistened with water to prevent the pollen from being scattered too readily while being used. In the Persian Gulf artificial fertilization is considered a most important operation, otherwise the fruit is "abortive or blighted," without stones, and insipid. After fertilization the trees are not watered for six or eight weeks. I should wish now particularly to mention that in Arabia (and presumably in Oudh also) there are three distinct classes of date palms. (1) Such as do not ripen their dates beyond the red or yellow stage, firm and dry, called *kharek*. This occurs in June and July. The dates of this class can only be preserved by cooking or curing in other ways. (2) Such as turn brown, and become soft and juicy, but go no further. This occurs in August. These dates are called *rutub*. Even in Arabia this class of dates will not keep beyond a few days, as they turn sour. They can only be made to keep by proper curing. (3) Such as go beyond the *rutub* stage, and ripen thoroughly into the *khorma* stage, which is sweet and semi-dry. This complete ripening in Arabia occurs in September. It is this last class of dates, which, after being collected and exposed in the sun, to rid them of their extra juices, are carefully packed in boxes and exported to Europe and America, without any further preparation. It should not, however, be forgotten that *khorma* dates have, of course, to pass through the two previous stages, namely, of *kharek* and *rutub*. All the classes of dates, at all stages, are edible and nourishing, and the Arabs feed on the one or the other kind all the year round. The shrivelled, unripe droppings, or such as are not fertilized, and therefore insipid, are given to goats, sheep, and cattle. In the Gulf, there are upwards of a hundred varieties of date palms. And, as something like fifty varieties of date seeds were sent to Oudh, there are sure to be in almost all the districts many puzzling classes and sub-classes of date palms. In the Lucknow Horticultural Garden alone there upwards of 252 seedlings, varying from 13 to 16 years old; and 112 from imported offsets, from 12 to 13 years old, and I am informed that there are hardly two alike. In the districts there are only seedlings of the foregoing ages. Unfortunately, however, those in the districts are scattered, and unless artificial fertilization be practised, little will be known of their worth. The male flowers of the *khajoor*, or jungle date palm, are as good as any for purposes of fertilization, but the plants resulting from such crossed seed, would be mongrels, although not improbably very good mongrels. With regard to protecting the ripening fruit from the depredations of bees, wasps, birds, and squirrels, the Arabs do little. Their plantations are on an immense scale, and the loss from these causes they consider unimportant. Sometimes they envelop the ripening bunch of dates in the leafy branches of some bush, sometimes in bags made of date-leaf matting; but where very choice varieties are grown, and the number of trees is small, they cover each bunch with a gunny bag. Squirrels in India are a great nuisance, and would tear the gunny bags and use the fibre for making their nests. Thorny branches of *babool* and *bar*, tied round the palm stems, would, however, prevent them from getting up. I will not further take up your space with detailing the different recipes for preserving and curing the different kinds of dates. I shall only give the names of the preserves, and shall be glad to give further information to any one wishing to know more about them. They are the following: *Khorma* (such as are exported to Europe), '*khorma sheerub*,' '*khorma sub-roed*,' '*khorma post kandah*,' '*morrabba khorma*,' '*matgoogale*,' '*kharek pokhta*.' As stated before, the *kharek* and *rutub* kinds cannot be kept, except by cooking or curing them in various ways. I have written all this because I think the introduction of the date palm a most important matter. Of all the trees that have been introduced, with the view of providing something edible in famine times, this I think is the one which promises most. In Lucknow the best and finest crop of dates was produced when there was a scarcity of rain in 1878. In that year very little rain fell before October. The date fruit appears to have all the ingredients for nourishing the body. We have been told that during the late Russo-Turkish war, the Turks marched and fought upon no other food. Poor Arabs live upon little else, and feed their camels on the same. In addition to food this wonderful tree affords materials for baskets, mats, and bags, and hats and caps, for hutting and thatching, and for fuel, and also a fibre for ropes, and timber for various purposes. In case of need, and at the expense of the fruit, it will also provide sugar, molasses, and spirits. Although in some parts of India, owing to excessive rain at the ripening time, the dates may not come up to the *facile princeps* of their kind—the *khajoor* date of 'El Hesa'—there remains no doubt whatever that

under any circumstances the palm can furnish abundant food of a very valuable kind, as far as nourishment is concerned, and that it is the best tree that can be introduced for famine times. I was told at Lucknow that one of the bunches was *ek-admi-ka-bajka*. Groves of such palm in times of scarcity would be far more valuable than mango groves, as what is not eaten at once can be readily cooked and preserved for future use. The age of the date palm is, I think, unlimited, and unless blown down in storms, when they are singly placed, they go on fruiting for ever. As there are now some of these date palms in almost every district of Oudh, they are very valuable as centres of dissemination if the flowers be fertilized. They can be multiplied both by offsets and by seeds. Although the latter might not, perhaps, reproduce the exact qualities of their parents, it is well known that they produce useful and often valuable varieties. Of course a few trees are of little value except for propagation, but hundreds of thousands of date palms would certainly be of immense value.

E. BONAIVIA, M. D.

Etawah, 7th February.

Editorial Notes.

ACCORDING to a contemporary a company, called the Cairns Tobacco Co., have for some months past been quietly proceeding with their plantation on the Barron river and with marked success. Operations were commenced shortly after the conclusion of last wet season, when about four acres of land were cleared and planted as an experiment; the best Virginia seed, Oronoko, and Hester alone being selected wherefrom to raise plants. These, when planted out, were placed 3ft. apart, and have yielded eighteen to twenty leaves of an average size of 3ft. 4in. long by 2ft. wide per plant, which gives an average of a ton and a quarter of tobacco per acre, the yield this year from the four acres planted being nine to ten tons. As soon as it was found how well the plants thrived, a drying-shed of galvanized iron 70ft. by 40ft. was erected, and machinery for the manufacture of the raw material ordered from Sydney, the latter of which is only just coming to hand. Samples of the tobacco have, however, been forwarded to Sydney and Brisbane, where it has been pronounced by experts to be of the finest quality, and valued at from £70 to £80 per ton for dry leaves, at which price the Company have received an offer to take their crop. The kinds of tobacco proposed to be manufactured on the plantation at present are the usual twist, cake, and cut tobaccos, and it is anticipated that the Company will very shortly be in a position to offer tobacco of their own manufacture in the market. The success that has attended their experimental efforts has determined the Company to prepare for more extended operations, and next year cultivation will be proceeded with upon a much larger scale.

.

Of the entire products of the vegetable world there is, perhaps, none which can compare favourably with the cocoanut palm in the variety of uses to which it can be converted for all the ordinary purposes of life. The period during which it yields its fruits is the same as that allotted to the life of man—three-score years and ten; after this it ceases bearing. The trunk is then cut down, which is utilised by the peasant for building his hut and the cow-shed, and the leaves are used to thatch them, slips of the bark are used as bolts and bars, and the leaf stalks are used to fence the little plant of chillies, tobacco and pine with which his habitation is generally surrounded. A rude net of coir strings made from the husk in which the fruit is enclosed answers the purpose of a bed in which the infant is swung to sleep, the meal of rice and scraped cocoanut is boiled over a fire of cocoanut shells and husks, and is poured into a dish of the plaited green leaves and eaten with a spoon scooped out of the nut shell. When the peasant goes on a fishing excursion at night, his net is of cocoanut fibre; the torch that lights his way and helps him in his labour is a bundle of dried cocoanut leaves and flower stalks—his little canoe is a trunk of the tree hollowed out by his own hands. When thirsty he helps himself to the juice of the young nut, and when he is hungry he eats of its soft kernel. If he wants to take a cup that cheers him up and is slightly inebriating, he quaffs a little of arrack distilled from the fermented juice of the palm, and if

inclined for a dance he does so to the accompaniment of rude cocoanut castanets. The very toddy which he takes to drive away weariness yields him vinegar wherewith to flavour his curry. The oil made of the kernel acts as a remedy against the cold, and is therefore well rubbed all over the body to preserve vitality, infants especially being well besmeared with it, and exposed to the rays of the sun to fortify them against variable climatic influences. A coarse description of sugar or jaggery is manufactured out of the kernel, which goes to flavour his coffee, and the milk of the nut does duty for that of the cow. The very lamp which lights his hut is made of cocoanut shell, and fed with cocoanut oil. The few rude furniture of the peasant's habitation, the very doors, windows, shelves and chairs, are all made from the wood of the tree. His spoons, his forks, his basins, his mugs, his salt-cellars, his jars, his child's money-box—are all derived from the same source. Over his couch, when born, and over his grave, when he has done with the world, a bunch of cocoanut blossoms is hung to charm away evil spirits. The proverb that "the cocoanut palm has ninety-nine uses, and the hundredth cannot be discovered," is nothing but the crystallised experience of hundreds of generations.

* *

THE drug known as Papain, the active principle of the *carica papaya* and its valuable properties, have for the past some years attracted a good deal of attention from the members of the medical profession all over Europe. The following notes by Professor Fiukler of Bonn who has carried out some careful experiments with it will be very interesting to our readers. He says:—I have for several years turned my attention to the chemistry of digestion and ferments; it was, therefore, only natural that I should take an interest in papain, which I find dissolves albumen and fibrine in acid, alkali, and pure water. I test the whole of the papain in my laboratory, and I guarantee that it will dissolve in pure water 1,000 times its weight of fibrine. This preparation is different to any other I have tested, because it is not acted upon by exposure to the atmosphere, and will keep for some time. Papain dissolves the membranes of diphtheria and croup very rapidly, not a single patient that I have treated in the University Hospital or in private practice has died, but all have recovered. In every case the membrane was dissolved, by painting it with papain about five times a day. In very severe cases, I have continued the application during the second day. I found that as soon as the membranes were dissolved the fever disappeared, and the pulse became normal. Dr. Rossbach, Professor of the University of Jena, a very distinguished physician, has had the same results. It is evident that the danger of diphtheria is due to the membrane, and if this is destroyed the danger disappears. As papain can be applied with salicylic acid, which increases its action, I maintain that there is no other drug in existence that has equal properties for this purpose. When using papain to paint the membranes caused by diphtheria, I mix 0.2 grammes* of papain in 2 grammes of water; this is sufficient for application. I never mix more than the quantity of papain required for the one operation, as it appears that papain loses somewhat of its power if allowed to dissolve for any length of time in water. Therefore after three hours I prepare a fresh solution for application. Papain cannot harm either the stomach or bowels. I have taken it myself in doses, 0.1 to 0.2 gramme (1½ to 3 grains), I have prescribed papain to a great many of my patients affected with disease of the stomach, but I have never known any bad effects. Even an atonic and also an anæmic stomach can take it without the slightest ill-effects. On the contrary, an increased appetite is soon observed. Papain dissolves the mucus and cleanses the stomach effectually. It is not correct that papain dissolves the lining (mucous membrane) of the stomach. I have given it to animals, and have observed, after having the animals killed, that the mucous lining of their stomach was sometimes slightly reddened. If, however, papain is given directly after meals, when the stomach contains food, I have never noticed a change in the appearance of the stomach. Acidity of the saliva is in most cases a consequence of deranged digestion of the stomach;

* 7½ grains to a gramme.

by taking papain, which causes an increase of the powers of digestion, the acidity of the saliva will cease.

* *

THE following difference between the action of papain and papain is important to note:—With or accompanying the acidity of the saliva, there is an excess of acidity in the stomach. This can be removed by prescribing *Natron bi-carbonicum* (bicarbonate of soda), &c., but as soon as the acid in the stomach is thereby decreased, the effect of papain is paralysed, because papain only acts when it comes in contact with a free acid. As, however, papain digests either with an acid or alkaline reaction although best in pure water, it is clear that papain will decrease any acidity of the stomach or saliva, and promote a good digestion. This is an important point to bear constantly in mind. "I consider it a most remarkable circumstance that meat soaked in papain and water, or even moistened over with it, will not putrify (rot), but can be kept for days in a room without further care, to keep it from going bad. On the other hand, meat moistened with water, without any admixture of papain, and kept in the same room will rapidly decompose."

We may add to this that we have only the last day or two ourselves seen letters recounting the beneficial effects of 30 gr. doses of papain taken three times a day with meals, in cases of torpid liver and stomach derangement, and also of another very interesting case of a planter who was living at a great distance from medical aid, and suffering terribly from derangement of the digestive organs. He was completely cured from taking, with his food, a tea-spoonful of the fresh juice of the papau.

* *

ACCORDING to the *Central Blatt for Textil Industrie*, the industrial energy now being developed in Brazil is accompanied by various projects of interest to China-grass consumers. A concession has been granted to a German resident, by which various rights as to the treatment of the fibre are secured to him for a lengthened period. The researches of various scientific authorities have resulted in the climatic advantages of Brazil being fully established with reference to China-grass cultivation. The hope is expressed that the German mercantile community will unite in this object by forming an association, and thus acquiring a position compensating them for that which North America has gained by the prospective arrangements for growing China grass in the Southern States.

* *

THE interest taken by Australian capitalists in the development of the territory held by the British North Borneo Company is well worth the notice of the public. Several joint stock companies have been floated with great success in the colonies for the purpose, especially in connection with sugar. Mr. de Lissar, an agent of one of them, a short while ago, paid a visit to Melbourne from Sandaka, and on being interviewed on board the steamer at Brisbane by the editor of the *Australian Tropical Planter*, he gave a few facts connected with the capabilities and resources of North Borneo. He says that there can be no doubt that the island is as fertile as New Guinea and as prolific as Ceylon. The soil and climate are highly suitable for cane, labour is more than abundant, everything is done by the contract system. The Government is under Imperial supervision, and, therefore, law and order is perfect. Labour consists of all kinds of Asiatics, and in a short time cheap cane-sugar from Borneo will be seen in Melbourne. Tropical culture of every kind flourishes, and the cane crop averages from 50 to 80 tons of cane per acre. The growth of cane in the nursery is sometimes astonishing in height and weight, and it is thought they should yield over 4½ tons of sugar per acre at the very least. If so, this is up to the Hawaiian production, and to the best Tweed, Johnstone, and Burdekin plantations. During M. de Lissar's visit to Melbourne his syndicate arranged to purchase a gigantic mill recently erected in Oochin China, which was found too large to work profitably in that country. It was made by Manlove, Alliott, Fryer & Co., and is said to be the largest sugar mill in the world.

* *

A new plan of growing wheat has been tried at the Cawapore Experimental Farm. It consists in dividing the field into

strips, alternately raised and depressed. The crop is planted on the raised strip; and the depressed strips, during the growth of the crops, are constantly cultivated. In the following year, of course, the strips change places, and the inventor claims that, by this means, full crops of wheat could be grown year after year on the same field without manure. This view is challenged by English agriculturists, who are of opinion that the soil would become, in time, greatly impoverished, owing to the active nitrification set up by the constant tillage, and the loss again of nitrates so formed, by drainage, not to mention the extra labour of constant ploughing. The experiment at Cawnpore gave but a modified success. The crops sown on the higher ridges were exposed to the wind, and were thrashed out by it just when the grain was ripe. The actual outturn of the area under crop, however, was very high, equal indeed to the highest yield obtained by liberal manuring elsewhere; a result which does not seem necessarily due to the system of cultivation, which, except for the crop being in higher ground, was that usually followed. Moreover, the area left uncultivated—in this case two-thirds—has to be taken into account in estimating the outturn per acre. It is proposed to utilise the intermediate spaces by growing a leguminous crop, which, as is well-known, has a beneficial effect on the soil by its power of concentrating and retaining nitrates in it. Major Pitcher in this connection indulges in a natural regret that such great issues, as are involved in these experiments, should hang on a stray field in Cawnpore; and that there are not in India, as in America, hundreds of farmers ready to test, fully and practically, any such idea that presents any glimmer of progress, accepting cheerfully, as inevitable, the axiom, that in experimental work, there must be as much disappointment as success. We fear the day is yet far distant when this will be the case in India. Even in England, Mr. Mechi was looked upon as a visionary theorist, and for years stood alone as an experimental farmer. Possibly the proposals of the North-West Provinces' Director of Agriculture, Mr. Smeaton, for enlisting the co-operation of zemindars, as Honorary Assistant Directors, may arouse some interest in such matters, even at the cost of a little self-sacrifice.

.

THE report on the prospects of the rice-crop in British Burmah, for the month of January, is as follows:—"All the crops have now been reaped, and a large proportion of them threshed. The result of the enquiries made by the district officers, amongst the cultivators, is that the crop of the present year in most districts has given an average yield; the estimate of a twelve-anna crop over the whole province is, therefore, maintained, and the exportable surplus is estimated at 975,000 tons."

.

It is an acknowledged fact that the production of cotton and its consumption go on side by side, and all cotton produced disappears without any great effort to get rid of them. What is more, it is quite apparent that with the increase in the demand (growing up every day, it will, in the next few years, be fifty per cent more than it is now. In connection with this subject, the following statistics prepared by Mr. W. J. Basilié, who has devoted a long series of years to the study of it, will show the colossal magnitude which the trade has assumed from small beginnings. The total production of cotton last year amounted to 9,401,000 bales. The quantity consumed may be thus approximately reckoned—America, 2,238,000 bales; England, 3,866,000 bales; European continent, 3,120,000 bales. The consumption of cotton by Indian spinners may be left out of consideration. All the cotton produced went into consumption with the exception of a trifling balance of about 386,000 bales; and, as the records of previous years show similar results, the first portion of the theory advanced may be assumed to be correct. Now, let the figures be analyzed so that data may be obtained as to the probable future consumption of cotton. The consumption of cotton in England for cotton goods exported is 2,534,760 bales, and the consumption of cotton goods in Great Britain is 1,131,240 bales, the latter quantity being equal to 12 pounds of cotton per annum for each person. The consumption of cotton goods sent from England to the East Indies average

annually 1,737,000,000 yards, equal to 1½ lbs. of cotton per head; and to China and Japan 442,000,000 yards, or 4 ounces of cotton per head. The consumption of cotton in Europe for cotton goods imported is 620,000 bales, and the cotton consumed on that continent for cotton goods there manufactured is 2,500,000 bales, equal to 6 pounds of cotton per head. The consumption of cotton in the United States for cotton goods exported is 1,403,000 bales, and the cotton consumed for cotton goods manufactured for home use is 835,000 bales, equal to 6 pounds per head. Taking past experience into consideration in conjunction with last year's consumption, it is under-estimating future consumption to assume that within the next three years, the requirements of the East Indies, China and Japan will rise to 2½ pounds of cotton per head, which will give an increase of 2,478,200 bales. It has already been said that the consumption of cotton in Great Britain is 12 pounds per head per annum, and on the Continent 6 pounds per head per annum.

Ignore any increase in the consumption of Great Britain, but allow the European consumption to increase from 6 pounds to 8 pounds per head, which is a moderate computation, seeing how the consumption has grown during the last decade, and in two or three years there will be from Europe alone an increased demand for cotton amounting to 1,250,000 bales. Then allow an increase in the American consumption to bring up its total to 2,613,000 bales, and the result is that within a year or two or it may at the outside be three years, there will be required by cloth manufacturers 13,127,200 bales of cotton for the year's work, and it requires no stretch of the imagination to see that in five years' time 15,000,000 bales will be required for manufacturing purposes.

.

THE Chief Engineer, Government of Madras, in submitting a statement of traffic on the Godavari and Kistna Delta Canals, and on the Dumagudlem, Buckingham and Kurnool Canals, for the half-year ended on 30th September 1884, remarks that the amount of tolls and license fees collected from boats registered for traffic in the Godavari Delta canals, was Rs. 42,377 more, while the amounts collected from boats registered for traffic on the Kistna Delta Canals and on the Buckingham Canal were, respectively, Rs. 5,107 and Rs. 7,897 less than those collected during the corresponding period of the previous year, the variations being due to the introduction of the revised rules for navigation, under which a single license, issued for the official instead of for the calendar year, entitles a boat to ply on all the canals. The large increase in the tonnage of boats on the Godavari Delta Canals seems to be due to the carrying capacity of the boats being, under the revised rules, calculated at 50 instead of at 75 cubic feet a ton. In the Godavari Western and Kistna Eastern divisions, the last column of the statement for the half-year ending 30th September 1883, has been left blank, as the statistics were not properly registered during that half-year.

.

MR. W. WILSON, Director of Revenue Settlement and Agriculture, Madras, has submitted a statement showing the distribution of 20 maunds of Nankin cotton seed received from the North-Western Provinces in June last year. On the question of the encouragement of the growth of Nankin cotton and of the manufacture in jails for military purposes of cloth woven therefrom, he refers to the letter addressed by Messrs. Binny and Co., to the Government of Madras, on the subject. It is perfectly clear that there is in this presidency private enterprise which is perfectly able and willing to manufacture cloth from Nankin cotton that would be suitable for army purposes, if only the raw material can be procured. Messrs. Binny and Co. whose terms are moderate offer Rs. 15 a candy less than the price guaranteed by the Government of India to producers of cotton grown from seed distributed through Government agency; but now that there are buyers in the market, the question comes whether the competing guarantee of the Government of India should not be withdrawn. The guarantee was given in view principally to the encouragement of the growth of this particular variety of cotton, but if there be established a sure and certain demand for it for military or other purposes, no guarantee of price by Government for the raw material will be necessary to ensure the growth of as much as the market may

require. From the letter of the Superintendent of Army Clothing, it appears that the quantity of cloth required for a sepoy's uniform suit is about 8½ yards. At Messrs. Binny and Co's price of As. 4-3 a yard in Madras, which is only 3 pies a yard higher than the price that the Government of India propose to issue, the cloth manufactured at Buxar central jail for a sepoy's suit would cost in material Rs. 2-4½, that is, As. 11½ less than the Rs. 3 value of the free issue of material, to which under the regulations the sepoy is entitled. The cost of the material for a suit issued by Government from Buxar jail at the cost of the raw material is Rs. 2-2½, or 2½ annas less per suit than Messrs. Binny and Co's price. The Government of Madras in a recent Resolution says that the question whether the Government of India guarantee of four annas per pound for cleaned Nankin cotton should be withdrawn, need not now be considered; when the cotton comes into the market, if it is found the guarantee interferes with private enterprise, it will no doubt be then withdrawn.

.

A MEETING was recently held of the German coloured paper manufacturers at which Herr Dassauer made a report on unpoisonous colouring matter. The object of the meeting was to aid Government in passing a law which will be acceptable to all. Dr. Prior, of Nuremberg, has made very exhaustive experiments with all the colouring matters used. He believes that the great practical point for the Government to do would be to fix the maximum quantities of poisonous matters used in colouring that are innocuous. He says: "Every chemist knows that it is absolutely impossible in technical business to employ chemically pure raw or half raw materials without enormously increasing the cost of production. Many raw materials contain arsenic, lead, copper, zinc, etc., which, when working them, are incorporated as auxiliary stuffs and half manufactures. It need only be mentioned that English commercial sulphuric acid contains arsenic and lead, and these are at least partially contained in the products made with it. Besides this, every chemist that has an experience with technical chemistry knows how difficult it is to wash out a copious precipitate so as to remove the smallest quantities of the salts that have been dissolved in a liquid. Many precipitates retain a portion so inveterately that it cannot be removed at all. It would be requisite to place certain limits in the matter so as both to give due weight to these technical considerations, and, on the other hand, to protect hygienic interests. The innocuousness of these quantities can be ascertained by reckoning them from one gram of colouring stuff. Then, as under 100 square centimetres of wood can be dyed in water or varnish colours and about 600 square centimetres of paper, one gram of colour therefore, or 100 square centimetres of painted wood, or 600 square centimetres of paper hangings, etc., should contain:

Chloride of barium,	0.0151 gr.	Chloride of zinc,	0.0209 gr.
Carbonate of lead,	0.0025 "	Bichromate of potassium,	0.0036 "
Sulphate of lead,	0.0029 "	Chloride of tin,	0.0160 "
Sugar of lead (acetate),	0.0029 "	Sulphate of copper,	0.0045 "
Sulphate of zinc,	0.0247 "	Arsenical acid,	0.0025 "

Several manufacturers thought the quantities would in any case greatly vary, according to the use of the papers. Dr. Prior's views were adopted.

SILAGE IN INDIA.

II.

It was shown by us in our first article on this subject, that a succession of wet seasons rendering hay-making almost impossible in some localities in England, had recently forced the system of ensilage upon the attention of English agriculturists. It is not a little curious that the introduction of this system into France was brought about by a diametrically opposite cause. In June 1870, there appeared an article in a French journal, in which M. Vilmorin-Andrieux called the attention of French farmers to the process of ensilage; but had it not been for the abnormally dry season of that year which forced its attention upon them, the attempt would probably have remained barren for years. Once introduced and its value observed, the system grew rapidly in popular favour, and has been generally adopted by French agriculturists.

The scarcity of fodder in India during the hot weather and in the rains, and the chronic starvation of the cattle therefrom, have told heavily upon all native breeds of cattle, as is seen in their degenerating in their capacity of yielding milk, as well as in other respects. One of the most important elements in the food of the Indian people is cow milk, and anything which interferes with milk production, either in quantity or quality, is a matter of the greatest moment. Hence it is that the question of ensilage is so important in Indian agriculture, and it is gratifying to hear of an attempt here and there by conferences and meetings to consider the advisability of this method of ensilage in India. Apart from the consideration of the subject by the Commissariat, if its usefulness can but be brought home to the Indian peasantry who as a rule possess a few heads of cattle each, so as to make, by this shift, themselves independent of the sun and rain, and save their cattle during seasons of drought, the system will soon work its own way. What seems to be wanted is a trial for the system upon a scale and under circumstances which should emphasize the verdict obtained from that trial. We are neither advocates for nor antagonists of the system. A series of careful and adequate experiments in the different provinces and districts is what we look for, and our aim is to lay before our readers what is already known on the subject in England, America, and Europe.

The use of silos or pits for the storing, or to preserve uniformity of expression, for the ensilaging of grains, has been successfully practised in India and other Eastern countries for ages, and is still resorted to widely in some form or other. In Europe, the Moors introduced it into Spain, and from the latter country, it found its way into France, where it may even now be seen on a large scale at the stables of the Paris Omnibus Company. The silos which have thus such high historical antecedents, do not however appear to have been used in Europe for the preservation of green fodder before 1861, Herr Reihlen, of Stuttgart, having first drawn attention to the subject in 1862. "It is well-known that in Germany, most large farmers grow extensive areas of sugar-beet, and that the leaves of the plants are used as green fodder in the autumn. The oxen which are to be fattened on beet root pulp during the winter, are employed in the autumn as draught animals, and then require concentrated and very nourishing food. The beet root leaves must, therefore, be used wastefully in autumn, or altogether wasted, unless they can be preserved for mixture with other food in winter. This is the explanation which M. Reihlen gave in 1862 for his first attempt at preserving green food in silos." We have simply quoted what is said by Mr. Jenkins, of the Royal Agricultural Society of London, as to the origin of ensilaging green fodder in Germany. The practice found its way into France in 1870, and since then has been slowly but steadily gaining upon the favour of French agriculturists. The system was brought under the notice of British farmers some years ago, but it is only within the last two or three years that they have attempted to preserve green fodder in silos in England.

We shall now pass on to a study of the subject under the following heads:—

- 1—Construction of silos.
- 2—Filling, and covering silos.
- 3—Opening silos.
- 4—Utilization of silage.
- 5—Chemistry of silage.
- 6—Crops fit for ensilaging.

We shall take each of these headings in order, in our future issues.

INDIAN WHEAT.

A RECENT official memorandum of the Indian wheat harvest of 1884 tells us that the total area under this cereal in the country is about 26,000,000 acres, and that the total yield in a fairly good year, is about 135,000,000 cwt., or 30½ million quarters. This is an average out-turn of 9½ bushels or 5½ cwt. per acre. The average yield in England meanwhile is 30 bushels an acre, in strange contrast with the abnormally low production in India. This remarkable difference leads us to institute a comparison between the chief factors of wheat-growing, in the two countries respectively.

Miscellaneous Items.

As regards soil, it may safely be affirmed, and without fear of contradiction, that India does not suffer by the comparison. It is difficult to realise how an English farmer with a soil sometimes but six inches deep, or hardly that, overlying a hard rocky subsoil, can raise 28 to 30 bushels of wheat an acre. It is evident that the cause of the unusually low average in this country, is not in the character of the soil, but must be sought elsewhere. In the method of cultivation, there seem to be two primary differences between Indian and English agriculture. Although a good deal has been written and said in India on the subject of rotation of crops, the question has never been fully put before the Indian public, in its proper aspect. Reserving a complete consideration of the subject for a future occasion, we may point out that in English agriculture, wheat generally follows clover in rotation, and succeeds best after it. The fact was first ascertained by experience, and has since been scientifically verified, and accounted for. In India no doubt, the ryot practises some sort of rotation for wheat, as it generally follows autumn paddy, locally called *aus*, or jute known in the vernacular as *pat*. But neither *aus* nor *pat* is a crop really suited to prepare the soil for wheat. The valuable property which clover possesses in a high degree, of preparing and enriching the land for the coming wheat crop, has no existence here. The Indian rotation for wheat, so far from benefiting it, not unlikely injures the wheat. For both *aus* and *pat* are exhausting crops, particularly the latter, leaving the soil more *hungry* than before. They would seem to be the very last crops that should be selected to precede wheat in rotation, if it be our aim to benefit the crop by such rotation. Here, then, is an open field for the practical but scientific farmer to try his skill. We want to discover a good rotation for wheat. At present we have none. Where wheat is grown year after year on the same soil as in the Nerbudda Valley, without any rotation at all, the Indian peasant cannot expect to raise crops like those of the English farmer. But in England where this practice of growing wheat year after year upon the land, has had full trial, it has been definitely proved that it can be so grown for a long time, without any sensible falling off either in quantity or quality, so long as the land is periodically and liberally dressed with manure. This is valuable experience acquired for the Indian peasant by the perseverance of the British farmer, and the expenditure of capital, and the principle holds good not only with wheat, but is likely to do so with all the cereal crops grown in India, and used as staple food; and the fact has to be brought home to the Indian peasant, who complains that his land will grow no more wheat, or has become wheat sick. Our ryots require to be taught that the land will grow wheat, if properly cared for. Conservative as they are, it is useless to ask them to depart from their routine methods of cultivation, and to use the droppings from cattle as manure, knowing they can ill-afford to spare them for the purpose; but they can be made to understand that Rs. 2 or Rs. 2½ per bigha laid upon the soil as *nitre* will accomplish the purpose. This sum will buy half-a-mauud of the manure, which mixed with five or six times its weight of ashes of cow-dung, or other fuel, or indeed any powdery matter available, and spread over the young wheat crop as top-dressing, is sure to increase the yield, in nine cases out of ten, to twice if not three times the normal nine bushels an acre or three bushels bigha. If by an expenditure of Rs. 2½ per bigha, an increased yield of 3 bushels or say two and-a-half maunds may be reaped, it means a clear profit of Rs. 2½ per bigha, the wheat being supposed to sell at Rs. 2 per mauud. This almost incredible profit of cent per cent will not surprise the initiated few who take an interest in agricultural questions. The real clue to the marvellous success of English agriculture is mainly, if not wholly, due to the introduction of chemical manures through the admirable and sustained exertions of Sir J. B. Lawes of Rothamsted. The average produce of wheat per acre in England is unparalleled in any other part of the world, and it is chiefly due to the practice of top-dressing with nitrate of soda, or ammonium sulphate—two most useful and valuable manures at the disposal of the British farmers. To come nearer home, the Cawnpore Experimental Farm grew last year 56 bushels of wheat per acre, and the plot which gave the yield was treated almost precisely as we have now suggested. We shall recur to the subject, as it is plainly of the very last importance.

A BOMBAY contemporary hears that the Theatre Royal at Grant-road is to be converted into a flour mill.

In Nebraska, the people are said to be burning corn for fuel, because it is cheaper than coal. The stove is known there as the cornatory.

THE Bengal Government estimates the stocks of rice in and around Calcutta for the first week of February at 19,31,974 maunds, of which 8½ lakhs are available for export.

A TIDAL wave from three to four feet high visited the north coast of Tasmania on the 6th of January, and appears to have done some damage to the shipping in the river Leven, as well as to have washed away a large quantity of timber that was piled on the banks of that river, and of the Emu and Forth rivers, ready for shipment.

FRANCE stands in the sixth place for the production of malt liquors, there being in the country 3,000 breweries, which produce 157,000,000 gallons. England heads the list with 27,000 breweries and 990,000,000 gallons. Then come Germany, the United States, Austria, and Belgium. Below France the order is Holland, Denmark, Sweden, Switzerland, Russia, and Italy.

A CAREFULLY prepared table of the Australian wheat crop of this season shows that the average yield for the colony of Victoria will be about 9½ bushels per acre, and as the total area cultivated is 179,000 acres, this will give a total of 11,441,000 bushels of wheat. After allowing for home consumption and for seed, it is expected that there will be 4,581,000 bushels available for exportation.

THE Government of Madras have authorised the Collectors of the different districts which suffered from the cyclone in December last, to use their discretion in granting remissions of assessment. This will, of course, be a great help to the cultivators, but in addition to this, the Government of India has made a special grant of Rs. 3,75,00 for repairs to minor irrigation works, many of which are also damaged by the floods caused by the storms.

THE latest reports of the condition of the crops throughout the Bombay presidency state that they have been slightly injured by mildew in parts of Nasik, and by frost and blight in parts of Poona. The cotton and tobacco in some parts of Hyderabad in Sind have suffered from frost, and the same crop has been blighted in a few parts of Dharwar and Belgaum. A scarcity of fodder and drinking water still continues in parts of the Southern Mahratta districts.

WITH the failure of the coffee plantations, the Ceylon planters turned their attention, and with much success, to tea, cinchona, and cocoa; and now we see that another product, cardamoms, is proving very remunerative. On one estate of only 50 acres, 12,000 lbs. have already been picked, and it is estimated that before the end of the season the crop will reach 20,000 lbs., in which case, at the present price of cardamoms, the returns would be equal to about £40 an acre.

A CONTEMPORARY hears by wire that at a large and influential meeting held at Bellary lately, it was unanimously resolved to memorialise the Government of Madras, bringing to its notice the present state of distress of the people of the district, who are already emigrating in large numbers in consequence of the failure of the monsoons, and praying that immediate steps be taken to commence the Soongabhadra canal project as the best means of meeting the present and guarding against future distress from famine, which is of periodical recurrence in this district.

THAT harmless, and, as some will say, necessary drug, tobacco, is becoming one of the most valuable friends of the Chancellor of the Exchequer. The "Statistical Abstract" shows that in the year 1881, the latest to which the return relates, the duty on tobacco brought in a revenue of no less than £8,658,947. The sum is nearly one-half of the total yield of the customs duties of the year which brought in altogether £19,210,460. Tobacco has quite superseded wines and spirits in their ancient prerogative as the chief supporters of the national purse. Wines and spirit together brought in during the above year £5,819,826.

IRRIGATION progresses slowly and satisfactorily, if not to any large extent, in the Bombay presidency. The irrigation works are few and far between, except in Sind. Last year the area irrigated was increased by about 4,000 acres, and this is all the more satisfactory as the rainfall of the season was above the average, which shows that even in a good rainy season the ryots are able to appreciate the benefit of permanent irrigation works. Another factor which may have led to the increased demand for water is, that the rate charged has been reduced to four annas an acre, which appears to be so small a rate that Colonel Le Mesurier, the Chief Engineer of the Irrigation Department, says that most of the cultivators could not believe or understand so large a reduction.

THE French steamer *Ville de St. Nazaire*, 1074 tons, Captain G. Benoit, arrived in the Pondicherry Roads a few days ago from Cayenne, Guadeloupe, and Martinique, having on board 244 time-expired and other emigrants. 40 deaths from dysentery occurred during the voyage which took 40 days from Martinique: many of the coolies are of the better class who have served several contracts;

having been employed as maistries and in other superior positions; most of these brought considerable sums of money with them, mostly in gold coins and bills, but a good many others were very poor. Wages for all kinds of Indian labour are still high throughout the French Colonies, especially at Cayenne, where first class estate maistries earn from Rs. 50 to Rs. 60 per mensem; ordinary coolies get from Rs. 18 to 26 per month. There were a good many sick among the coolies landed, who were immediately conveyed to a camp which had been formed for their reception outside the boulevards on the south beach, and placed under medical care.

Selections.

THE AGRICULTURAL RESOURCES OF INDIA.

A PAPER on the above subject was read on January 23rd, before the Society of Arts, London, by Mr. E. C. Buck who is now returning to this country. After alluding to the absence of agricultural statistics concerning India, which would not be remedied until 1886, when the report recommended to be compiled by the Famine Commissioners will be published, Mr. Buck paid a well-earned compliment to Sir John Strachey, for having been first to recognise and insist upon the necessity of such a report. He referred to the substitution of permanent agricultural departments instead of periodical establishments to assess rents only once in twenty or thirty years, as "one of the chief reforms" of Lord Ripon, and exhibited to his audience the first volume of the series comprising the reports which will be published in 1886 as the result of that reform. He then endeavoured, for the better understanding of the subject, to give his audience some ready method of realising the actual extent of India:—

Taking Egypt as the unit, the North-West Provinces, exclusive of Oudh, is for administrative purposes marked off into five large and two small so-called divisions. Now, assuming the population of Egypt to be 5,500,000, and its cultivated area to be 5,500,000 of acres, we find that in cultivated area four out of the five large divisions of the North-West Provinces are each of them equivalent to about four-fifths of the Egypt unit, while the fifth division is an Egypt and a quarter. The statistics of population bring out similar results. Altogether, in cultivated area and population, the North-West Provinces are equivalent to about five Egypts. The little province of Oudh, which is held like a ball in a cup by the North-West Provinces, is as large as an Egypt-and-a-half. Bengal would absorb no less than ten Egypts; and the Punjab three-and-a-half more; Bombay, with Sind about the same; Madras, about eight Egypts. The Central Provinces in population less than two, but in cultivated area more than four, with a possible, if not probable, extension to eight Egypts. British Burmah gives one Egypt, with a possible extension to several more. Assam, of which an Egypt-and-a-half is cultivated now, can be, it is believed, expanded into at least four. Berar, less than an Egypt in population, exceeds it in cultivated area. So far the British provinces. I will not venture into the native States.

Passing next to the climate of India the lecturer asked, "Why should that triangular spit of land which we call India possess such infinitely greater value than the immeasurably more extensive trans-Himalayan regions?" The answer we gave as the one word "Rain." But he explained:—

Although the monsoons of India confer upon it its agricultural rank amongst other countries, yet, within India itself, they vary immensely, and create enormous varieties of climate in combination with two other varying factors; (1) the temperature due to latitude, and (2) dryness due to distance from the seaboard, or to the scantiness of underlying water; the consequence is, that there is no crop in the world which India cannot produce. This is a great advantage.

Dividing the year into four quarters, the south-west monsoon, the monsoon *par excellence*, occurs, he explained, in the third quarter, the south-east monsoon in the fourth, and the north-west in the first. He continued:—

Now it is the combined force of these three monsoons, mechanically assisted by the mountain ranges, that provide the agricultural resources of India, and raise it to an importance which the barren wastes of the huge continent to which it hangs cannot reach. But it is not only in pouring showers and moisture on the crops of each year that the monsoons create the agricultural resources of India; they also wash down, and have forages washed down, in rivers and floods, the fertile soil on which their crops are grown. They also fill vast underground reservoirs with perpetual seas of fresh water lying dormant, too, in the annually renewed reservoirs of mountain-stored water, is an enormously powerful mechanical force, which will some day, be enslaved and controlled by the patient perseverance of our engineers, and will do much to make up for the absence of coal in the northern continent. I now wish to lay very great stress indeed upon one point. Although the monsoons confer all this agricultural wealth, the uncertain character of the rain, in the greater part of India, is so excessive, that the agricultural outturn, so far as it depends on the rainfall of the year, oscillates violently. How to overcome this oscillation, or to mitigate its effects, is the great problem which has to be solved, and it is, I am glad to say, being vigorously attacked, and to some extent solved in India.

Unfortunately it is in the areas of uncertain rainfall, which are the battlefields where a continual fight between death-dealing desiccation and life-bestowing moisture is carried on, that the largest populations are often found, and it is only by bringing to their aid every means of assistance (not irrigation alone) to enable them to overcome or mitigate the effects of desiccation, that the

agricultural outturn of the Empire can be most materially increased. Before indicating these means, I will try to give some little idea of the area of uncertain rainfall.

Eastern Bengal, Assam, Burmah, the Central Provinces, and a strip of Madras, Mr. Buck then enumerated as the districts which have enough rain to produce crops sufficient for the maintenance of the cultivator and the payment of his rent. The part of India on the other hand where the monsoon is often insufficient—denominated by Mr. Buck the "shrinkage area"—he described as a vast belt "which stretches like a rash from the Punjab through the North-West Provinces and Rajputana, and then tying itself in a knot on the south-west edge of the Central Provinces, drops in a wide and ragged band through the Deccan, Mysore, and Western Madras." The "rash" part being the area not reached by a weak monsoon, and the hanging band, the "rain shadow" of the Western Ghats which intercepted the rain-clouds. He then continued:—

Owing partly to historical cause, and partly to the fearful struggle that has to be carried on with nature in many parts of India, the Indian cultivators have, as a rule, developed into the most patient, hard-working, and, in many cases, skillful agriculturists that can be found on the face of the earth. Inured to privation, accustomed to maintaining life on short meals, and with scanty clothing they give their labour for the smallest return it is possible to conceive. The consequence is that, broadly speaking, the agriculture of the country is carried on by a vast human machine, a machine of flesh and blood which is cheaper in its working than it is possible for any machine of steam and iron to be. I have just met a Public Works official who went from India to America to look at the agricultural machines in that country. Nothing, he said, struck him more than the way in which machines diminished in size and frequency as he passed from a region of high wages to a region of low wages. In India we come down to a region where the wage-level is so low that the multiplied power of human muscles, or the multiplied power of very weak cattle, supercedes all but machinery of the very lowest order. Wages are rising, and will continue, with civilising influences, to rise still more; but until they do, the question of increasing the products of the country by the application of machinery must be considered a secondary one. The first and primary question is, how far it may be possible for the Government to increase the effective working power of the two flesh-and-blood machines, the men and their cattle—and thus fulfil a duty which a feeling of humanity as well as a desire to develop agricultural wealth, imposes upon it. The system of agriculture is, as you know, eminently one of *petite culture*. I shall be exaggerating very little if I say that the country is split up into so many millions of five-acre farms. The holders of these farms are small tenants, paying rent over a large part of India direct to the State, and over a still larger part to a landlord, or a landlord intermediate between them and the State. As a rule the cultivator will do anything that is necessary within the boundaries of his own five acres; it is a delicate matter to meddle with him there.

But outside his five acres he can do nothing; and as (with due regard to certain bright exceptions) the intermediate proprietor avoids doing anything, it devolves upon the Government to take whatever measures may be possible and expedient, (1) to prevent the deterioration of the working power of the agricultural machine, and (2) to improve its working power. Five years ago, England sent a message to India that the people must not be allowed to die of starvation. But Sir James Caird and General Strachey, who bore that message, found that much more was necessary than to provide the starving people with food when famine was on them. It was necessary, they found, to secure to them a normal condition of strength and health; and the consequence was that the exhaustive report, written when the labours of the Famine Commissioners were concluded, by their able secretary (Mr. C. A. Elliott) suggested administrative reforms of all kinds, which, at first sight, had little to do with the question of famine, but which, on examination, were found to have very much to do with it indeed. For the whole country being built up as it were of those five-acre bricks, it is found that all administrative problems, however intricate, can be resolved into factors in which the five-acre unit and the prosperity of the five-acre holder is the most important one of all. The net result of the Famine Commissioners' mission was a further message to India from her Majesty's Secretary of State, inviting closer inquiry into vital and economic facts, and the adoption of measures tending to increase the produce of the country as well as to cope with famine.

After quoting the words in which Lord Ripon gave this message to the country, Mr. Buck proceeded:—

I will indicate briefly the directions in which the State, or landlord-in-chief, is taking measures for the maintenance of the full working power, as well as for the increased efficiency of the great muscular machine. They are these:—The promotion of railways; of canal irrigation, and of well irrigation; the improvement of the revenue and rent systems; the reclamation of waste lands, with the establishment of fuel and fodder reserves; the introduction of agricultural improvements; and finally, emigration. Railways, with few exceptions, tend to ameliorate the condition of the cultivator mainly in two ways. Firstly, they ensure him a better average price for his produce when he has a surplus for export; secondly, they bring him food at a cheaper price when he has insufficient for subsistence. On the one hand, his average receipts are greater, and on the other, his average cost of living less. But there are two questions which have, within the last year or two, cropped up in connexion with the effect of railways on food, with respect to which I should like to say a word or two. One is the position of a remote tract, in which corn is said to be raised at a very small cost, and which is assumed to be worth tapping because the price is low. But is it not the case that the price is simply low because the corn cannot get away to a market, and that the cost of it is small because the wages are calculated in terms of the corn?

which, as matters stand, has little or no value? But bring a railway to a tract like that, and the price of the exportable surplus will at once rise to the market value, and with it the price of labour by the conversion of the wages into cash at the new money rate. Is not then the real benefit of the new railways to give to the cultivator of that tract a more substantial return for his surplus, and supply that surplus at a cheaper rate than it would otherwise be carried to a distant point on the railway where there is no surplus, or to a port? The other question is this: A fear has been expressed—I am not sure that an assertion has not been made—that railways, by facilitating the export of wheat, injure the country, because they deprive it of a part of its food supply, and that the population of India being already under-fed, should not be allowed to lose a single pound of food. What it would appear right to do is to analyse the wheat exporting tracts, one by one, and ascertain whether the wheat has deprived the agricultural population of any one tract of any portion of its food supply. Such an analysis is being made, and so far as it goes, it shows that the export wheat has not deprived the agricultural population of the exporting province of a single pound of food, but has, on the other hand, enriched them by an increase of about 50 per cent in the value of the produce exported. On the whole, the expenditure of capital on railways, does, by providing the cultivators of precarious tracts with cheaper food when their harvests are insufficient, afford a quicker benefit to a greater number than irrigation or any other measure Government can undertake, and rightly heads the list. The next means of aiding the cultivator in his fight against the desiccation caused by the caprices of the monsoon of the year, is irrigation by canals and wells, i.e., by the utilisation of water stored up by monsoons of previous seasons in the mountain ranges, and in underground seas. A very great deal has yet to be done to make these stores further available notwithstanding the magnificent labours of our engineers. When the Famine Report was written out of about 200,000,000 acres of cultivated land in British India, only 8,000,000 acres were watered by irrigation works, and 12,000,000 acres by wells. All I can say is that every nerve is being strained by our Public Works Department to develop canal irrigation; and next year we shall be able to show you maps of what has been done, and can still be done. Many people have an idea that canal irrigation injures land. The idea is a dangerous one, because it contains half the truth. Water freely applied stimulates production so enormously that the soil becomes temporarily exhausted, and the produce is sometimes for a series of years less than it was before in an average year. But the certainty of a harvest gradually attracts a population. The manure supply and cattle increase, and the ultimate produce becomes much greater than at first. I believe the best safeguard against the intermediate exhaustion of which I have spoken, is to charge a full price for canal water, and thus prevent its wasteful use. Be this as it may, it is impossible to over-estimate the utility of canals in securing certainty of production in every tract in Northern India where the underground freshwater sea is too far from the surface to be cheaply tapped. The present policy is to confine, as far as possible, the expenditure of capital to such tracts. For where the water is near enough to the surface, say on the right side of 50 feet, the agriculturists can build themselves wells, and, as a rule, they build them more cheaply than Government, and only want advances and freedom from excessive taxation of the water as an encouragement to construct them. This encouragement is now being given; and after a long series of experiments, conducted by the officer of the Public Works Department, before mentioned, and whom I now see here to-night (Mr. Wilson), it seems proved that the best direction in which Government can offer positive aid is in employing boring tools to ascertain, by a cheap trial, the character of soils and water in doubtful tracts, i.e., in tracts (very extensive and numerous) in which the cultivator is afraid to undergo the costly experiment of sinking a well through unknown strata, without being sure of results. On the whole, I believe that the irrigation of India may be increased ten-fold over the area of uncertain rainfall, and that the produce may be doubled on the irrigated area.

Mr. Buck then proceeded to advocate the growth of fodder trees and bushes, and the conversion of wastes, i.e., culturable land as yet uncultivated, into pastures to improve the half-starved weak breeds of Indian cattle which he compared very unfavourably with those of Egypt. Goats which are more than anything else to blame for the absence of pasture in India, must be kept strictly off such land. He next referred to the experiment being made by Mr. Wilson among others, for the reclamation of the alkali-wastes into good pasturage lands, for "when once the alkali is mastered it becomes a useful manure instead of a hurtful poison." Withly refraining from more than a mere glance at the "improvement of the rent system," the lecturer then turned to a subject which he said had never received sufficient attention, the emigration of coolie-labour to the "equatorial sea-girt lands" of Borneo, Java, North Australia, parts of Africa, &c. The encouragement of coolies to emigrate, Mr. Buck strongly recommended for three reasons. In the first place the wages thus earned enabled the coolie on his return to his own five-acre farm, to farm it properly; secondly, young men were only thus enabled to amass capital sufficient to purchase farms, and, thirdly, if India neglects at once to occupy these splendid markets for her labour they will be filled by China. With respect to the introduction of agricultural machinery to supersede manual labour, Mr. Buck did not anticipate that much could be done quickly. He said:—

The only machine which has met with unqualified success in reaping a machine of the country, is a small portable sugar-mill with iron rollers, that can be carried by two men, and worked by one weak bullock, which is replacing the wood or stone pestle and mortar, in which natives have hitherto pounded their cane. It is now sold by thousands. But the machine was

not brought to its present state of perfection without years of patient trial and experiment, although its inventors, Messrs. Mylne and Thompson, planters of Bengal, were thoroughly conversant with the local agriculture. This fact indicates, firstly, that the improvement of native machinery can only be worked out by experts on the spot; secondly, that the natives will not, when they are convinced that a machine is profitable, refuse to take it. These conclusions justify the continuance of steady perseverance in experiments by local experts, but does not encourage the transmission from Europe and America to India of expensive machines, which have not been modified by competent experts, so as to suit the conditions of the country.

In conclusion, the lecturer once more reminded his hearers that—

The best, if not the only way of keeping the cultivators out of the capitalists' hands, and of giving an industrious farmer the chance of being his own banker, is to eliminate, as far as possible, the uncertainty which now attends his harvests. The efforts of Government in this direction received an important and effectual impetus from the mission sent out by the people of England, of which Sir James Caird and General Strachey were the leaders. Much, very much, remains yet to be done. But though the work of protection is far from being accomplished, rest assured of this, that whatever pictures may be drawn of local distress in some parts of India, in the greater part of the Empire the condition of the cultivators is materially better than it was fifty years ago.—*Pioneer.*

FIFE FARMERS' CLUB ON THE COMPARATIVE VALUE OF MANURES.

At the fourth quarterly meeting of this club, held in the Royal Hotel, Cupar—Mr. Watt, Kilmany, in the chair—Mr. Mitchell, Fliskmills, read a lengthy and interesting paper regarding the experiments made at several stations with artificial manures. At the outset he dwelt on facts and figures, chiefly gathered from the reports of the Aberdeen Agricultural Association, under whose auspices a large number of experiments were conducted by Mr. Jamieson, with the view of testing the value of various chemical manures. In summarising, Mr. Mitchell stated that 1,644 experiments had been made with different chemical manures in Scotland, principally in Aberdeenshire, and 128 in England. The experiments in England did not afford the same proof of the efficacy of phosphates by themselves, as was the case in Scotland; but when nitrogen was applied along with the phosphates, rapid growth and a heavy crop was the result. Mr. Jamieson says, these experiments have demonstrated (1) that the turnip plant can no more grow without phosphorus than without water or air; and (2) that it must have the phosphorus given to it in an unharmed form (that is to say, it must be neutralised by oxygen and lime, or a substance similar to lime; this triple compound is termed a phosphate; (3) a full crop of turnips (say 30 tons—equal to 67,200 lbs.) contains only about 30 lbs. of phosphorus; (4) bone is an effective manure, mainly on account of the phosphorus that it contains; (5) the more thorough the pulverisation by grinding (or "finer the division") of bone, the earlier the action on the plant; (6) undissolved phosphate, in finely ground coprolite, acts almost identically with phosphate in crushed bone, that is to say, the action is slow, but lasting, and the crop is healthy; (7) dissolved phosphate acts more quickly than undissolved phosphate, and gives usually a rather heavier crop, but a less healthy one; (8) too quick action, resulting in rapid early growth, tends to produce ultimate disease in the plant; (9) steamed bone flour possesses nearly the same rapid action as the dissolved manures, combined with the healthy and lasting action of the undissolved manures, and produced heavier crops than either, allowing for its nitrogen; each pound of phosphorus in steamed bone flour can be got for about 6d. Mr. Mitchell then proceeded to consider the question whether dissolved or undissolved "finger-and-ton," and after reading from Mr. Jamieson's report, he said it will be seen that in every comparison the evidence against dissolved manures becomes stronger. In 1881, where the manures were all vitriolated, the diseased turnips amounted in one group to 1,566, and they ranged from that number to 1,129. Where the manures were of a varied sort the numbers ranged from 576 to 925. Where there was no vitriolising they ranged from 78 to 383. It was some years since a shrewd observant neighbour remarked to him that he was sure superphosphate and dissolved bones produced "finger-and-ton;" and Mr. Jamieson, by these experiments, had proved that idea to be thoroughly correct so that in any soil likely to produce diseased turnips, or where the disease has formerly appeared, it would not be prudent to use a vitriolated manure. In regard to the solid nourishing matter in turnips, Mr. Jamieson's report stated that we were accustomed to attach not a little importance to the fact of a manure increasing a crop of turnips by a few tons per acre; but it was necessary to reflect that in 100 parts of turnip 90 parts were water, and that the proportion of water ran up and down from 88 to 93 parts, and that a crop of 20 tons, containing 93 per cent of water, was only equal to one of 11 tons 13 cwt. as compared with one of 88. In 1876 it was found that nitrogen-manured turnips contained more water, and hence a smaller proportion of solids, than turnips grown without nitrogen. In 1877 this was confirmed, but not uniformly. In 1878 it could not be said that nitrogen had increased the proportion of water. In regard to the effect of soluble phosphates, he found:—In 1876 crop, soluble gave more solids than insoluble. In 1877 the result was in the opposite direction—a bad season, however. In 1878, soluble gave more solids than insoluble. The final average of 200 experiments showed that there were 997 per cent solids after soluble phosphates, and 972 after insoluble—a difference of 0.25 per cent, or equal to $\frac{1}{4}$ ton of turnips on a 20-ton crop. Nitrogen, on the other hand, appears, except in a backward season, to reduce the solids by about 0.87, which would be equal to 2 tons less on a 20-ton crop. Mr. Mitchell

then quoted the results of experiments as to the effect of nitrogen, slightly differing from some of Mr. Jamieson's remarks. He (Mr. M.) had, in some seasons when it was cold in June, seen several fields manured without sufficient stimulus, and had to be sown and re-sown, and the braird did not come away, or did not thrive, till the middle of July. He found that they got a great increase by the application of nitrogen, and the increase was not all water. He came therefore to the conclusion that if they wished to grow a full crop, nitrogen in some proportion must form one of the ingredients of the manure. The speaker next took up the subject of the best manures for cereals, as illustrated by Mr. Jamieson's experiments. The general results were—(1) Phosphate of alumina has exerted little or no influence on crops; (2) phosphates of lime alone have increased the crop from 13 to 28 per cent; (3) phosphates of lime and nitrogen have increased the crop from 38 to 73 per cent. As to the different forms of phosphate of lime, it was found that between the mineral and animal forms there is no material difference; between the insoluble and soluble forms there is a difference in favour of soluble—10 to 15 per cent; nitrogen, alone with different forms of phosphates, nitrogen, and insoluble phosphates, increased the crop 47 per cent, or 32 per cent extra by nitrogen; nitrogen and soluble phosphate increased the crop 66 per cent, or 38 per cent extra by nitrogen. As to the different forms of nitrogen, it was found that nitrate of soda, sulphate of ammonia, guano, and bones have given nearly equal results, except that with insoluble phosphates, guano is rather highest, containing as it does some soluble phosphates, and that with insoluble phosphates, nitrate of soda is lowest. This peculiar result, which has been found in turnips yearly, is now distinctly confirmed by a more nitrogenous plant, viz., that nitrate of soda does not act well with insoluble phosphate. It seems probable that in the case of soluble phosphate, its sulphate acid liberates nitric acid, which probably forms nitrate of lime. In the case of the insoluble phosphate no decomposing or vivifying influence is exerted by the nitrate of soda. As to the influence of various manures on the weight per bushel, the increase in this respect seems to go along with the application of phosphates, and especially finely divided and soluble phosphate, but not always uniformly, and the differences are slight. The same results were shown at Pumpherton and Harelaw. Dr. Aitken states in his report that it is evident from the crops obtained on these plots, that to use potash salts alone, or phosphates alone on Pumpherton, is to bury money, much of which may never be found again. Even when we apply the two together, as shown on plot 17, the crop is a failure. He says how different is the result obtained by the application of nitrogen. Lastly, when all these are combined, and a manure containing nitrogen, potash, and phosphate is applied, the best results are obtained, both in the quantity of grain and straw. The same results have followed the application of nitrogen in the growth of barley. The application of nitrogen and phosphates has held good in the continuous growth of wheat on the same land at Rothamstead. Mr. Mitchell concluded by reading an extract from an essay by Dr. A. P. Aitken, chemist to the Highland Society, confirming the views he had expounded. The Chairman, having complimented Mr. Mitchell on his able and exhaustive paper, invited discussion.

Mr. Russell, Luthrie, said he used to employ dissolved bones on his light cherty land. He had a very nice braird of turnip, and got them well singled, but they all went with disease. He was now in the practice of using drill bone or bone-meal, and semi-dissolving it with liquid manure, and he found he had now cured the disease—(hear, hear).

Mr. Ballingall, Dunbog, said he had listened to Mr. Mitchell's paper with great pleasure; and was gratified to find that the results which had been obtained by competent chemical authorities, such as Dr. Aitken and Mr. Jamieson, corresponded so closely to those at which he had himself arrived. They all knew that they could not grow turnips well where the land was not well manured with phosphates, or ammonia, or nitrogen. Some years ago, when bone flour and phosphates were as cheap as they are now, he was in the habit of using them, along with Peruvian guano (which has since become old-fashioned and gone out of the market) as the principal part of his application, and he was glad to find that practice had been so remarkably confirmed by the results of frequent experiments. As to the grain crops, he believed they all agreed that a large part of the manures applied should be ammoniacal. He thought, however, that the best way was to apply these manures well to the turnip crop, and let the grain crop in a great measure take its own chance. If that were done he did not think the cereal crops would require much assistance from artificial manures—(hear, hear). In listening to Mr. Mitchell's conclusion, the first thing that occurred to him was that it would be a very fitting outcome of the paper if it resulted in the formation of some kind of association by which young men—enthusiastic young men—would be induced to devote a portion of their time to the experiments suggested. Were the association conducted on proper principles, they might secure the personal assistance of some such competent chemist as Dr. Aitken, who was so much engaged in these researches, and they might be enabled to make experiments for themselves, which need not be on either an extensive or an expensive scale. By giving a little special attention to these experiments, and comparing notes from year to year, they might arrive at results which would be of great benefit to them all—(applause).

Mr. Carwell, Rathillet, quite agreed with Mr. Ballingall as to the benefits which might be derived from the experiments he had suggested. In carrying out these experiments, he was sure all the members of the Farmers' Club would be glad to lend their assistance. As each district had its own peculiarities, they might find the results brought out very different from those arrived at by Mr. Jamieson, for it was not at all improbable that what might be advantageous in some districts might be the reverse in others. There was one manure which he thought should receive more attention, viz., potash or sulphate of potash. That was a

manure that was of great service in all crops, especially in the case of light land. He thought that an ammoniacal manure was also of service in bringing away turnips rapidly, and carrying them safely through that dangerous time when they were so liable to the attacks of flies. Looking to the different conditions in which phosphates were used, he thought that soluble phosphates should be used in strong clay soil, and that on lighter soils bone-meal or coprolite might have a very good effect.

Mr. Dingwall, Romorne, concurred in Mr. Ballingall and Mr. Carwell's remarks as to doing what they could in the way of experiments. Instead, however, of having any association specially formed for the purpose, he thought the experiments should be carried out directly in connection with the club—(hear, hear). It would be an excellent stimulus for the club to have work of that kind to carry on, and the experience acquired might lead to very important results. A good many years ago he was in the habit of making some of these experiments himself, and there was one point he would like to see more earnestly enforced—and that was the most suitable time for using ammoniacal or phosphatic manures for turnips. His experience was that ammoniacal manures should be used for early turnips, and phosphatic for the later ones. The year in which he made his experiments there was a very bad braird, and the results—if he had attempted to follow them—would have been very misleading. There was one point, however, which he could not help remarking, and that was that where ammoniacal manures were used, a very large proportion of the turnips dropped off before the end of the year. They simply rotted and were unfit for use. He therefore thought that their experiments, to be of any use, should extend over a good number of years.

Mr. Mitchell, in replying, suggested that some of the young men connected with the club should go up to Rothamstead and examine the experiments there.

Mr. Thom, Leden Urquhart, moved that in order to give practical shape to the suggestions thrown out by Mr. Ballingall, Mr. Dingwall, and Mr. Carwell, the committee of the club be instructed to consider what steps should be taken with the view of establishing an experimental station—(hear, hear).

This was agreed to.

Mr. Dun thought, however, it would be as well to get the experimental station taken up by some landlords, for he believed few of the farmers would hold out long enough to gain more than one year's experience—(great laughter).

Mr. Storrar, Rosbie, did not think that Fife, as a whole, had ever been in the habit of going in largely for expensive manures; but he thought that many of them might still with advantage curtail their manure bill. There was nothing more important than to get a good crop of turnips; but seeing they all depended so much on the climate, it were better to save their money than to lavish it on expensive manures. Considering the low prices at present got for grain, it would be a mistake to use much of light manure. So far as that crop was concerned, their best plan was just to take what Providence sent them—(laughter). He scarcely agreed with trying experiments of their own, and would prefer to get more information from those experiments that were being already conducted.

Mr. Ballingall said it was all very well to get all the information they could, and no doubt the experiments suggested would put them to a little inconvenience and a little cost, but would anything convince them more readily or open their eyes more thoroughly and make them better acquainted with their business than putting their own hands to the matter, and conducting these experiments themselves?—(hear, hear). He by no means thought of having an experimental farm, but they might work in combination on a general principle, and under the advice of some of their members who had some experience in making similar trials. The knowledge thus gained might be of great value to the district—(applause).

Mr. Mitchell said he had overlooked Mr. Carwell's remarks about potash. Magnesia and soda, he should have said, were always necessary. Dr. Aitken had made experiments with these chemicals, and found that a great improvement resulted from the addition of potash.

This concluded the discussion, and the Chairman intimated that in the event of Mr. Tod, Gosspey, not being able to read his paper at next meeting, it would be desirable that some volunteer should be ready to take his place, and should, if possible, give intimation to that effect to the secretary within eight days.—*North British Agriculturist*.

CHEESE AND BUTTER FACTORIES.

[BY PROFESSOR SHELTON.]

A RECENT announcement has been made to the effect that the farmers in the neighbourhood of Rochester have decided to establish a cheese factory, and that, at the meeting held on the 16th instant, when the matter opened and settled, the milk of no fewer than 400 to 500 cows was promised in the room. Rochester is an interesting little market town, pleasantly situated in the beautiful valley of the Dove, a river which for a considerable distance, and until it falls into the Trent, forms the boundary line between Derbyshire and Staffordshire. The town is on rising land, just within the borders of the latter country, and is surrounded by one of the finest dairying districts in the Midlands—perhaps one of the finest in the British Isles. Dove Valley cheese, indeed, was famous in the early part of the current century, the days when local reputation was of more account than it is just now, and when men and their fancies were less cosmopolitan in character than they are to-day: when each dairy of cheese of any consequence went year after year to the same consumers—to consumers who inquired for it at the shops, and when dairymen were seldom unsuccessful in different years and on different farms. Those were the days when farms were

self-supporting, when commercial fertilisers and feeding-stuffs were unknown, and when the herbage on the pastures was in a normal and natural condition. Then, as I have been told by old men who are dead, it was an easy matter to make good cheese almost anywhere, though the yield of it was small.

With the spread of modern farming, the yield of cheese became larger, and the difficulty of making good cheese was correspondingly increased. Yet farmers prospered, and as the years rolled on, farmers' wives were seldom the dairymaids, and hired dairymaids became scarcer in proportion. The difficulty of finding good dairymaids seemed to culminate some fifteen or twenty years ago in the Midland counties, and men who were anxious for the welfare of dairy farming in those counties were casting about for some way or other out of the difficulty. It was admitted that cheese-making was heavy and untidy work, unfit for farmers' wives, as a rule, who had the care of house-keeping and of a family of children on their hands. It was even said, so warm were people in favour of a change, that it was not women's work at all, but should be performed chiefly by the aid of machinery, and on a scale commensurate with the use of modern appliances. At this stage of reasoning, the transition from farm-house to factory cheese-making was easy and simple enough; but though factories were desired in many places, it was found an easier thing to talk about them than to set them going. True, they were as yet untried in England, and no one could foretell with certainty how they would fall in with the special requirements of English dairying; but they had been long in use in America, and were rapidly increasing in number in that country, while the quality of American and Canadian cheese was just as rapidly improving. These were the reasonings which led to the establishment of two factories in Derbyshire, in the spring of 1871, one in the town of Derby, and the other on the estate of the Hon. E. K. W. Coke, at Longford. During the next three or four years, some twelve or fifteen other cheese factories were started in various counties, and then the increase ceased entirely, seeming to prove, in some measure, that the factory system of cheese-making did not supply an adequate solution of the difficult problem which, in modern days, had become developed in British dairying, and which, as I may say, is still in process of solution.

There were, of course, many opponents of the factory system, and its advocates had anything but plain sailing all the time. Others there were who were lukewarm on the subject, on both sides of it: and yet others who, being favourably disposed towards it, preferred to wait the verdict of time and experience. The chief reason, however, why no more than about twenty of these institutions were established is found in the rapid development of the milk trade some half-score years ago—a development, by the way, which, in an intermittent and irregular manner, has been in progress ever since. This new departure in country dairying, providing as it did a fresh outlet for surplus milk, was owing in a great measure to the Food Adulteration Act, and to the stricter regulation of urban and suburban dairies, which led to the disestablishment of a good many of them. As a result of the operation of the said Act, the public had better milk supplied to them, and this promoted a great increase in the consumption of that beneficent fluid. In this way an enormous demand for country milk arose, and the disestablishment of urban dairies had the direct effect of increasing the volume of that demand. The railway companies, too, afforded facilities for the transit to town of country milk, and in this way the latent fluid of scores of rural districts was tapped at its source.

In the *Journal* of the Royal Agricultural Society of England for 1875, Mr. J. C. Morton, one of the ablest of living agricultural writers, contributed an interesting and valuable report 'On Cheese-making in Home Dairies and in Factories,' in which the *pros* and *cons* of the subject are set forth with admirable lucidity. The conclusion arrived at was, on the whole, in favour of factories, though the spirit of the inquiry was perfectly impartial from beginning to end. An interesting footnote to that report runs as follows:—'I understand that on Lord Vernon's Derbyshire estate, although the advantage of the cheese-factory system has been frequently urged upon the tenantry, no application has yet been made to the landlord for the erection of a factory. The fact is that in remodelling the farm building on this estate, the dairy arrangements have been made as perfect as the tenantry can wish. The inference from this footnote is that the farmers, with facilities improved, preferred to make their cheese at home. But this inference is wide of the actual facts of the case, for many of the farmers in that locality—Sudbury, a few miles south of Rochester—instead of making their cheese at home, began to devote, in fact had already begun to devote, their energies to the expanding milk trade.

This they continued to do for some years, until at length, the milk trade being overdone, more or less demoralised by irregularities that had crept into it, they began to cast their eyes in another direction. The milk trade, in fact, was no longer, taken all the year round, a tempting or profitable occupation for the rank and file of the Dove Valley farmers, and the increased scarcity of good dairymaids more than counter-balanced the advantage of perfect dairy arrangements. The difficulty of recommencing cheese-making at home, after an interval devoted to the milk trade, is best understood by those who have tried it. The upshot of all this on Lord Vernon's estate was the erection by the late Lord Vernon, than whom never lived a warmer friend to British agriculture, of a butter factory, to which the surrounding farmers could send their milk. This factory has been in operation a few years doing very well as things go nowadays, and proving a boon to the milk suppliers. The present Lord Vernon takes a warm interest in the improvement of dairy farming, and is ably supplemented by his agent, Mr. Algernon Fawkes. The factory, as I have stated in a previous article, now is lending itself to the tuition of dairymaids, every facility for this object being afforded by Lord Vernon and by those in his employment.

And now, a few miles from Sudbury, and in the same Dove Valley, it has been decided to establish a cheese factory. One was also opened in the spring of the present year at Gratton, in the Bakewell district, in the county of Derby; this, too, for the convenience of farmers who had grown tired of the milk trade, so that the era of cheese factories appears to be entering on a new stage of development, and the milk trade on one of modification. These two industries, identical in their preliminaries, and well designed to supplement and relieve each other, will find a tolerable balance in time, though, as we must admit, cheese-making does not promise to be a very remunerative business for some time to come. There seems to be for the present a better prospect for butter-making in factories, wherever the business is well managed, and the skim-milk can be favourably disposed of. Stock raising, butter factories, cheese factories, and the milk trade there are as bells, so to speak, on which may be rung the changes that give variety and afford profit to the dairy farming of Britain, which, all things considered, is the most attractive of the different branches into which an agricultural industry may be divided.

It is abundantly clear that the old slipshod practices followed so long in dairy farming, and still so very prevalent throughout the land, will not answer our purpose in the future, even as well as they have done in the past, which is not very much after all. The yield of dairy produce on almost any given farm, even on those that have been well managed, has been much smaller on the average during the past seven years than it was in any other seven, I may say, in the last thirty years; this is owing to the wet and almost sunless seasons we have had, and to the reduced fertility of the land. The volume of foreign competition has more than made up the difference, or prices would have been so much higher than they are, as to make amends to some extent for the reduced yields of beef, of milk, of cheese, and of butter. It is to be hoped, indeed, that our yield will improve with better seasons; but there is no prospect of a falling-off in foreign competition. Prices, therefore, are not like to increase very much, and the only way to increase them a little, and even to maintain them where they are, is to produce a better article; and in order to do this, a comprehensive system of dairy education, encouraged by landlords, land agents, and everybody interested in the welfare of our insular agriculture, must spread itself over the face of the country. It will afford me pleasure and satisfaction to contribute my mite, be it never so small, to the improvement which is so greatly to be desired.—*North British Agriculturist.*

MR. JOHN WILSON ON LAYING DOWN LAND TO GRASS.

We are indebted to Mr. John Wilson, formerly of Edlington Mains, now of Wellnase, Duns (whose familiar pen, our readers will be glad to see, is as fluent as ever), for the following:—

Permit me to make a contribution to the discussion now in progress in your columns on the best methods of laying down land to grass, by a narrative of my personal experience in conducting that process. About thirty-five years ago, I resolved to lay down to grass about 11 acres of land at Edlington Hill, as an adjunct to a lambing shed. It is very light, weak soil, with no natural fitness for yielding a good sward of old grass; but was selected for its convenience of situation, for being dry, fairly well sheltered, and having a constant supply of water. It had just then carried a good crop of turnips, which were eaten on by sheep, and was thus clean and in good condition. Being anxious to do things well, I went to considerable expense in providing a mixture of seeds of natural grasses, along with the clovers in ordinary use, and sowed these, about the end of April, without a corn crop. It happened that the weather was dry for several weeks after sowing, so that at first the braird was very partial; but at last rain fell, when the seeds brairded well, and with them an excessive growth of annual weeds, which by and by got so luxuriant that I feared my attempt was to end in failure. At last I set a squad of mowers to work, who cut quite a heavy swathe of this rubbish. I was soon gratified by finding that I had interposed in time to save the seeds from being smothered; for in a short time they came away thick and vigorous, and prospered ever after. When the seeds were sufficiently established to stand it, large quantities of turnips, with cake and corn, were consumed by sheep on this field every spring. Stimulated by this annual manuring, it continued to yield quite a remarkable quantity of good grass down to the end of my tenancy in May 1877.

A few years subsequent to this experiment in sowing grass-seed without a corn crop, I discovered, by what I may call a happy accident, that a valuable forage crop could be taken, not only without harm, but with positive benefit to the seeds. A severe and prolonged snowstorm had rendered it necessary to feed the sheep on the farm of Rawburn in Lammernulr, then occupied by me, so long that by the end of it the store of hay was quite exhausted, and had to be replenished, if possible, before another winter. As it would have caused serious inconvenience to reserve for mowing as much of the grazing land as would have sufficed for this purpose, I resolved to sow tares, to be made into hay, on a 28-acre field, then due in the ordinary rotation to have carried a crop of oats, after turnip, and sown up with small seeds. I used for this purpose the small Königsberg tares, as being less liable than the large Scotch tare to lodge and smother the small seeds. The tares produced a heavy crop, which I had no difficulty in making into hay of excellent quality. When in due time it came to be served out to the hill sheep, they decidedly preferred it to meadow hay, and thrived better on it. I had purposed to mow this tare crop when in full bloom, but a heavy fall of rain so lodged it that I had, for the safety of the seeds, to cut it before it had quite reached this stage. As

it was, the seeds were unharmed, and I never had a more successful take of young grass than on that occasion. This first trial having been so successful, I continued to resort to the same expedient, both at Edington and Rawburn, as often as need required, and with unfailing success. The only change I made was that, always after this first instance, I used a mixture of oats and tares—2 bushels of each per acre—both because this produces a heavier forage crop, and one less liable to smother than grass seeds. I never had any difficulty in cutting down such crops with the ordinary reaping machines; and my rule was to cut as soon as the oats were fully shot. This was usually about the end of July, so that the seeds had a long time to get established before winter. My unvarying experience has been that by the following spring the seeds thus treated proved to be the earliest and best young grass that I had. Hay made from this mixture of oats and tares cut green is much relished by all kinds of stock, which thrive upon it. Let me say that if showery weather occurs when the hay-making is in hand, great care must be taken not to allow the cocks to stand long on the same site, else the seeds will be damaged; and, also, that when carried the stacks should be thatched as fast as they are built, as this kind of stuff is very liable to damage from rain. Let me add another caution—pigeons, both wild and tame, are so fond of tares that unless they are vigilantly harried early and late, from the moment of braiding until the second leaf is out, the crop will inevitably be ruined by these vermin. I claim, then, for this plan of sowing small seeds along with a forage crop of mixed oats and tares (1), that it entirely avoids the risk from annual weeds which is incurred when seeds are sown without any protecting crop; (2) it gives a valuable green crop to be converted into hay (or silage, if preferred), which, being mown before its seeds have even begun to form, has no appreciable effect in lowering the fertility of the soil; (3) it affords beneficial shelter to the young grasses and clovers at the stage of growth when they specially need it; and (4) from being relieved from this crop at the very beginning of autumn, the seeds have ample time to get well rooted and established before winter. Indeed, they will usually make such rapid and luxuriant growth at this stage, and present so tempting a pasture for lambs, that unless the owner exercises a strong control, both over himself and his shepherd, there is the utmost risk of irremediable damage being done by over-grazing at the very outset. The plan now described is no mere theory, but is the record of long-continued practice on a large scale, and under great diversity of soils and climate. I can recommend it to others with thorough confidence.

CLOTHING WALLS WITH IVY.

It is a common error that ivy is objectionable and even destructive to walls as a covering, fostering as it is said decay, and harbouring damp. Those who urge these objections must either have had few opportunities for observing its effects when well kept and properly managed, or they have observed very superficially indeed. It is no doubt true that if ivy is allowed to run wild and become a tangled mass of confusion, or if it is allowed to penetrate into cracks in the wall, or under eaves, or into the material of a roof, it will quickly work havoc; but that is no fault of the ivy, but of those whose duty it is to develop its usefulness and restrain its destructive tendency. Ivy properly kept may be made the very best protection for faulty walls against damp and the general effects of the weather. The point is easily demonstrated. Ivy that is properly trimmed and kept presents an equal and close mass of foliage to the weather, at such an angle as will prevent rain and snow from penetrating to the wall as effectively as if it were covered with slates for the purpose. If there is a flaw in a wall, such as a crack or bad brick or stone, in which any limb of the ivy may find room for development unobserved, then there is danger that it will work as the wedge when the thin edge is inserted; every course of the sap of the plant will be like the driving home of the wedge—slower, perhaps, but not less sure, certainly none the less effective because unobserved,—till the increased bulk of the limb disturbs the fabric and brings it to the ground. We have seen a case in which the roof of an ivy-clad turret was lifted visibly off the plumb by the increasing growth of the plant, which had been allowed to increase unnoticed, year after year, by those whose duty it was to keep it in proper order. But cases such as these only prove that it is a dangerous or destructive covering to a wall if it is neglected. It must be regularly trimmed, at least once a year, and no wall should be planted with ivy without first being put in a good state of repair. The best time for trimming ivy is March, before growth commences, and it should then be gone over with the hedge shears and clipped close. The eaves of the walls should be carefully examined at the time of trimming, and every particle of growth removed from the wall from four to five inches under these. The whole surface of wall and ivy stems should be brushed over afterwards with a hard broom, to dislodge dust and small vermin. For a hardy plant of comparatively free growth, ivy is by no means so easy to establish on walls as might be expected. It should be established in pots before being planted, in order to make the most successful start with it. It is a mistake also to suppose that it does not care for good soil. It is as fond of a bit of good rich soil as any plant, provided always it is well drained; good drainage it must have, but it derives no nutriment from the wall that supports it. Those seeming rootlets, they fulfil no function of the roots, but merely serve to support the plant in its position, and enable it to extend the area of its foliage. If in pots, the plants may be transplanted at any time or any season of the year. They are usually planted and the shoots nailed up to the wall at the same

time. This, though the common plan, is not by any means the best. It is long before the plants take to the wall with their aerial roots and fix themselves, and the older parts never do actually fix themselves, because the aerial roots are only emitted from the young shoots in the course of their growth. The best way to establish ivy is to lay the stems along the base of the wall after planting, and fix them close to it with pegs; then when growth commences the young shoots will take at once to the cool, moist bottom of the wall, and never look behind it afterwards. The practice of planting ivy as an undergrowth beneath trees, while very desirable for the purpose of clothing ground where little else would grow with verdure, involves some risk to the trees. If the ivy is allowed to climb on the trees it will certainly injure, and sooner or later kill them, if unchecked. It should therefore be prevented from attaching itself to the stems of the trees by careful annual attention. Nothing in the way of ornamental verdure will succeed better under the shade and drip of trees, but it must be watched, and kept thoroughly in check.—*North British Agriculturist.*

THE SUGAR QUESTION.

By the West Indian Mail just to hand, we have received copy of a paper on the above subject read before the Trinidad Agricultural Society by Mr. H. A. Fitt, and we subjoin the more important portions of it, though we must not be understood as thereby endorsing his views except as regards improved machinery and more economical management. We are persuaded that it is quite hopeless to look to the Home Government for help in the shape of countervailing duties on Bounty fed sugar, or for its sanction to the raising of a colonial loan, to pay off estate mortgages. Here, however, is the principal portion of Mr. Fitt's paper:—

"To meet the difficulties and dangers of our position many expedients have been suggested. Among them are the means of getting rid of the Foreign Bounty, the attempt to get extended to the colonies by the Government of the United States the most favored nation clause, and a reciprocity treaty as regards the West Indies with the United States Government. By means of a conference it was thought the bounties might be resented, but that course has been negatived, and the evil is allowed to remain in the futile hope that it will eventually cure itself. It behoves us to persevere in pressing the British Government to impose a countervailing duty, as the only ready and effective means of placing our sugar on a footing of equality with the foreign article. It is not thought by the United States Government that the most favored nation clause extends to the colonies; a different opinion appears to be held by Lord Derby, yet his Lordship has desisted from arguing on his own view of the case, and the matter has been dropped. May not this Association urge on Lord Derby to resume the discussion with the United States Government on the basis of that which he holds is contained in the treaty? The third proposition is yet in abeyance, and will remain so till we know what are the reciprocal advantages the States propose to give and receive.

"Whatever advantage may result to us from any of these propositions ought not to cause us to defer the attempt to reduce to the lowest point the cost of producing sugar. This may be effected partly by increased production from the same area of cultivation, by improved crushing power, and the many small economies it would be tedious to enumerate. Immigration which, by the number of coolies now in the island is through their consumption of excise and dutiable goods rendered self-supporting, requires in respect to the distribution of its cost to be by the Local Government reconsidered; a petition should be presented to the Legislature to that effect, and until that is considered, immigration should be suspended.

"By its suspension the heavy export duty of six shillings per hogshhead on sugar will be saved, and that much will at once be removed from the cost of production.

"Another and very important matter remains to be advanced, and for which I would bespeak an attentive consideration.

"Many sugar proprietors are paying a very high rate of interest on mortgages; great would be the relief if this rate of interest could be reduced, but this can only be effected by payment of the mortgage debt, the assistance to accomplish which may be afforded without risk or inconvenience by the Local Government. The proposition is not novel. Instances will be adduced to show that the Imperial Government, to relieve a suffering population, has advanced money at a rate of interest almost nominal, and the Local Government also on similar grounds has made considerable advances. About the year 1860 advances were made by the Local Government for the construction of railways in the Naparima and Chaguana, purely to assist the planters of those districts to get their produce to market, although at that time the Government was infinitely less rich in resources than it is now. These advances by a rent charge were repayable in twenty-four years, and were punctually defrayed. Another instance may be cited of equally statesmanlike views held more recently by the Government in respect to the construction of railways.

"Here then are two instances when the public purse has been readily opened; on the first occasion it may be said for individual benefit, on the second occasion to promote a great public object.

"A third demand now presents itself, when under the guarantee of the Government, the sugar planter, on the verge of ruin and more precariously situated than was the Naparima planter in 1860, may be enabled to effect a reduction of interest on his liabilities, and with other economic savings so far reduce the cost of his commodity as to meet and contend successfully with the unfair

competition with best sugar to which he is hopelessly exposed in the British market.

"An application to the Government of the nature shadowed forth, finds in full accord a precedent of British Legislation in 1880, under 'The Relief of Distress Ireland Act.' That Act provides for the issue of £750,000 at one per cent interest commencing in two years after the loan, and payable by thirty half-yearly instalments, solely for the relief of Irish distress.

"That which I am emboldened, under the precedents quoted, to suggest is a loan at four per cent interest and two per cent sinking fund, repayable by a rent charge to cover interest and sinking fund, at six per cent per annum, in twenty-seven years. The repayment would defray twenty per cent of the loan in nine years, forty per cent in fifteen years, sixty per cent in twenty years, and the whole in twenty-seven years. The money so advanced would be applied to the payment of mortgage debts, and the Government would thus acquire the first lien on the property. At the end of twenty-seven years the estate will have liquidated all of its mortgage liabilities, and that at no greater outlay than payment of the annual rent charge or six per cent—two per cent less than is now paid for interest alone.

"It is difficult to conjecture what would be the liability thus required of the Government, but it is not likely to be great, as large European houses possess the means and opportunity of borrowing to supply their wants as regards interest at the rate mentioned—it would only therefore be the less affluent of our planters that would be applicants for such relief, whose united claims may amount to £100,000. Should this scheme, simple in itself, presenting no difficult complications, and offering undoubted security, commend itself to this association, its adoption will at once render stable many tottering proprietors, prove to be a great lever in restoring value to property, and be the partial means of retaining in cultivation many sugar plantations that will be soon falling into decay, and which otherwise may eventually be abandoned.—*Planters' Gazette*, English paper.

AN ALARMING DISEASE AFFLICTING A NUMEROUS CLASS.

THE disease commences with a slight derangement of the stomach, but, if neglected, it in time involves the whole frame, embracing the kidneys, liver, pancreas, and in fact the entire glandular system; and the afflicted drags out a miserable existence until death gives relief from suffering. The disease is often mistaken for other complaints; but if the reader will ask himself the following questions he will be able to determine whether he himself is one of the afflicted:—Have I distress, pain, or difficulty in breathing after eating? Is there a dull, heavy feeling, attended by drowsiness? Have the eyes a yellow tinge? Does a thick sticky mucous gather about the gums and teeth in the mornings, accompanied by a disagreeable taste? Is the tongue coated? Are there pains in the sides and back? Is there a fullness about the right side as if the liver were enlarging? Is there costiveness? Is there vertigo or dizziness when rising suddenly from a horizontal position? Are the secretions from the kidneys scanty and highly coloured, with a deposit after standing? Does food ferment soon after eating, accompanied by flatulence or a belching of gas from the stomach? Is there frequent palpitation of the heart? These various symptoms may not be present at one time, but they torment the sufferer in turn as the dreadful disease progresses. If the case be one of long standing, there will be a dry, hacking cough, attended after a time by expectoration. In very advanced stages the skin assumes a dirty brownish appearance, and the hands and feet are covered by a cold sticky perspiration. As the liver and kidneys become more and more diseased, rheumatic pains appear, and the usual treatment proves entirely unavailing against this latter agonising disorder. The origin of this malady is indigestion or dyspepsia, and a small quantity of the proper medicine will remove the disease if taken in its incipency. It is most important that the disease should be promptly and properly treated in its first stages, when a little medicine will effect a cure, and even when it has obtained a strong hold, the correct remedy should be persevered in until every vestige of the disease is eradicated, until the appetite has returned, and the digestive organs are restored to a healthy condition. The surest and most effectual remedy for this distressing complaint is "Seigel's Curative Syrup," a vegetable preparation, sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White, Limited, 17, Farringdon-road, London, E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

Market-Place, Pocklington, York, Oct. 2, 1882.

Sir,—Being a sufferer for years with dyspepsia in all its worst forms, and after spending pounds in medicines, I was at last persuaded to try Mother Seigel's Curative Syrup, and am thankful to say have derived more benefit from it than any other medicine I ever took, and would advise any one suffering from the same complaint to give it a trial; the results they would soon find out for themselves. If you like to make any use of this testimonial you are quite at liberty to do so.—Yours respectfully,

(Signed) R. TURNER.

Seigel's Operating Pills are the best family physic that has ever been discovered. They cleanse the bowels from all irritating substances, and leave them in a healthy condition. They cure constiveness.

St. Mary-street, Peterborough, Nov. 29, 1881.

Sir,—It gives me great pleasure to inform you of the benefit I have received from Seigel's Syrup. I have been troubled for years with dyspepsia; but after a few doses of the Syrup, I found relief, and after taking two bottles of it I feel quite cured.

I am, Sir, yours truly,

Mr. A. J. WHITE.

WILLIAM BRENT.

"Hensingham, Whitehaven, Oct. 16, 1882.

"Mr. A. J. WHITE.—Dear Sir,—I was for some time afflicted with piles, and was advised to give Mother Seigel's Syrup a trial, which I did. I am now happy to state that it has restored me to complete health.—I remain, yours respectfully,

(Signed) JOHN H. HIGHTFOOT.

August 15th, 1883.

Dear Sir,—I write to tell you that Mr. Henry Hillier, of Yatesbury, Wilts, informs me that he suffered from a severe form of indigestion for upwards of four years, and took no end of doctor's medicine without the slightest benefit, and declares Mother Seigel's Syrup which he got from me has saved his life.—Yours truly,

(Signed) N. WASS,

Chemist, Calne.

September 8th, 1883.

Dear Sir,—I find the sale of Seigel's Syrup steadily increasing. All who have tried it speak very highly of its medicinal virtues; one customer describes it as a "Godsend to dyspeptic people." I always recommend it with confidence.—Faithfully yours,

(Signed)

VINCENT A. WILLS,

Chemist-Dentist,

Merthyr Tydvil.

Preston, Sept. 21st, 1883.

My Dear Sir,—Your Syrup and Pills are still very popular with my customers, many saying they are the best family medicines possible.

The other day a customer came for two bottles of Syrup and said "Mother Seigel" had saved the life of his wife, and he added, "one of these bottles I am sending fifteen miles away to a friend who is very ill. I have much faith in it."

The sale keeps up wonderfully; in fact, one would fancy almost that the people were beginning to breakfast, dine, and sup on Mother Seigel's Syrup, the demand is so constant and the satisfaction so great—I am, dear Sir, yours faithfully,

(Signed)

W. BOWKER.

CALCUTTA :—SATURDAY, FEBRUARY 28, 1885.

[No. 9.]

Crop and Weather Report.

[FOR THE WEEK ENDING THE 18TH FEBRUARY, 1885.]

General Remarks.—Rain has fallen in several districts in Bengal and in the Central Provinces, in two or three places in the Punjab, at Gowhati and Dibrugarh in Assam, and (Lanjam in the Madras Presidency. The fall has been of benefit to the crops in Bengal, but in some places in the Central Provinces it has caused slight damage.

In Madras and Mysore prospects remain unchanged. In Coorg threshing of rice is almost complete. The rabi harvest continues in places in Bombay and prospects are good. In Hyderabad, Central India, and Rajpootana, agricultural prospects continue satisfactory. The prospects of the rabi are excellent in the Punjab. In the North-Western Provinces and Oudh prospects are still favourable, though in some districts the crops have suffered from blight and insects. In Patabgurh the opium crop has been considerably damaged by hail. Cloudy weather prevails in the Central Provinces, and is not favourable to the crops. In the southern districts, wheat is fast ripening, and linseed harvesting is in progress.

In Bengal the rabi harvest continues, and lands are being prepared for the coming crops. In the Gya District 637 persons are employed on road works and there are 38 persons on the relief register. In Assam standing crops are doing well; mustard and sugarcane are being cut, and ploughing for the ensuing crop has commenced. In British Burmah the rice harvest is over, and crops are being housed.

Cholera is increasing in Travancore, but abating in Coimbatore and Tanjore. Smallpox exists in several provinces, otherwise the public health is generally good; prices are generally stationary.

Madras.—General prospects fair except in parts of Bellary and Anantapore.

Bombay.—Rabi harvest continues in parts of five districts; standing crops slightly injured in a few places, but generally in good condition; gram, wheat and cotton withered in parts of Kaladgi; scarcity of fodder and drinking water continues in several talukas of Dhavai and Belgauin and of fodder in parts of Kaladgi; cholera and cattle disease in parts of six districts; smallpox in parts of ten, and fever in parts of fifteen districts.

Bengal.—There has again been some rain in a considerable number of districts throughout the province; it has benefitted the standing crops generally; harvesting of rabi crops is going on, and sowing operations of boro paddy are nearly completed in Dacca; lands are being prepared for the ensuing crops; prices of food-grains almost stationary; cholera and smallpox prevail in many districts.

N.-W. Provinces and Oudh.—Weather cold; some crops have suffered in places from blight and insects, and opium in Patabgurh from hail; general prospects are however still favourable; prices continue steady, and the general health is good.

Punjab.—Slight rain in Rawalpindi and Shahpore districts; some cases of mouth-and-foot disease among cattle in Khussat tahsil, Shahpore district; health and prospects in rest of provinces good; prices slightly rising in Lahore and falling in Rawalpindi districts; stationary in other districts.

Central Provinces.—The late rain has caused slight damage in places; but as it fell after flowering had been completed and seed had set, the injury which has resulted is inconsiderable; fungoid disease has appeared in the northern district, but not, it is believed, to any great extent; in the southern districts the wheat is fast ripening and linseed harvesting is in progress.

British Burmah.—Cholera prevalent in one township of Akyab district, in towns of Promé and Shwedoung, and Henzada and Thongwa districts; slight in Rangoon town, parts of Tharruaddy and Amherst districts; smallpox prevalent in Henzada, otherwise public health good; slight cattle-disease in Bassein and Thongwa Districts; crops being housed.

Assam.—Weather seasonable; mornings and nights cool; land being ploughed for rice, but rain wanted to facilitate ploughing operations; sugarcane being cut; prospect good; public health fair.

Mysore and Coorg.—In Kola and Tumkur crops suffering from want of rain; water and fodder becoming scarce; general health good; prices rising.

Benar & Hyderabad.—Weather clear; cotton-picking nearly completed; rice crops flourishing; wheat 22 and jowari 26 seers per rupee. Rabi crops in ear and thriving; prospects good. Standing crops prospering; rabi sowings in progress; general health good; prices stationary.

Central India States.—Weather changeable but sky clear; health good, prices falling.

Rajpootana.—Harvest prospects good; some fever reported in Todgurh and in Ajmere city, but health of district is generally good.

Letters to the Editor.

THE AGRICULTURAL RESOURCES OF INDIA.

TO THE EDITOR OF THE TIMES.

SIR,—In the *Times* of last Saturday you publish a report of Mr. Buck's paper on "The Agricultural Resources of India." It is disappointing to find that in the paper in question the situation and difficulties of the Indian peasant have not even been touched upon, and that where the need for irrigation has been alluded to, no mention has been made of the advisability of holding out inducements to the people to embark their labour and capital in such work as is within their capabilities. With your permission, I propose to offer a few remarks upon both of these points.

The principal point in the agricultural situation of India may be briefly described by saying that, with the exception of land fertilized by rich river water, and of certain very limited tracts where the population is thin, and the feed for cattle ample, the people are living not on the interest, but on the capital of the soil. Nor does it need many words to explain this. Examine the scanty manure heaps, and you will find that they consist almost entirely of the dung of lean cattle, and of its ashes. The value of this manure may be estimated by stating that the dung of grass-fed cattle in England contains little more than 1 per cent of manurial matter. Whence, then, are to be supplied the phosphoric acid, lime, potash, and nitrogenous matters which are consumed and exported, and whence that vegetable matter which is now entirely consumed by cattle, but which is so necessary for the maintenance of the physical condition of the soil? It is evident that, under existing circumstances, but a very infinitesimal quantity of these manurial agents can be supplied to the soil.

Speaking generally, then, it is certain that, with trifling exceptions, the soils of India must not only be extremely exhausted, but also in the worst physical condition, and therein lies the grand evil and difficulty of the agricultural situation. That having been clearly grasped, the duty of the Government is plain. It must endeavour to provide the people with the means of economizing to the utmost the existing manurial resources, and, secondly, search for fresh manurial agents and show how they can be utilised. As the first point, it is absolutely necessary to provide timber reserves on the lands of every village, where space can be found for the purpose, and these would supply wood for fuel and leaves for litter, for the want of which the urine of the cattle—the most valuable portion of the excreta—is now entirely lost. As to the second point, the Government must search for potash, salts, and mineral phosphates, and having found them, explain their use to the people. It may be thought that whatever exists in India as regards such resources is already known. There is reason to doubt this. I have been repeatedly assured by Government authorities that there was no hope of finding the mineral phosphate of lime in Mysore, and yet last winter I found that a railway engineer had recently discovered large deposits of apophyllite—a discovery of the greatest value to the planters in the province, and which will, of course, be equally so to the native farmers when they are taught to appreciate the value of mineral phosphates. Much, then, may be done by the State to aid the farmers in contending with their

greater difficulties—difficulties which, as yet, the Government has never recognized.

Your space is so valuable that, as regards the second point of importance in the agricultural situation—the holding out of adequate inducements to the Indians to invest labour and capital in petty irrigation works—I cannot in this letter venture to offer any remarks.

I remain, obediently yours,

ROBERT H. ELLIOT.

Clifton-park, Kelso, N. B., Jan. 26.

Editorial Notes.

THE report on the prospects of the wheat crop in the Punjab, for the month of January, is as follows:—"Wheat prospects same as before reported on 15th January. Season most favourable."

FRANCE appears to be no better off than her English neighbours in the matter of trade and manufacturing vitality. A summary return of imports and exports for the past year, as compared with that of 1883, shows a very large falling-off in three of the four general descriptions of national products, and establishes the universality of the industrial depression of 1884. The reduction on the imported articles was general. Under imports the abatement is striking, amounting to no less than 281,000,000*l.* A large part of this diminution, however, is due to the reduced requirements of foreign food products, which are not necessarily connected with trade depression. But the imports, both of raw materials and of manufactures, have also largely fallen off, the latter by 60,700,000*l.*, and this diminution (observes the Paris correspondent of the *Times*), and the considerable reduction in the demand for raw materials, are decidedly signs of importance. As regards the falling-off in the demand for raw materials, the same correspondent says, it marks a state of trade which must cause really patriotic French statesmen serious alarm. Under exports, the chief source of diminution is the iron manufactures. The French exported during the past year 91,400,000*l.* less manufactures than in 1883. The difference, as between 1884 and 1882, was 43,000,000*l.*, so that the depression in this respect has more than doubled.

Messrs. JAMES AND HENRY THOMSON, in their fortnightly circular, say:—"Since the 15th inst. 12,900 packages have been catalogued for sale, including 1,940 from Ceylon and 700 of reprinted and second hand Tea. With a more general feeling of confidence the market has experienced a sensible improvement, the dealers being encouraged by a better demand from the country and by the improved character of the Teas now coming forward. Competition has been exceptionally brisk for fine qualities, and in our sales have been made of Pekoe and Broken Pekoe between 1*s.* 6*d.* and 2*s.* 6*d.*, showing decidedly higher prices than have been obtainable for some time past, notwithstanding the augmented supply of good Tea resulting from improvement in the tea manufacture from Assam and Dooars, and the arrival of some superior "autumn flavoured" teas from Dooars and elsewhere. There is also a movement in the value of good liquoring teas of all makes between 1*s.* and 1*s.* 6*d.*, especially Pekoes, but inferior qualities remain at former prices. In teas under 1*s.* there is not any quotable change beyond a hardening tendency for the best Broken and Souchongs, coarses and dull liquoring kinds of both leaf and broken remaining neglected at previous rates. The more varied selection of quality now offering as compared with the supply at the end of last year, is undoubtedly an attraction to the buyer, and should facilitate the sale of the balance of the crop, making the result of the year's working more satisfactory to producers and shippers than at one time seemed probable. About 41 million lbs. have now been sold, leaving 24 millions to be disposed of—assuming that the receipts from all ports reach our estimate of 65 million lbs. Last year between 23 and 24 million lbs. were sold between 1st February and 30th June."

THE third report on the prospects of the cotton crop in the Bombay Presidency, for the month of January, is as follows:—"Sind, in Kurrachee, excessive rain worked harm, elsewhere

crops are good, no figures. Glzerat, area about average, but condition below. Sown late in Broach, better in Kathiawar, especially in two divisions; for the rest the crops are fair. No report from Baroda. Deccan figures incomplete. In Khandesh the season late, and though harm caused by a break, followed by excessive rain and cloudy weather, the crop promises to be fair, elsewhere the area very much less than usual, in fact, it is quite insignificant; causes, total failure of early rain and anticipated repetition of damage by late heavy rains which in fact did again work much loss. In Sholapore, crop almost a complete failure; scarcely better in Nagar and Poona, slightly better in Nasik and Satara. Southern Mahratta country, condition very variable, average area and crop in three talukas of Dharwar, and fair crop elsewhere, but complete failure almost throughout Kaladgi, and in parts of Kolhapore; area lessened by absence of rain in black soil district. Belgaum, two talukas estimate two or three annas, elsewhere six to eight annas. Kolhapore, except in one taluka, may show a six-anna yield. Shedding, during cloudy weather, has been prevalent in the best crops."

AN exhibition of ploughs and ploughing was held at Kethu, in the Nilgiris Division, Madras on the 2nd instant, at which a large number of Badagas, from Merkunad, Paranginad, and Todanad, were present to witness the working of the several ploughs exhibited. The first trial was made on gently undulating ground, which had been for many years brought under the plough, but for the last two had been fallow. The soil was a very light loam, very easy to plough, and was in good condition for ploughing. The top layer of about 2½ inches (the depth usually reached by the ordinary Badaga plough) was apparently much easier to stir than the soil lower down, which was much harder in consequence of not having been moved by former ploughings. Each plough was put on a separate plot of 1200 square yards. The bullocks were the ordinary ploughing bullocks of the district, with Badaga drivers and ploughmen. The conditions were thus as nearly as possible equal for each plough. In judging the results, the following points were taken into consideration: (1) quality of the work—(a) depth of furrow, (b) turn-over, (c) general appearance; (2) quantity, i.e., the number of square yards ploughed in the given time, an hour and a half. According to the method of marking adopted by the judges, the work done by the respective ploughs was valued as follows:—

Full Marks - 165.

1. Massey's Indian ryot plough	...	92
2. Subject Ransome and Son's wheel plough	...	64
3. Massey's C. P. plough	...	61½
4. Badaga plough	...	50
5. Avery's "Hindoona" plough	...	45
6. Avery's "American" plough	...	36
7. Oakes and Co's small Swedish plough	...	39

In the second trial four selected ploughs were put on separate plots of 600 square yards, on a steepish hill side; soil much the same as in the first trial; Badagas' bullocks and ploughmen, assisted by the ploughmen sent from Madras.

AS regards the quality of the work done in this trial, the judges considered that Massey's C. P. plough, Massey's Indian ryot's plough, and Avery's American plough were equal to one another, and decidedly superior to the Badaga plough in the two important points of turn-over and depth of furrow, whilst in the matter of quantity, i.e., the number of square yards ploughed in the given time, one hour, the following are the results:—

	Sq. Yds.
Massey's C. P. plough	509
Do. Indian ryot plough	450
Avery's American plough	349
Badaga plough	270

The general opinion of those who witnessed the ploughing seemed to be that Massey's C. P. plough was the best implement for this district, although the result obtained in the first trial placed it in the third place, and far below the other ploughs, Massey and Co's. It was, however, evident that owing to the unsteadiness of the cattle and the want of skill in the ploughmen, the respective merits of the several implements could not be said to have been fairly ascertained. Avery's ploughs and the small Swedish plough exhibited by Messrs. Oakes and Co. are excellent ploughs, and their failure was principally due to want of proper skill in handling, and to the use of untrained cattle. After the ploughing was over, a Badaga purchased the

C. P. plough and took it away with him. Considering all the real merits that the Badaga plough possesses—its simplicity, its portability, and its cheapness—it is suggested that good may be effected by stimulating the Badagas to improve it, and, with this view, to offer prizes to native manufacturers for improved ploughs. And looking at the Badaga cattle, whose chief defect is not so much want of strength as want of training, it might be well to endeavour to effect a remedy by offering rewards for steady and well-trained animals. Had such animals been available for these trials, the superiority of the European and American ploughs would have been much more clearly demonstrated. Other ploughs were sent, such as the large Swedish ploughs, &c., but as these ploughs require a class of cattle not produced on these hills, they are not mentioned in this report. It was remarked that the wheel plough, by Ransome and Sims, appeared to do its work very easily, although drawn by perhaps the worst pair of bullocks in the show. It is a well-made implement, and probably the best of those exhibited, but it is too expensive for the Badagas, who pull a long face even at the prices put on Avery's and Massey's ploughs.

* *

From a correspondence which has just been published, under the authority of the Government of Madras in the Revenue Department, it appears that, with the exception of that Presidency, no duty is levied on poppy heads in any other part of India, and that no passports or permits are issued by the Indore Agency, authorizing exports from Malwa. It is a fact that poppy heads are exclusively used for medicinal purposes, and the trade in them is very small. Consequently great hardship is suffered by medical men and their patients from the difficulty and, at times, the impossibility of procuring this article of medicine, owing to its being taxed and brought under the opium rules. Under these circumstances, the Deputy Collector, under the Collector of Madras, suggested that poppy heads be excluded from the articles subject to the opium rules of 1880. The Collector of Madras did not, however, think that in the face of the opinion expressed by the Chemical Examiner, that poppy-heads contain narcotic properties, the Board would alter their view previously expressed in their proceedings, and would probably hold that the simple license fee of Rs. 3 will not preclude the public from obtaining them readily. But his view was that they should be exempted from the opium rules. The matter was subsequently referred to the Board of Revenue, who held that the poppy heads cannot be excluded from the operation of the Opium Act, as sec. 3 defines opium so as to include poppy heads. But taking into consideration the fact that they are exclusively used for medicinal purposes, and the trade in them is very small, the Board recommended to Government that the fee of Rs. 3 levied on licenses to sell poppy-heads be reduced to 8 annas. The Government of Madras has approved of the recommendation.

* *

The report on the prospects of the wheat crop in the Bombay Presidency for the month of January is as follows:—“Sind, figures not yet available. Crop progressing well, and, in places, show promise of a good season. Guzerat, increase in area 45 per cent over last year, due to replacement of damaged cotton by wheat; benefit to wheat from rain-fall in December; generally crop excellent. No information from Baroda and Kathiawar. Reports from P. Jangur and Cutch coincide with those from Regulation Districts. Deccan, Khandesh figures now received, 255,849 acres, or a decrease of 126,619, compared with last year, when, however, the area was abnormally large. In the Deccan, the average is up to average, and everywhere the crop was benefited by the December rain, but latest reports show a general prevalence of frost, except in Khandesh, where it is trifling, the crop will be considerably below the average. Southern Mahratta country, increase in area considerable but really a nominal one; wheat was put down because it was the only crop in season at the time of the rain; where increase greatest, promise of crop is poorest, for the wheat was sown too late and in uncongenial soil. Dew almost quite absent, due perhaps both to high range of temperature and dryness of atmosphere. In Kaladgi crop is nearly everywhere a total failure.”

With the sanction of the Governor-General in Council, the Chief Commissioner of the Central Provinces has issued the following Rules under Section 1 of the Agriculturists' Loans Act (XII. of 1884):—

Badaga allotment, to which loans made to agriculturists may be debited, will be made to each division for each financial year. Commissioners will distribute this allotment as their discretion among the districts of their division, and will have the power of transferring the amounts so distributed from one district to another. But expenditure in each division must be kept within the amount allotted to that division. If an additional allotment is required, application may be made to the Chief Commissioner by telegram if necessary. The maximum amount which a Deputy Commissioner may advance in respect of a single tenure or holding, on his own responsibility, shall be Rs. 300. For loans exceeding this sum he shall obtain the sanction of the Commissioner. The Commissioner may sanction a loan up to any amount, provided that the allotment for his division be not exceeded. Loans may be made to—

- (a) owner or occupier of established holding having a transferable interest in the same, or able to furnish one or more sureties having a transferable interest in land;
- (b) occupiers of an established holding, and not being able to furnish in security, a transferable interest in land.

“Without the special sanction of the Commissioner no loan made under Rule III (a) shall exceed—

- (1) if the security be the tenure of a mortgagee or plot-holder, eight times the annual revenue assessed or assessable on it;
- (2) if the security be the holding of an absolute occupancy tenant, five times the annual rental.

“Without the special sanction of the Commissioner, no loan made under rule III (b) shall exceed—

- (1) in the case of an occupancy tenant, three times the annual rental of the holding;
- (2) in the case of an ordinary tenant, twice the annual rental.

“Provided that, if the loan be made on the joint and several security of two or more tenants, its amount shall not, without the special sanction of the Commissioner, exceed—

- (1) in the case of occupancy tenants, twice the sum of their annual rentals;
- (2) in the case of ordinary tenants, one and-a-half times the sum of their annual rentals.

“Interest upon loans shall be at the rate of one anna in the rupee, or 6½ per cent per annum. But the Chief Commissioner may, on special cause being shown, sanction the granting of loans at a lower rate of interest, or even without interest. The period fixed for the repayment of loans shall not be longer than 10 years. Ordinarily loans made for the purchase of seed should be repaid from the crops produced from the seed; and loans made for the purchase of plough cattle should ordinarily be repaid within three years at most. The dates fixed for payment of instalments should usually be those fixed for payment of land revenue. When loans are not repaid on the dates fixed, interest at 12½ per cent is chargeable, at the discretion of the Deputy Commissioner, upon all overdue instalments of principal and interest, or of principal where a loan is made without interest. When any portion of a loan made under these Rules is found to be irrecoverable, a special report must be submitted to the Chief Commissioner, through the Commissioner. A register of loans made under these Rules shall be maintained in each taluk in Form I. (appended), a separate page being allotted for each loan. Annual statements of loans and collections shall be submitted to the Chief Commissioner, in Forms marked I and II, by Commissioners on the 1st of June, for the year ending on the preceding 31st March. Deputy Commissioners shall submit the statements to Commissioners on 1st May.”

* *

The report on the prospects of the wheat crop in the North-Western Provinces and Oudh, for the month of January, is as follows:—“The wheat area in the United Provinces is returned for January at 5,208,652 acres, which is less than the December estimate by 323,518 acres. The explanation of this large difference, is that the January area has been obtained by patwaris' field inspections, whereas the December area was an estimate based on the increased width of the rain sowings generally, and in the principal wheat districts of Meerut and Rohilkhand, extensive areas, which were supposed to be under

pure wheat, have been on inspection found to be under mixed crop, and therefore excluded from the forecast. Taking 100 to denote normal, the area now under wheat in the United Provinces stands at 104. The rain-fall of January was not sufficient in the Agra, Allahabad, Jhansi, Benares, and Lucknow Divisions, but over the rest of the provinces it has materially improved the prospects of the crop. Damp cloudy weather has caused slight rust, and hail has here and there done some damage. Adopting 100 to denote full average, the condition of the crop is as follows:—1,581,687 acres at 100, 649,353 acres at 90, 2,111,557 acres at 84, and 863,055 acres at 75.

* *

On the 30th of December last the Government of Madras had sent a telegram to the Government of India on the subject of the scarcity at Bellary, and commencement of the earth-work of the Guntakul-Hindupore railway. The reply received was that no funds will be available for some time to come; but if the commencement of earthwork for relief purposes be indispensable, the Madras Government are at liberty to proceed with it provincially, under paragraph 8 of the Resolution, in the Financial Department, No. 3353, of 30th September 1881, and will be recouped under the rules established for such cases whenever the line can be regularly started for construction as an Imperial work. On the 22nd January, Mr. Cotton, Acting Collector of Bellary, writes to say that the migration from villages in the Bellary and Alur taluks is increasing, and that the people are leaving in large numbers in search of employment. They are reported to have gone to the Adoni and Hospet taluks of this district, to Kurnool, the Nizam's territory and Mysore. In a report received from the Tahsildar of Bellary, it is stated that 4,775 men, 3,193 women, and 2,178 children have already deserted, and that the people are preparing to go in still larger numbers. Similar information is transmitted weekly by the police, and there is no question that a general movement in search of work has set in throughout the taluks of Bellary and Alur, which have been most seriously affected by the drought. Elsewhere the situation is not so grave. The collector had just completed a tour round the district, and could testify to the fact that the kungari crops are a complete failure throughout the black soil tract, and will be scanty on the red and mixed soils. The harvest of mungari crop is done, and he fears that the wanderers will not be able to find work in connection with agricultural operations anywhere, and will eventually return to their homes disappointed and enfeebled by privation. Under these circumstances he earnestly pressed upon Government the necessity for starting the Guntakul-Hindupore railway works without further delay. The Madras Government lost no time in wiring to the Supreme Government the critical state of the district, and in reply was empowered to spend whatever sum was urgently needed on relief works Hindupore railway, out of the balance of 20 lakhs which the Government of India, in the Finance Department, directed them to keep. Arrangements have therefore been made for placing funds at the disposal of the Public Works Department, from the Provincial balance.

* *

HERR W. BURCK, Assistant Director of the Buitenzorg Botanic Gardens, Java, has written, as an appendix to the report on these gardens for 1882, a most elaborate memoir, embracing all that is at present known of the apparently large number and great variety of the trees which produce the gum called gutta-percha. The gum varies in quality as the trees do in species (some of them appear to be figs), and the soil and conditions suitable for the growth of gutta-yielding trees vary, as in the case of India-rubber trees, from clay, loam, and sand to swamp. The *Tropical Agriculturist* believes that there are some of the gutta-percha-yielding trees in the forests of Ceylon, and others of the species proved to be most valuable can be introduced there; but it is in the vast forests of Borneo, Java, and the islands of the great Eastern Archipelago generally, that scope is afforded for identifying the trees and preserving them from extermination. The difficulty of identifying the gutta trees is increased by the small size of the blossoms, by the fact that blossoms and fruits do not co-exist on the trees, and the trees themselves are, when full grown, very

tall. The natives who make their living by collecting the gum can give but vague information, their accounts of the number of trees they fell to secure a picul of gum (133½ lbs.) varying from 100 trees to 250. Herr Burck believes that the major portion of the trees which produce gutta-percha are as yet unknown to science. There is, therefore, wide scope for research by him or some other naturalist. The most varying products go into the market by the same name, and are often mixed together, only to be separated by an expensive process before being used to coat cables. Herr Burck promises further information at the conclusion of his investigations in Padang country.

* *

In the memorandum published by the Government of India on the 20th January from the information then available, it was stated that, in respect of over eighteen million acres, or 9-13ths of the gross wheat area of India (including Native States), the condition and prospects of the wheat crop were on the whole up to the average, and that a bumper crop might be anticipated in the most important province of all—the Punjab. It was also anticipated that the wheat crop in Rajpootana and the Central India States was quite up to the average both in area and condition. The anticipations thus formed are borne out generally by the later information which has now been received. In the Punjab, prospects which were excellent in January continue unchanged, and the season is reported to be most favourable. In the North-Western Provinces and Oudh, more accurate measurements have shown the area under wheat to be about 5½ instead of 5¼ millions of acres, as previously supposed. The benefit expected from the January rains has been realised throughout a great portion of the province. About 30½ per cent of the area under wheat is expected to yield a full average crop, about 12½ per cent, a nine-tenths crop, about 49½ per cent, a four-fifths crop, and about 16½ per cent, a three-quarter crop. In the Central Provinces, where the acreage under wheat is believed, though on somewhat uncertain data, to be below the average, prospects are generally excellent, and a full crop is expected on the greater part of the area sown. In one district only is less than a five-eighths crop anticipated. In the Bombay Presidency, prospects are good in Sind and excellent in Guzerat, where the area under wheat is greater by nearly one-half than usual, and where much benefit has resulted from the December rain. In the Deccan, where the area sown is normal, the crop has, except in the Khandesh district, suffered from rust. In the Southern Mahratta country, the prospects are unsatisfactory, and in Kaladgi, the crop is reported to have failed generally. The report received from the Berars shows the area under wheat, though larger than usual, to be less by about 25,000 acres than was anticipated. The prospects of the crop are satisfactory. A special report received from Cashmere states the area under wheat to be nearly half-a-million of acres, on which a full crop is anticipated.

* *

At the recent half-yearly meeting of the Colonial Bank the Chairman, Mr. H. H. Dobree, said that there had been a number of most desponding—and, as he thought, over-desponding—letters from the proprietors in the West Indies and other sugar-producing colonies, stating that the cultivation of cane sugar could never be carried on again at a profit; and those letters had naturally frightened persons as to the future of the Bank. As regarded its future, however, he would say that the West Indies had passed through, and had recovered from, quite as severe a crisis as they were now passing through, and they had been fairly prosperous, at least, for the last 15 years. The present great fall in the price of sugar was in the main caused by the unduly fostered production of beet—fostered unduly by bounties—and to such an extent had that production been encouraged, that the sugar had been forced down owing to the enormous amount which had been produced beyond what the consumer could take, to as low as £10 per ton. That price was stated, by those who were fully competent to judge of the question, to be £5 a ton below the price for which sugar could be produced in any part of the world, and under the most favourable circumstances. That was a state of things which could not last long. It

was impossible that such an article as sugar could long be produced below its cost. The best interest was suffering quite as much as, if not more than, the cane sugar interest. In the cane sugar interest, especially in the West Indies, there was every prospect of a reciprocity treaty being concluded with the United States, which would enable the States to absorb the whole of the crops of the West Indies, and, he had no doubt would be of immense advantage to the West Indies generally. It was believed by gentlemen who had some experience of the management of sugar estates, that although possibly in some of the smaller West India islands cane might go out of cultivation, yet sugar could be produced as cheap, or even cheaper, in Demerara, Trinidad, and Barbadoes as in any part of the world. Another matter of some importance to them was that the West Indies were not so entirely dependent upon the produce of the sugar cane as they were some ten years ago. Of course, it was their great staple product, but there was a very large production of cocoa, coffee, spices, and fruit—the trade now springing up in fruit with the United States was very large indeed—and this all tended to make the West Indies to some extent independent of sugar.

THE following report has been received regarding the prospects of the wheat crop in Cashmere :—"The total area under wheat in Jummoo territory averages 560,212 *kamaons*, equal, at eight-ninths of an acre, to 497,966 acres. A full crop is said to reach the total of 20,75,664 maunds, being rather more than 4 maunds an acre. The present is the most promising crop seen for many years, and is therefore expected to exceed the above estimate of a full crop."

IN December last, says a Madras contemporary, Mr. M. A. Lawson, the Director of the Government Cinchona Department, Madras, represented to Government that he had discovered certain thefts and defalcations in the Nediwuttum Cinchona estates. The Government thereupon directed Mr. Burrows, the District Magistrate, and Mr. R. D. Shortt, the District Police Officer, to proceed to Nediwuttum in order to make a thorough investigation into the whole matter. This investigation lasted for many days, and the books of the whole department were thoroughly examined, the result being that Mr. Hillier, the Superintendent, was charged with criminal breach of trust in respect of certain sums as a public servant, and was committed for trial at the Sessions Court of Coimbatore. During the examinations of the books, it came out that the Manager of the head Cinchona Office at Ooty had also misappropriated certain sums of Government money, and had received bribes from a certain contractor, *viz.*, Isool Sait. He also was committed for criminal breach of trust as a public servant, and for bribing a Government servant. The case occupied the Sessions Court at Coimbatore nine days. Mr. Hillier was defended by Mr. Cowdell and the whole bar of Ooty. The prosecution was conducted by Mr. Philip Smith, instructed by Mr. Shortt. After a protracted trial the Sessions Judge delivered judgment on the 14th instant. Mr. Hillier was convicted of all charges against him, and sentenced on the first charge to nine months' rigorous imprisonment and a fine of Rs. 60, with an alternative of two months' rigorous imprisonment; on the second count of the first charge to nine months' rigorous imprisonment and fine of Rs. 50, commutable to two months' further imprisonment; on the third count of first charge, he was committed to prison for four months and fined Rs. 30, commutable to two months' further imprisonment. On the first count of the second charge, four months' imprisonment and fine of Rs. 30, commutable to two months; and second count of second charge, two months' imprisonment and a fine of Rs. 5, commutable to one month's additional imprisonment. The Manager, Venkatarathnam Naidoo, was sentenced to two years' rigorous imprisonment and a fine of Rs. 200, or an alternative of one year's additional imprisonment.

THE *Gardener's Chronicle* writes :—"Our readers are familiar at least with the reputation of Coca, or *Erythroxylon* Coca, the leaves of which are used as a stimulant, like tea or coffee, and which allay hunger, and avert the pangs of fatigue. This much has been known for years,

and was put to the test by the late Sir R. Christison. Its properties were supposed to be due to a substance identical, or nearly so with *thein*, the active principle of tea and coffee. Latterly, this principle has been isolated, and has been found to possess such anæsthetic properties as even to render the eye insensible to touch. Its use in surgical operations is, therefore, likely to become very important, and to be extended to tooth-drawing and other minor surgical operations. At present, its high price forbids more than experimental use, but the results have been so uniformly successful, that there is little doubt that, as the demand increases, the manufacture will be extended and cheapened." The Secretary of the Madras Horticultural Society states that "*Erythroxylon coca*, with its near and indigenous relative, *Erythroxylon monoginum* (*Sethia indica*) grows freely in the Society's gardens."

THE report for January on the prospects of the wheat crop in the Central Provinces, is as follows :—"The northern district received frequent showers of rain during January, and these prospects have improved; Hoahungabad alone estimates an out-turn of less than ten annas. Damp weather has led to some, but not much, fungoid disease in the southern districts. Prospects continue excellent, and a full crop may be expected on a large portion of the area sown. It has been impossible as yet to obtain returns of area which are in any way reliable."

WE learn from a home paper that, through advancing years and failing health, Professor John Wilson, who has for many years sustained the dignity of the chair of Agriculture in the Edinburgh University contemplates resignation at the close of the present session, two months hence. The Professor's shoes will not be easily filled. His ideas on the practice of agriculture did not chime in with those of Scotch agriculturists in every particular. That was hardly to be expected, seeing that his knowledge of practical agriculture was largely acquired in the southern counties of England. By his students, Prof. Wilson was, and is, much esteemed, and in the celebrated educational establishment in which he has so long had the honour of a chair, he was highly respected, as is evidenced by the fact that he has for a considerable number of years acted as secretary to the Senatus. Speculation is already rife in certain quarters as to who his successor should be. Of the several probable candidates who have yet been named, the two that have been received with most favour are Dr. Aitken, chemist to the Highland and Agricultural Society, and Professor Wallace, of Cirencester.

THE report for January on the prospects of the wheat crop in the Berars, is as follows :—"Area under wheat 819,054 acres, two per cent above the average, which is 803,055 acres, for the Province. The crop is progressing favourably. The late rains have not been so injurious as was feared. An out-turn of twelve annas is expected from the present state of the crop."

MR. JOHN HUGHES, the eminent chemist, writes to the *Tropical Agriculturist*, published at Colombo : "I am glad to hear tea is progressing so favorably, but I agree in thinking it most unwise to pull up good coffee trees to make a tea garden. If a change is desired, why not do so gradually, planting tea between the coffee; and thus protect the land from exposure to tropical heat and wash? After my analyses of the Indian cinchona soils, which were so rich in nitrogen, I feared your Ceylon soils would not do generally for cinchona, being too poor in organic nitrogenous matter, but for tea I have every hope, and my friends in Mining-lane now speak most favorably, very different from what I heard in 1878 on my return from Ceylon, when planters had but little experience in preparing tea."

A HOME contemporary says that of the companies already formed to work the gold fields of the Transvaal, it cannot be said that any one of them has as yet proved successful, though the prospects of each seem to be brighter just now than at any other period of their history. The difficulties between the Lisbon-Bank Company and Mr. Gwynne-Owen having been settled out of court, the manager and directors will now be in a position to devote their sole attention to the development of the

mine. It is also said that the directors of the Spitzkob Company have decided to pay the amount of the award into court, and at once get possession of Silo Hill, so that the legal proceedings will go on contemporaneously with the working of that part of the property by the company's manager. With regard to the Transvaal Gold Exploration and Land Company, the directors have issued a circular stating that advices just received from Mr. Williams, by cable, state that the quartz crushed during the month of December amounted to 413 tons, and yielded 130 ozs. of gold, which is now in transit. As last reported, the quartz at Ophir Hill has deteriorated, and although Mr. Williams noted a slight temporary improvement, he now telegraphs to the committee that he has been compelled to stop the works there owing to the veins producing too small a quantity of payable quartz. The committee regret to state that the results so far obtained from the crushings of the stacked quartz purchased from the diggers have not satisfied their expectations, nor the representations made on this head on the purchase of the property. From the assays of samples, said to have been fairly taken, this quartz was expected to yield nearly 6 ozs. of gold to the ton; but it has not yielded more, on an average, than 10 dwts. per ton, and the committee fear that the total quantity will not exceed 4,000 tons. Mr. Williams reports that frequent assays of the "tailings" show that practically little or no gold is lost by the gold-dressing machinery sent from England. The machinery to be worked by water power at Brown's Hill was expected to be at work on January 6. Work had been commenced on an hitherto untouched reef, called "Glenister's," from which Mr. Williams had obtained better samples than from any other workings since his arrival. The company possess four other farms besides those on which Brown's Hill and Ophir Hill are situated, which have not yet been thoroughly prospected, and the committee are about to take means to have the reefs alleged to exist upon them, explored. The committee hope to hold the general meeting as soon as replies have been received from Mr. Williams upon some questions raised by the existing circumstances, but this cannot occur earlier than the month of April.

.

THE position which Indian Tea has attained in the London market during the last decade, must be a source of great satisfaction to them who have embarked large capitals in the industry. From the annual circular published by Messrs. Gow and Wilson it appears that between 1874 and 1884 the increase in consumption of that article was just 350 per cent., while there was a corresponding and considerable decline in the deliveries of China teas. The production for export of the latter seems to have reached its highest in 1879, when the speculative rise in prices flooded the market with such an amount of re-dried rubbish as to disgust the London retailers, and this led to increase the popularity of the Indian growth, as Messrs. Gow and Wilson very properly remark that China being a producing and consuming country, there is a temptation for re-drying the leaves once used, and exporting it to foreign countries. But such is not the case in India, where the consumption is limited, and that too not in the producing districts; and there exists no necessity for 'doctoring' the tea. Dealers have realized for themselves the fact that for an equal outlay, Indian has been of far more value for the money than the product of the Celestial land. If any further proof were necessary it will be found in the extension of gardens in this country, and the addition the last year or two of Ceylon tea which has been absorbed as fast as the increase in production has taken place. While this is the bright side of the picture, let us turn to the other, and see what experienced men have to tell us in regard to the modifications which the excellence of Indian tea have gone through, and how far we may take a lesson from the deterioration of China teas. Messrs. Gow and Wilson tell us that of late the managers of the Indian gardens have been too intent on quantity, and consequently care and discretion in manipulation have been disregarded. Ceylon, too, is apparently hastening its production at too rapid a rate, and the course of prices has somewhat reflected this fact. For Indian teas the closing quotations of 1884 are the lowest ever recorded. The same quality of tea

which less than three-and-a-half years ago was saleable at as high as 1s. 6d., is now offered in the market at under a shilling a pound. This does not all result from the events of 1884, though the market has been so seriously depressed by untoward incidents, such as the Oriental Bank failure, and the constant forced sales of the period under review. Dealing with the statistics of 1884, we find that the sales to home consumers have been unprecedentedly large. The average deliveries of each quarter show increases with corresponding periods in 1883, and twice in the year the monthly deliveries were over six million pounds. Consequently, although the arrivals in the calendar year have been some 5½ million pounds more in 1883, the stocks only stand about 2,900,000 lbs. higher than a year ago, and, as teas have been hurried forward in the first half of the season, the arrivals in the second half will be below the figure of the January-June period of 1884.

.

To forecast the possible position of stocks of Indian and Ceylon teas at end of June next, it is necessary to examine the crop estimates for the 1884-5 season, the arrivals to date, and balance to come forward, and the deliveries so far, with an estimate of the consumption for the six months to end of June, 1885, taking note that there is now in London a stock of about 27,000,000 lbs. of Indian and Ceylon tea in warehouse. The crop prospects were placed at a yield of 66,664,000 lbs. in the Indian districts, and as the exports from Ceylon rose from 623,000 lbs. in 1882 to 1,523,000 lbs. in 1883, it may not unreasonably be assumed that not far short of 2,500,000 lbs. will be available from that quarter in the season 1884-5. This makes a total production from the Eastern dependencies of the Crown of 69,164,000 lbs., and striking off, say, 2,664,000 lbs. as consumed in India or exported to other quarters than the United Kingdom, there would be left an available supply of, say 66,500,000 lbs. Of this supply 42,550,000 lbs. have been already received in the six months ended 31st December last, so that approximately, a further 23,950,000 lbs. has to come.

We have arrived at the figure of 23,950,000 lbs. as the probable amount to be received in the current six months, basing the calculation on the crop estimate, as originally put forward by the Indian Tea Association. Adding this to the stock there is in warehouse, we get a total amount of rather over 51,000,000 lbs. to be dealt with. The next point to be considered is that of deliveries. In the half-year to 30th June 1884, the home consumption was 31,424,000 lbs., and the deliveries were especially heavy owing to the fall in prices, the new half-year was commenced with the lowest level of values yet reached, and there is rather the probability of an increase in the deliveries of the first half of 1885, over the same period of 1884, than that deliveries will either be maintained at the quantities of 1884 or will be less. It seems therefore probable that despite an assumed increase in the supply of 1884-5 over the previous crop year of about 3,500,000 lbs., there will not be much more stock at 30th June, 1885, than there was in June last, and there is the probability of the stocks being reduced by smaller arrivals than those estimated, inasmuch as the available supply for the United Kingdom, is, by recent accounts, reduced very much, in fact estimates of 2,000,000 lbs. to 4,000,000 lbs. less than the 66,664,000 lbs. of Indian growth are now current.

INDIAN WHEAT.

It was shown by us a few days ago, that wheat may be successfully grown on the same land year after year, provided it gets a yearly dressing of half a maund of nitre, per bigha. The best time for the application of this dressing is when the young wheat is six or eight inches above the ground. It is necessary to mix the nitre with five or six times its weight of ashes, lime, or other powdery matter, to secure its even distribution, as half-a-maund of nitre is much too small a quantity to be distributed evenly over such an area, by itself. A light shower diffusing the manure over the wheat, immediately after its application, is very beneficial to the crop: but as showery weather can never be depended upon in India, in December or January, irrigation just sufficient to moisten the surface soil, from six to eight inches deep, and no more, is very desirable. Any excess of water acts injuriously, by washing the nitre,

which is a very highly diffusible salt, out of reach of the roots of the wheat.

In England, our farmers ordinarily use ammonium sulphate, or nitrate of soda, for top-dressing their wheat, nitre selling at much too high a price for ordinary agricultural use. Indian agriculture has here a great advantage, as nitre is not only cheap, but can be manufactured by the poorest Indian peasant, if he cares to do so. The old broken down mud-walls that disfigure almost every village, yield ready-made nitre in almost any quantity. We thus require neither retorts, nor furnaces. The ordinary every-day appliances of Indian peasant life, suffice for the purpose. The manufacture of nitre has been practised in many districts of Bengal for centuries, though not for agricultural purposes, and the Indian peasant manufacturing nitre, for export as saltpetre, is one of the common sights in many of our districts.

The presence of nitre in old mud structures makes their crumbling walls, moreover, an admirable powder for mixing with, and increasing the bulk of, the actual nitre used. Our recommendation is not, be it observed, founded on theory alone. Positive experience in wheat-growing, in certain districts of Bengal, has disclosed the fact that our cultivators do use this very material, and as top-dressing, without knowing *why* it succeeds. Any one having much acquaintance with village life in Bengal, will probably have observed the use by the ryot of pulverized old walls as top-dressing for his kitchen garden. As a fact, it is widely practised and well known all over the country. The practical value of nitre in this shape is, we say, well known to the people. It is the scientific use of it that has to be explained, and made familiar to the ryots, to make them take an intelligent interest in the practice, and to further its extension and more systematic use on their lands. Of all common plants, cereals, especially wheat, require the most nitrogen in their food, and they are dependent on the soil for it. It is an apparent paradox of agricultural chemistry, that while the cereals such as wheat, barley, oats, rice, maize, &c., contain only half as much nitrogen in their composition as the leguminous crops—peas, beans, &c., the former require more nitrogen in their growth than the latter. Hence it is, that the cereals derive more advantage from nitrogenous manures, than leguminous crops. The use of ammonium sulphate, or nitrate of soda, as top-dressing for wheat in England, is resorted to only for the nitrogen which they contain, and that nitrogen in the most available form. In the absence of these two chemicals in India, or as they are called, artificial manures, we have ventured to suggest nitre, as the latter seems to be the only form in which nitrogen can be supplied to Indian wheat. We must not be understood to mean for a moment, that farm-yard manure is not good for wheat. On the contrary, it is one of the very best manures at the farmer's command, for all crops whatever, wheat included. Our reason for suggesting nitre instead of farm-yard manure in India is, that the latter can be ill-spared by the peasant, since he has no other fuel; and that nitre has a higher manurial value for wheat, and is applied with more economy of time and capital. Ammonium sulphate and nitrate of soda are known to produce the largest yield of wheat, in the shortest time, and with the least amount of loss, and nitre we think is likely to do the same. As we purpose, however, to take up the whole subject of manures in future issues of this journal, we pass on to the consideration of another question.

The stock assurance of a certain class of writers concerning agricultural progress in India is, that the ryots have nothing to learn from agricultural reformers, and that even if they had, they are too poor to adopt a higher style of farming. Now this is evidently the old and vicious process of moving in a circle.

The poverty is exaggerated, we believe, in so far as many districts of Bengal are concerned, but if we allow that they are very poor, there is the greater reason for an attempt to better their condition. Instead of being resigned to the inefficiency of old methods, which means floating down the stream, the Indian ryot should be urged to make head against it, and to progress. The very writers who move in this same circle, claim for the peasant the credit of perseverance, skill, and strong common sense; and justly. But we require nothing more from the peasantry of India, than the exercise of their strong

common sense, perseverance, and skill. The ryot is not so poor that he cannot invest Rs. 2½ in nitre for a bigha of his wheat land, to reap twice that sum in a few months time. Once made to understand the nature of the investment, he will know where to find the money. Forty years ago, English farmers knew as little of scientific farming as the ryot does to-day. We remember well the opposition which the scientific lecturer used to encounter from the practical, prejudiced, stubborn farmer in the English counties. Where is the opposition now?

CINCHONA PLANTATION.

MR. JOHN HAMILTON who, from his practical experience both in Ceylon and Mining-lane, is an authority on the subject of Cinchona growing, has done good service to those engaged in the industry by the compilation of valuable statistics respecting the production and consumption of bark throughout the world. In a pamphlet just issued he offers some useful advice to Cinchona planters in Ceylon on the subject of bark preparation and selection. He was led to embody his opinion in the form of a book owing to the fact that since Mr. T. C. Owen's work was written, prices have fallen to a point that makes it a matter of considerable importance as to what bark should be harvested at all, and if harvested, whether it would not be best to accept whatever price is obtainable locally in preference to shipping at a loss. Mr. Hamilton also discusses the subject whether more money might not be made out of the low-class bark that is constantly coming forward. When the growing of Cinchona was first taken in hand as a commercial industry, hardly any attempt was made at preparation, for a simple reason, that there was a lack of experience, nor was there any necessity for it, for competition was brisk without it, prices were satisfactory, and the profits to the planters enormous. But things have changed since, and as Mr. Hamilton observes—"The progress made has certainly astonished everyone; for not only has Ceylon become the chief cultivated bark-producing country in the world, as regards quantity, but she is sending into the London markets parcel after parcel of renewed growths, with analyses scarcely conceived in the days of the best South American Calisayas. Just at present the price has fallen a good deal below what we may expect in the future, owing to various causes as unexpected as they are disheartening; but the position of the article is good, and men will do well to learn all they can to make the utmost of the fortunate prize which has fallen into their hands, and which is steadily tiding many on to renewed prosperity, especially if, as it seems probable, the yearly average export of the future is not to be maintained."

The following quotations are some of the practical hints on the subjects under various headings:—There still seems to be much uncertainty regarding the kind of quills required by the trade, and many have suffered both disappointment and loss by sending home renewed quills, young papery quills, quills from varieties undesirable for the purpose, such as calisaya, pubescens and hybrid, which would only be bought off analysis. All these should have been shipped in bales as stem chips. My impression is that it only pays to harvest as quills, original succirubra, from four-and-a-half to five years old at the earliest, and then only from trees of stout growth. The quills should be 2-ft. in length well assorted, and quite even. They should be packed in cases, and care should be taken that no small pieces are inserted to fill up crevices. Good officinalis quills have brought high prices, but I think other ways of harvesting officinalis are more profitable. The tops of the trees, where the bark is naturally weak scarcely pays to harvest as quills, and should, therefore, be broken up into stem chips. Stout, clean, even, well assorted 2-ft. natural succirubra quills always command a good price, but they must be packed carefully to avoid getting broken. The more silvery the better, and the lichen should in no case be removed, as it apparently gives them a traditional value in the eyes of druggists. On no account should renewed barks be shipped as quills.

"CALISAYA.—With one or two exceptions (notably Stellanburg and Penmynydd) this bark is by far the most unprofitable kind grown in Ceylon, and could with advantage be replaced by something else. When harvested, it certainly should not be quilled.

"ORIGINAL SHAVINGS, if not taken from too young trees, seem to realise paying rates. Care should be taken to keep them clean and free from twigs, and parcels should not contain less than 500 lbs.

"RENEWED SHAVINGS.—I have noticed parcels with this designation that have contained as much *natural* as *renewed* bark in them, in addition to twigs and extraneous matter; the analysis naturally corresponding with the sample. On the whole, however, this class of bark is better prepared than any other that comes on the market with the exception of renewed chips.

"ORIGINAL CHIPS.—In these parcels I would suggest more assortment, and the winnowing out of inferior stuff, which lowers the analysis and does not really pay to ship. A large shipment of chips would frequently stand a good deal of picking over before leaving the estate.

"RENEWED CHIPS.—In most cases the preparation of these, both of officialis and succirubra, has been very good. They have evidently been more generally adopted than shavings in the past year, owing to coppicing I conclude, and prices on the whole for this class of bark, have been satisfactory.

"ROOT.—The price for root continually varies. When supplies are heavy, root is the first to fall; if supplies are light, root immediately rises in value. Fine bright succirubra root sells readily, and prices for this description are well maintained. The process of cleaning suggested in Mr. T. C. Owen's work is not always carried out, viz., 'to wash the root in running stream before taking the bark off,' or we should not hear of manufacturers giving up buying root on account of the dirt. It must pay to thoroughly clean root bark, and that is a point worthy of attention in view of the falling off in supplies from Ceylon.

"BRANCH BARK AND MIXINGS.—Both officialis and succirubra mixings, if of fair quality and in good order, are most profitable shipments, yet it is in these parcels especially that the valueless twigs and extraneous matter are so often found. What I describe as 'mixings' generally contain some shavings, both renewed and original, some chips, original mostly, and good stout branch, &c.; eliminate from these the twigs and the rubbish, and you have a very useful parcel. The extra expense and attention to these lots would give a nett result considerably higher than that obtained for most of these shipments at present, and would, I think, well repay both.

"TWIGS.—At present rates it does not pay to ship succirubra twigs, and growers should only harvest them for the local market. Officialis and ledgeriana twigs could be shipped if it is known they contain a good analysis, but it must be borne in mind that a 1 per cent analysis of twigs is not equal to much more than a $\frac{1}{2}$ per cent analysis for other barks, but let them on no account be mixed in with good bark.

"LEDGERIANA.—Very little of this variety has, at present, come on the market. Original shavings, so far, have sold better than renewed, but, perhaps, after the first renewal the analysis may improve, as has been the case with succirubra—the fourth and fifth renewal showing the best results of all.

"QUANTITY.—No assortment should contain a less quantity than 500 lbs., otherwise it runs a chance of not being tested by the buyers. Quills, and very fine lots of renewed barks are an exception to this rule.

"MARKETS.—I think it will be found that careful preparation of Cinchona bark will decidedly command the special notice of buyers towards those marks where such attention is continuously bestowed."

THE DOOMRAON AGRICULTURAL EXHIBITION.

(FROM OUR SPECIAL CORRESPONDENT.)

DOOMRAON, February 19.

NEVER before, in the memory of the eldest inhabitant of the district, has Doomraon worn such a gala appearance as on the present occasion. The elite of the European and Native communities of Behar have come together from distant parts, not with the object solely of joining in a general holiday, but to realise for themselves the material resources of the district, and its productive capabilities. Every department of the Exhibition was as complete as it could possibly be, and it would be invidious to any one for special praise. I cannot, however, pass over

the show of vegetables and flowers without a few words of comment. They are without exception the very best of their kind, and beyond the expectation of the most sanguine in such matters. For country potatoes, Mr. Stalkart and Kursem Bux carried off the 1st and 2nd prizes, respectively. For sweet potatoes (red), the Collector of Bettiah took the first prize, while the Bazar Government Estate walked off with the first prize for yams. Dr. Price and Mr. Inglis divided the prize equally between them for tomatoes. Baboo Hunuman Pershad's exhibition of garden peas, sent all the way from Chunar, carried off the palm. For cauliflower, Mrs. Tweedie got the 1st prize, and Syed Fazl Imam the second. For cabbages, the sub-divisional officer of Sasaram took the 1st prize. The Maharaja of Bhugwanpore and the Maharaja of Doomraon carried off a number of prizes, especially for celery, a dilli of European vegetables, best fruits of the season, a collection of foliage plants in pots, &c., &c. The bouquet of cut flowers, exhibited by Col. Heywood, was particularly good, the Maharaja of Doomraon following suit. For another bouquet of cut flowers, which was also very good, Mrs. Nolan, of Arrah, took the first prize, and Mrs. Tweedie the second. To the latter was also awarded the first prize in floral ornaments, which required to be seen to be admired.

PLOUGH COMPETITION AWARDS.

The following notes recorded by the judges appointed to decide upon the comparative merits of the various ploughs exhibited at the Doomraon Agricultural Exhibition, will be read with interest by all concerned with agricultural improvements. The judges were Mr. W. F. Burrows, (Messrs. Burrows, Thompson and Mylne, zemindars of Behar, Shahabad); Mr. D. J. Macpherson, of Arrah, and the Hon'ble Harbans Sahai, Secretary of the Behar Landholders Association, whose local influence and repute should obtain wide adoption of the ploughs which their judgments have approved.

REPORT.

DOOMRAON, February 20.

It had been intended to conduct, during the Doomraon Exhibition, ploughing matches under conditions which would put to an exact test all the good qualities which each plough, sent to the Exhibition, possessed, but it was found impracticable to proceed with the trials in the strict manner originally intended owing to the want of a sufficient number of uniform yokes of trained bullocks and of ploughmen accustomed to such ploughs. The judges were, however, able to form an opinion of the general character of the work of each by setting it actually to work, but were also guided in their final awards by a consideration of its price, simplicity, reparability, adjustability to different sizes of bullocks and the like, and by the opinions expressed by the cultivators who were present and the men who actually drove the ploughs. The trials took place on the second and fourth days of the show on a light loam, locally known as *danger*, in the presence of a large concourse of peasants. The judges have agreed in awarding the following prizes:—

A. PRIZES, FOR IMPROVED PLOUGHS

1st Prize, Rs. 50.

The Katsar, sent from the Cawnpore Government Farm, price Ra. 6

2nd Prize, Rs. 25.

Avery's Hindustan, No. 1 (exhibited by Messrs. Burrows, Thompson, and Mylne, of Beheer) price Rs. 15

B.—PRIZES, FOR COUNTRY-MADE PLOUGHS.

1st Prize, Rs. 25.

Gavin Jones' Keshikar plough (exhibited by Messrs. Burrows, Thompson and Mylne) price Ra. 7

2nd Prize, Rs. 20.

The Saidapet Government Farm plough (exhibited by Messrs. Burrows, Thompson and Mylne) price Ra. 6

It is worthy of observation that all these ploughs were drawn with apparent ease by a pair of weak bullocks, brought by one of the Nautigunge Government ryots, who asked for them to be tried with the ploughs, thinking that they would prove unable to draw them. The soil, however, as already remarked, was comparatively light.

The object of the matches was not to show the cultivators what individual plough is recommended for their adoption, but to give them an opportunity of seeing what can be done by the addition of a soil-inverting apparatus, and the kind of plough which might in time be modified and simplified to suit the requirements of Indian husbandry.

As two first prizes cannot, by rule, be assigned to the same implement, the first prize for country-made ploughs has been given to the "Keshikar" instead of to the "Katsar."

A wooden "Duplex plough," sent from the Cawnpore Government Farm, failed to invert the soil as effectively as the "kaiser," and had a less convenient form of stilt; but it had the advantage which none of the rest of the soil-inverting ploughs possessed, of having besides the share, with iron mould board, similar to the "kaiser," an ordinary moveable country share which is better adapted for covering the seed furrows than a soil inverting one. This obviates the necessity for the cultivator's keeping two ploughs; and the price which is not marked on the plough is understood to be only Rs. 4-4, in all.

Miscellaneous Items.

THE first batch of emigrants from Madras to British Guiana left Madras last week, for Demerara, by the British ship *Bruce*.

THE Japanese papers state that the total value of the exports from Yokohama for 1884 was 21,416,961 yen, and of imports 19,039,443 yen, making a total of 40,456,404 yen.

THE Lieutenant-Governor and Chief Commissioner, N.-W. P., has directed that oil-seeds imported into the Agra Municipality shall be exempted from payment of octroi, with effect from 1st April, 1885.

THE *Ceylon Observer* says that Mr. D. Mackay has just returned from Perak, and the result of his explorations there, is stated to be the discovery of a large and valuable deposit of tin ore in the land secured by him in conjunction with Mr. G. H. D. Kiplingstone.

THE Revenue of Indian Sea and Land Customs, excluding the Salt revenue, for the first ten months of the current financial year, amounts to Rs. 68,58,000. For the corresponding period last year, the amount was Rs. 81,78,000, and the deficiency shows to what extent trade has fallen off during the year.

A PROPOSAL has been revived for a floating dock at Colombo. The construction of a northern arm for the Colombo harbour from the rocks at Mulwal Point is strongly urged upon the Colonial Government. The work is necessary to stop the erosion of the foreshore at Mutwal, and the wash of salt down the coast into the harbour.

THE late Mr. P. A. S. Sheppard, who died of typhoid fever at Coimbatore at the early age of twenty-one, was the son of Mr. G. P. Sheppard, Bombay Civil Service. He was trained at the Forest School, Nancy, France, and joined the Madras Forest Department in November 1884, as Assistant Conservator of Forests, 3rd grade, and was posted to Coimbatore, where he was very popular.

THE official reports about Mysore are very disheartening. The failure of the past season's rain is causing great scarcity of water all over the province, and grain is selling at famine rates. Already large quantities of *ragi*, the staple product of Mysore, are being imported from Madras. Famine-stricken objects from the agricultural districts are seen in the Bangalore streets. The heat is trying.

M. LAUTH, the superintendent of the porcelain factory at Sevres, is said to have discovered a new porcelain, which is far superior to the famous old Sevres. After ten years' experiment and investigation, he thinks he has produced a porcelain identical with that of China. Not only does it lend itself to artistic decoration, but it takes all kinds of glazes, and surpasses in beauty the colours obtained in China.

THEY had better look out for serious trouble at Thana. The forest rules, or rather the mode of enforcing them on the populace, have very nearly maddened the aboriginal tribes. It is no use telling such people that forests are preserved for their own good. They only know that they are being deprived of what they have had a right to from time immemorial; and they object to being kept out of their natural rights, in fact being starved to death, in order that provision may be made for their grand-children.

THE *Orylon Observer*, in noticing the success of Mr. Walter Keess at the Royal Agricultural College at Cirencester, remarks: "When we were in Madras in December 1877, we had the pleasure of meeting Dr. Keess, a Eurasian gentleman, who by sheer industry has raised himself from a humble station to be head of the Medical College in that town. His sons appear to be following in his footsteps. . . . We believe this is the young gentleman who was spoken of last year as to be the Superintendent of our Agricultural College. We hope this may be realised."

SOUTH African ostriches are laying eggs so abundantly that only a small proportion can be hatched. One gentleman says "that he had 300 eggs lying in his camp last week. Several have been sold on the Graaff-Reinet market for culinary purposes at 9s. per dozen. This ought to bring puddings, pudding and omelettes within the reach of all, for one ostrich egg is, on the average, equal to a dozen hen's eggs. The incubator may be considered exploded. It is known to have filled the camp with Cape chicks of impaired constitutions or deformed bodies; and, now that the rage for buying ostrich chicks at high prices, irrespective of 'antecedents,' is past, the incubator is stowed away with the old lumber."

THE business of importing Australian cattle into Singapore, for the purpose of supplying the Settlement with good beef, is making rapid progress. It will be observed that Mr. McLeod, who is at present the only person engaged in the trade, has received a further supply of bullocks by the *Natal*, and is ready to fulfil all orders that he may be favoured with. Mr. Osborne, who inaugurated this trade, is at present in Australia, but it is possible he may return shortly with some more cattle. Competition is healthy in every business, and there is plenty of room for both of the enterprising caterers.

SOME little time ago, a reference was made to certain cases in the Rawal Pindus Division, in which owners of land had suffered no little inconvenience and even hardship from the operations of the Forest Settlement. The matter has not escaped the notice of Government. Inquiries have been made, with a view to ascertaining whether it would not be possible to provide expropriated owners with lands elsewhere, or to set aside for them some portion of the protected forests; or else to so modify the forest arrangements, as to mitigate the hardships of these expropriations without material injury to forest conservancy.

THE Secretary of State for India has approved of the proposal of the Bombay Government to establish a Veterinary College in Bombay, at a monthly cost of Rs. 1,520, of which amount Rs. 960 and Rs. 300 will be paid as salaries, respectively, to the Superintendent and Assistant Superintendent. It is hoped to get the College and the Hospital attached to it started and in working order by the 1st April next. The Bombay Municipal Corporation have been asked whether they are prepared to bear a share of the expenditure required for the maintenance of the proposed College, and, if so, what contribution they are willing to give.

THE total value of the foreign trade of the province of Sind for the year 1883-84 amounted to Rs. 5,21,31,319, or 34.07 per cent more than the previous year. In the exporting trade, which amounted to Rs. 3,78,59,231, there was also an increase of 18.45 per cent. Thus the aggregate trade of the port of Karachi during the year under report reached Rs. 8,99,90,600, being an increase of 27.02 per cent over that of the previous year. The increase in merchandise amounted to Rs. 16,09,009 and in treasure to Rs. 6,05,074. The total value of stores imported from foreign ports was Rs. 88,676. The exports of Indian products, chiefly food-grains and oil seeds, amounted to Rs. 3,53,62,485. This, it is satisfactory to observe, is an increase of over 110½ lakhs of rupees on the previous year, and is due to the progress of railways in the direction of cotton, grain, and seed producing districts, and to the reduction of railway rates for the carriage of merchandise. The large and increasing export trade has improved the condition of the cultivating and labouring classes, and led to an increase in the import trade also. The trade with the United Kingdom showed an increase of 33.87 per cent.

Selections.

CANE CRUSHING MACHINES.

FROM E. C. OZANNE, Esq., Director of Agriculture, Bombay, to J. NUGENT, Esq., Secretary to Government, Revenue Department, Bombay,—dated, Camp Galag, District Dharwar, 8th January 1885.

SIR,—As desired in Government Resolution No. 3087, dated 15th April 1884, I have the honour to report that I have carried out experimental trials of several cane crushing machines. I have not yet had an opportunity of testing the machines of the Bhadgaon Farm to which Mr. Robertson drew attention, but a copy of this report will be sent to Mr. Stormont, who will be able to compare his results with those now recorded.

2. I have experimented with the following:

- 1.—The ordinary 2-roller wooden mill of the country.
- 2.—An improved 3 roller cast iron mill with iron frame, invented by Mr. Subrao Raoji Chowhan, owner of a cast-iron foundry in Adisar Peth, Poona.
- 3.—The single-squeeze Bihia mill, patented by Messrs. Thompson and Mylne, with two rollers, 8" x 10".
- 4.—The double-squeeze Bihia mill, with two rollers 7" x 8", and one break roll 4½" x 8".

3. The Bihia mills were sent to the Poona Show by the Bombay agents, Messrs. Ewart, Latham and Co., and were accompanied by trained hands from Bihia. The prices of the mills were given by these men at Rs. 165 and 171 respectively, but the prices quoted in the catalogue of the Madras agents, for mills answering the descriptions given, are quoted at Rs. 150 and Rs. 160, respectively. It may be that those I tried were provided with steel pinions, but a reference will be required to clear up the points of difference in quoted prices.

The Bihia mill was tried by Mr. Stormont at Bhadgaon. He reported very unfavourably on it. I believe that the firm have improved on their old pattern, for the results about to be exhibited are decidedly favourable.

The Poona mill, which is a 3 roller mill, has an iron frame, whereas the Bihia mills have a wooden one. The rollers of the latter are slightly grooved. Those of the Poona mill are quite smooth. This latter mill has for some time attracted attention.

extensively used. It is most undoubtedly vastly superior to the wooden *chark*, and has to a great extent superseded it in the close vicinity of Poona, where the makers are at hand to repair the iron mill.

4. The first trial was made during the Poona Show.

Two mills were worked, viz., Subrao's and the Bihia 2-roller.

For the former, two pairs of ordinary bullocks, with a driver for each pair, are required. Two men feed the machine, one inserts the cane between two of the rollers, the other receives the half pressed cane and pushes it back between the middle and third roller. The mill is placed on the ground, and to receive the expressed juice a hole is dug in the ground into which a large iron or earthenware receiver is placed. This is covered over with boards and one of the feeders sits on the boards. The cane is cut into lengths of about two and a-half to three feet, and the cut is made in a slanting direction so as to leave a pointed end for insertion between the rollers. It took a man 15 minutes to prepare 500 lbs. of cane, already topped and stripped. This cutting is quite unnecessary for the Bihia mill.

For the latter, only two oxen are used, working singly at the ends of levers by which motion to the machine is imparted. Two drivers are required, but only one feeder. As there is a contrivance for holding the cane inserted the feeder has ample time to clear away the squeezed cane himself. The machine bites the cane and holds it so that there is no necessity for its being cut into short lengths. In the trial the workers of Subrao's mill kept the bullocks at a pace which they could not have maintained for half a day, the usual time for a set of animals to work. This haste was quite uncalled for. The man in charge of the Bihia mill worked very steadily and deliberately.

Results.

	Subrao's Mill.	Bihia Mill.
Time occupied to squeeze 500 lbs. of topped and stripped cane	63 min.	65 min.
Weight of juice extracted	342 lbs.	308 lbs.
Percentage of juice to cane	68.4	61.6
Number of oxen employed	4	2
Number of men employed	5	3

It must be noticed also that the juice is received from the Bihia mill in pots placed on the ground easily removable. The time occupied in lifting out the juice from the buried receptacle in the Poona mill is considerable. Fully two men more are required by this latter mill.

This result was considered unsatisfactory by the man in charge of the Bihia mill, and as considerable interest was excited by the trial it was decided to repeat it. An *insandar* offered the use of his land and cane, and to provide labour.

The second trial was made after the bustle of the Show was over. Four mills were used;—

1.—The wooden country mill, worked by two pairs of oxen with drivers, two feeders, and one helper. The cane has to be cut into short lengths. A large hole is dug, large enough to admit the two feeders. The bullocks assigned to this mill were the best on the ground. The pairs assigned to the Poona iron mill came next in quality. Those given to the Bihia mills were certainly inferior, but they were quite good enough.

2.—Subrao's mill.

3.—Bihia single-squeeze mill.

4.—Bihia double-squeeze mill.

This last only requires one bullock, one man to drive, and one feeder. In other respects it has the same advantages as the single-squeeze mill above described.

The trial was made very carefully under ample supervision, for I was assisted by a European and a native gentleman to watch each mill and to weigh and distribute the cane, and finally to weigh the expressed juice.

500 lbs. of cane, topped and stripped and cut into lengths for the two first named mills, were distributed.

Results.

	No. 1.	No. 2.	No. 3.	No. 4.
Time ...	67 min.	48 min.	69 min.	103 min.
Weight of juice	338 lbs.	337 lbs.	346 lbs.	353 lbs.
Percentage of juice to cane	67.6	67.4	69.3	70.7
Number of oxen	4	4	2	1
Do. of men	5	5	3	2

The pace at which the cattle worked was tested with the following result:—

Number 1	3½ rounds per minute.
Do. 2	3 do.
Do. 3	2½ do.
Do. 4	2½ do.

I had no dynamometer and resorted to a rough method of comparing the power expended on each mill. I found that the ordinary labourer pulled about 60 lbs., measured by a spring balance. The following numbers of men were needed to turn each machine:—

Number 1	7 men (representing 420 lbs.)
Do. 2	5 do. do. 300 "
Do. 3	2½ do. do. 150 "
Do. 4	1½ do. do. 75 "

I must note that owing to haste and hurry on the part of the feeders of No. 2 mill (Subrao's), some juice was spilled in changing the pots. On the whole, I thought, that as to the quantity of juice, Nos. 2 and 3 were about equal.

Mr. Subrao claimed another trial on the ground that his mill could do better work than this. Another field had to be chosen. Here the cane was seventeen months old (that of the principal trial was only one year old). I succeeded in having No. 4 Bihia

mill (3 roller) brought to the spot, but the expert had gone. It was led by a new hand. The results were—

	Time.	Juice.	Percentage.
Subrao's Mill	60 min.	365½	73.1
Bihia 3-roller	130 min.	322	64.4

In this trial I weighed the refuse cane, which was found to be 138 lbs. and 165 lbs., respectively.

In the case of the Poona mill 365½ lbs. juice and 138 lbs. refuse = 503½ lbs. The small discrepancy was due to not very accurate scales. In the case of the other mill 322 lbs. juice and 165 lbs. refuse = 487 lbs. Here the discrepancy was too high. I cannot be sure that some of the cane or juice was dishonestly abstracted, but I cannot consider this trial to have been a fair one to the Bihia mill. The feeder was unaccustomed to it. I cannot be certain that it was set properly. However the result was favourable to the Poona mill.

To sum up.—The Bihia mill, as regards portability, cost of setting up, and cost of working, possesses very great advantages over the Poona mill. It is cheaper, though as noted above, the prices are not exactly known.

As regards construction, the trial could not prove much.

In point of mechanism, the Bihia mill shows best.

The efficiency of the Bihia mill is as great as, if not greater than that of the Poona mill. Mr. Subrao deserves very great credit for his improvement. He admits that at first his rollers showed a tendency to break, but claims that they do not now. The wooden *charat* is a thing of the past, where sugarcane-growers have the power to purchase either of the improved mills, or facilities for hiring. This latter is the almost universal practice near Poona.

It is open to Messrs. Thompson and Mylne to introduce their mills into Poona, and I would throw out a hint that they would benefit by making Mr. Subrao their agent, and, if his foundry is good enough, their local manufacturer. The firm of Richardson and Cruddas, in Bombay, now makes the rollers and iron work. This is their affair, not mine. I do not know how far Mr. Subrao would approve of the idea. Mr. Subrao charges Rs. 200 for his mill, but hires it for Rs. 1 a day, bearing all risks. The wooden country mill costs Rs. 35 to Rs. 40, lasts about two years, and is hired for 12 as. a day.

THE PAPER TRADE IN LANCASHIRE.

THE information which reaches us shows that the strong competition now going on all over the country is affecting the paper trade in Lancashire, but that there are signs of the struggle being continued. The *Darwen News* of the 3rd instant says:—The paper trade is a business sometimes regarded as a sort of industrial elysium, subject only to slow and almost imperceptible changes as compared with the sudden fluctuations to which the cotton trade, for instance, is liable. Such impressions no doubt were justifiable in times gone by, but they are no longer applicable to this trade at all. It is now conducted with as much vigour and energy as any other trade, and as a matter of fact, these have degenerated into a competition which is as fierce and deplorable as that existing in any of the staple trades of the country. In grocery and parceling papers generally, there has been a further reduction of prices; to some extent this has been covered by the lower cost of the materials used, so that the paper-maker engaged in this branch is in about the same position as he was a year ago. True, there is not anything like the margin for him there was several years ago, but still by careful management and economising at every possible point, a moderate profit can still be earned. It is not so with those engaged in the manufacture of ordinary printing papers; there is not sufficient demand to keep the machinery going, and there is, therefore, a furious struggle to get business almost irrespective of price. Machinery for producing this class has been erected at a rapid rate during the past few years, because as this was once the best division in the paper trade, it attracted the attention of capitalists who have devoted themselves to its development, until now the production has altogether outrun the consumption. There appears to be no relief from this state of things except by stoppage of machinery or combined curtailment of production. Whether this will be accomplished by mutual agreement or by the extermination of individual mills lies hidden amongst the secrets of the coming year. It is very fortunate for the paper maker that the materials which he uses have again been cheaper during the past year. Every reduction has been instantly given away in the price of paper, and each paper-maker has hurried into the market with the object of winning a little business by the reduction which he was able to make. This was a safe policy. However, during the closing weeks of the year, the trade has been slackener than usual, and the mills have ignored such prudent considerations as usually guide them, and have offered substantial reductions on the manufactured article without either having secured or being in sight of any reduction in the cost of making. Speaking generally, the prospects of the year which we are now entering are anything but cheerful for the ordinary printing paper-makers. The district of which Darwen forms the centre has grown in importance during the past year by the increased weight of paper it can produce, and it now exerts a powerful influence on this industry. We learn that at Spring Vale Paper Works there has been a large evaporating or incinerating house erected for which Messrs. J. O'Neil and Sons have had the contract, and a mill chimney for which Messrs. Lloyd and Mearns have had the contract. The chimney is 104 yards in height, and has cost £2,000. Messrs. Goulburn have in hand a huge contract for the Darwen Paper Mill Company which has kept them well employed, and Messrs. Shorrocks are doing just a fair trade.—*Paper-Maker's Monthly Journal*.

FORECAST OF THE LINSEED CROP OF THE HYDERABAD ASSIGNED DISTRICTS FOR THE SEASON 1884-85.

DISTRICTS.	Percentage by which area under linseed exceeds (+) or falls short of (-) that of previous year.	EXPLANATION.	Estimated outturn in annas per rupee.	REASONS FOR ESTIMATES.
Amraoti ...	+103.2	Cotton and <i>jowari</i> crops having been damaged by excessive rain were root- ed up and linseed substituted, it being a more profitable crop.	13 annas.	Unusually favourable rain for the crop.
Akola ...	+211.8	Owing to excessive rain much of <i>khurif</i> crops had to be removed; the land thus available was sown with linseed. High price also is one of the reasons for the increase.	11 "	The crop is very flourishing, except in Akot and Khamgaon Taluks, where it received slight injury owing to rainfall in December.
Ellichpore ...	+202.6	High price of linseed in the market also partial failure of cotton.	10 "	Seasonableness of rainfall, except the late rains which will cause some injury.
Buldana ...	+76.9	Rotation of crops. Cultivation of linseed in the waste lands newly broken up. High price of linseed.	10 "	Recent rainfall will probably reduce the outturn of the crop to 10 annas.
Wun ...	+14.8	Owing to excessive rainfall, land pre- pared for <i>khurif</i> was sown with lin- seed for which there is great demand.	11 "	Owing to excessive and irregular rainfall, less than an average crop is anticipated.
Basim ...	+160.3	Unseasonable rain for <i>khurif</i> crop in- duced the cultivators to sow linseed where <i>khurif</i> crop was sown last year. Greater demand for exporta- tion, also high price in the market.	9 "	Decrease in outturn is anticipated from the unseasonable rainfall in December last.

OUT-DOOR FRUIT FOR THE MILLION.*

We have received through the kindness of Colonel Wace, Commissioner of Agriculture in the Punjab, a copy of this little pamphlet, which we have already referred to in a previous number of the *Indian Forester*. The author, whose name is not given, but who styles himself "Head Gardener," has experimented on fruit culture in his own property near Bala, in Wales, for the last 20 years, having originally planted a choice and varied assortment of fruit trees, which in three years' time commended bearing, and since then has borne annually increasing crops in the most surprising and prolific manner. As an example of this, in 1875, "Head Gardener" himself hand-picked three trees with the following results:—The first, a dessert pear of excellent flavour, nailed to a wall 7 feet high, yielded 704 marketable pears. The second, also a pear, yielded 744, and as this fruit was of the preserving order, very large and solid, the crop filled four huge baskets, each one a load sufficient for an average man to lift and carry. From the third tree, an espalier apple, of very moderate size, 700 choice russets were gathered, leaving behind some seven or eight dozen below a regular marketable standard. Thus, from three young and comparatively small trees, no less than 2,152 count of good, sound keeping fruit was gathered, and as there were some 25 distinct varieties of pear trees in the garden—all fairly well loaded, according to their respective sizes, and weight of fruit—for instance, one of them, of no great size, whose fruit had easily been forced up to a pound in weight, yielded upwards of 400—the general crop may in some degree be imagined."

The fruit grown consisted of choice varieties of Apples and Pears, Peaches, Apricots, Plums, fruits of the Magnum Bonum going up to a quarter pound in weight, Strawberries, Currants and Gooseberries. Black and White Grapes, and other tender fruit were grown under glass with similar success.

Head Gardener states that whatever blight destroyed or partially destroyed the fruit prospects of the neighbourhood and country at large, never once affected his trees, which his system rendered independent of local conditions.

The scientific explanation Head Gardener gives of his success cannot however be entirely accepted by us, and we should recommend him to study Sachs's *Vegetable Physiology*, though we fully believe in the practical results which will follow a course of treatment similar to his own in the culture of Mangoes, Oranges, Strawberries and Vines, and the other fruit trees and plants which thrive in India. We have indeed experimented with an Orange tree in Dehra Dun, and obtained 10 dozen very sweet oranges from it this year, whilst in former years the fruit invariably fell to the ground without ripening.

Head Gardener states that a fruit tree has three sets of roots—

"Firstly, a mass of fibres, that cluster around its stem, and are solely for fruit-bearing purposes.

"Secondly, a lot of lateral roots, which travel long distances in search of food for wood formation, and out-balance the fruit fibres which remain closely packed at home, the consequence being, if their growth be unchecked, much wood and little fruit. Hence

arises the necessity for closely pruning the wood roots, an operation which restores at once supremacy to the fruit fibres, when much fruit and little wood become the order of the day.

"Thirdly, the tap root, striking downwards to give stability to the tree against winds and storms. Some gardeners, however, consider it a feeder, and prune it when practicable, and to render it so, plant young trees upon slabs of stone, slate or other hard material, which prevent, of course, the tap root from striking downwards." Head Gardener, however, after protracted experiments, has decided that pruning the tap root of fruit trees neither checks the undue growth in a tree's wood, or increases its fruit supply, and that from its large size, toughness, and tendency to grow perpendicularly downwards, deep into clay, gravel, and other crumbly subsoil, where only poor nourishment can be obtained, that its principal or perhaps sole object is to strengthen trees against winds, and that it is a great mistake to prune or mangle with it.

As regards interference with the tap root, we are inclined to agree with Head Gardener, but besides the utility of the tap root as an anchor against storms, it is evident that in the drier parts of India, the great length of the tap root in the jand (*Prosopis spicigera*) and the sal, frequently exceeding 80 feet, solely enables the tree to obtain a supply of water during the dry season, unless artificially irrigated.

Of course in orchards where a supply of water is generally available, this use of the tap root is not of such vital importance as in the case of forest grown trees in the Punjab Rakhia, where the water-bearing strata, during the dry season, is at a very great depth below the surface of the ground.

The mass of fibres, which Head Gardener calls fruit fibres, are of course merely rootlets bearing ordinary root fibres, and it is evidently a great object to obtain a large mass of such fibres near the stem of the tree, so that manure and water may be readily and economically supplied to them, as root fibres are the sole absorbers of nutriment from the soil.

The lateral roots, of which Head Gardener complains, also have root fibres near their extremities, and on their own rootlets, and are really sent out by the plant in search of nourishment, and wander further the poorer and drier the soil may be, but these lateral roots have no real power of nourishing the woody growth of the tree, at the expense of its fruit. They, as well as the woody tap roots, consist of conducting tissue, through which nutriment absorbed by the root fibres or feeders is conveyed to the stem, and thence through the branches and twigs to the leaves and buds.

The fact is that, every tree in a natural state tends to form as large a crown as possible before fruiting, and that premature injury of every kind to its organs of nutrition, such as a season of drought, root or leaf pruning, generally hastens the formation of fruit bud instead of foliage buds. As soon as fruit buds have been formed, a supply of strong manure should be afforded to mature the fruit.

By a liberal supply of rich manure to the rootlets near the stem, these increase greatly in number and become densely covered with root fibres, so that the plant is enabled to take up quantities of nourishment in the simplest manner.

Fruit culture is thus seen to be an extremely artificial method of favoring the crop of fruit at the expense of the crown of the tree, which is only allowed to develop sufficiently to hold the greatest possible mass of fruit the tree can be made to yield annually. Having pointed out Head Gardener's misconception of the relation of the lateral roots and root fibres, we will now follow him, as regards the practical methods for securing a large and constant annual fruit supply. He root-pruned his trees every second year or so, in

* Outdoor Fruit for the Million: how to grow it in large and continuous quantity by simple and inexpensive means. Fifth and authorised edition, revised and illustrated by Head Gardener. London: F. Pittman, 20, Paternoster-row, and Nichols & Co., 29, Oxford-street, 1883. Price, 6d.

following manner :—A young non-bearing tree, which was throwing out wood strongly, was pruned by a sharp spade thrust deeply into the ground a clear foot or so from the stem. In a few years' time the lateral roots again become troublesome, when a narrow trench should be dug around the tree, 18 inches or so from the stem, and the lateral roots bared and severed, the greatest care being taken not to injure the rootlets and root fibres near the stem.

The appreciation of the distance at which lateral roots should be pruned, is the only little difficulty about root pruning, but distances of 3, 4, 5, and 6 feet would take in standards and trees of considerable size, the best plan probably being, though Head Gardener does not say so, to prune off lateral roots at a distance from the stem equal to the spread of the crown of the fruit tree after it has been properly pruned.

The main object of root pruning is to weaken the vegetative vigour of the tree, and it should be remembered, that mere branch pruning will not do this as we see in the case of pollards, the crowns of which are replaced rapidly by strong vigorous shoots, so that after we have thinned out the crown so as to admit light and heat to the fruit, we must reduce the area of the roots, or we shall only have been treating our fruit tree as if we wished it to become a pollard.

The best time for root pruning is said by Head Gardener to be November and December, but Indian gardeners should remember that Oranges are frequently not perfectly ripe till January, and that Lokwats blossom at the end of the monsoon, whilst the fruit does not ripen till April and May, so that the time of operating should be intermediate between the fruit harvest and the blossoming and will be at different periods of the year for different fruit trees.

The method of manuring is thus given by Head Gardener, and should be followed exactly :—

"1. Loosen carefully and draw down the few inches of top soil that cover the fruit fibre space. Then dress liberally with good solid manure, not old weather-beaten stuff with but little nourishment in it.

"2. Put the top soil previously drawn down, mix with a spade-ful or so of fresh, or moderately fresh, lime, on the manure. The tree will then be well nourished for the winter months and prepared for spring blooming."

As regards blights, Head Gardener recommends quick-lime wash applied with a brush to the stems and large branches of fruit trees every third year or so, but he very rightly points out that many supposed causes of blight are due to the exhaustion of the tree in throwing out masses of bloom, when a proper supply of food, in the form of manure, has not been given, so that starvation, and not blight or frost, is as a rule the cause of the failure.

As soon therefore as Head Gardener's trees showed for bloom, pails of diluted liquid manure were given occasionally, as long as the blooming process lasted, and after the fruit had set, the trees were supplied once a week with this liquid, this extra feeding enlarging the fruit, improving its flavour, and enabling the trees to crop heavily without exhaustion.

The manures used were :—

1st. Drainings of the stable and cow-house, which should have pukka floors properly drained into a reservoir, so that none of this valuable manure may be lost.

2nd. Fresh solid manure of any kind well mixed with water.

3rd. Guano; a few handfuls of this, well stirred up, in a pailful of water, is highly nutritious and easily managed. As regards the labour of manuring, it was found that one man could attend to all Head Gardener's trees in about two hours.

In India, if solid bath room refuse be placed in trenches, and liquid refuse in large pails, for 6 months, with the addition of a few handfuls of lime, it may be readily used for fruit culture, and without any unpleasant odour arising. The sweeper will of course supply the manure after the mull has trenched the plants with a small fork so as to avoid injuring the feeding roots.

Head Gardener states that—"under this culture, the trees soon covered themselves with fruit spurs and buds, which in spring threw out masses of bloom, and which, later on in the summer and autumn, yielded masses of fruit; and also, so vigorous did the trees become that they often bloomed a second, and even a third time, and fruit has ripened in favourable years from the second blooming.

All fresh shoots, as the season advanced, were rigorously tipped off, leaving only a sufficiency to fill up gaps or for the gradual extension of the tree, and all leaves covering the fruit were unfailingly removed.

Regarding strawberries, which grow very fairly in all Indian districts at the foot of the Himalayas, the following remarks are very useful :—

"The strawberry plant is one that goes greatly to root and leaf in the soft friable soil of the garden, and bears but poorly in consequence. This plant cannot, like a tree, be root-pruned, and a most successful method of treating it was the following, viz. :—In a dry time, tramp the plot of ground intended for the strawberry bed as hard, if possible, as a beaten road.

"For (1) soil so hardened checks excess in root growth.

"(2). It retains moisture much longer than loose soil does, an important consideration this for the strawberry plant, whose great natural want is water in abundance.

"(3). Woods grow both small and slowly in hard ground, and therefore can be more easily kept well under. Next, line out a well-tramped ground in rows 2 feet apart, and in these dig moderate sized holes also 2 feet apart from each other. Then fill these holes with good manure, and next put into each of them three young strawberry plants (as far apart from each other as the limited space will permit) to form a clump. This finish planting with the soil previously dug out, mixed with lime. The only ground required to be occasionally stirred

(a long-handled spade being the best tool for the purpose) is that within two or three inches immediately round each clump, as by so doing roots gain air, and liquid manure is better absorbed. Then, before winter sets in, say, early in November, put pats of manure over the said clumps, leaving the hard ground round them perfectly bare. This protects the plants from frost, concentrates food where needed, and stops much indiscriminate waste of manure. Then in spring give the plants some good liquid now and then (say once a week) until the fruit sets. The result will be fruit rich in colour, fine in flavour, and great in abundance. By this method of cultivation, strawberry plants throw out large numbers of unusually fine runners, which must be nipped off as soon as they appear, to prevent the plants from exhausting themselves, except, of course, those required for purposes of propagation."

Head Gardener gives several instances in which, by his treatment, old and non-bearing orchards were made to yield as well as his own, and lest cavillers might say that his trees were located in some warm, well-sheltered, good climatic spot, he tells us that his land is in the very heart of the Bala mountains, where the weather is the reverse of pickled, so much so that people thought it too precarious for the growth of fruit.

A remark of Head Gardener's regarding blight must be recorded, it is that "perfectly healthy vegetation grows too fast and exhales strong natural essences which render it an unfitting abode for a pest that only thrives by stagnation and decay; and that blight only fastens on a plant which has been weakened by being deprived of some great natural want or other." We should say that blight is induced by the decomposition of the sap due to the excessive formation of certain chemical ferments in the languishing plant. The theory of the exhalation of strong natural essences cannot be supported for a moment.

Head Gardener gives a useful plan for growing potatoes by placing the sets in rows upon the surface of the ground, and after scattering a little lime over them, covering them first with manure, and then earthening them over with soil. They are dressed with liquid manure after a few weeks, and Head Gardener maintains that by this method, the tubers are properly nourished and protected from excessive moisture of the soil, which is the usual cause of potato disease.

Head Gardener denies, but in this facts and science do not agree with him, that too much manure can be possibly given, as instead of gorging themselves with over-abundant food, as some animals do, plants only take what is actually required for their immediate wants. In order to avoid waste of manure, he advocates that the household slops should be poured on to the manure heap, and that half a forkful of solid manure mixed up with water in a pail and well stirred should be used.

Regarding branch pruning, Head Gardener says :—

"The following system of branch pruning has been found by Head Gardener to be very easy to do, and very effective when done :—

"1. Clear away all dead or diseased wood about the tree.

"2. Prune or saw off all large and superabundant branch-wood, as each branch ought to have full play for itself without being rubbed against, and so damaged by another.

"3. So prune that branches balance well with each other—for then a tree grows gracefully, blooms uniformly, bears better, and is always an object pleasant to the sight.

"4. Prune a standard so that it be, as nearly as possible, hollow in its centre. Sun and air can then penetrate its foliage, and thoroughly ripen its fruit. Besides, the centre wood very seldom bears, and is, therefore, waste.

"5. Prune away all last year's superabundant new shoots—not level with their branch-wood—but so that one or two eyes or buds be left on them, because these eyes or buds will by-and-by throw out fruit spurs, which, of course, will greatly increase the crop. Now wood shoots left for the gradual extension of the tree prune or stop down to eight or ten eyes.

"Now the stopping or pruning down forces branches to throw out additional fruit spurs, so that in time a tree becomes literally covered with them. Fruit then follows in great abundance. Fruit expands and all kinds of fruit trees so that their branch-wood, after the operation, appears to the eye rather thin than not, as overmuch wood means always but very little fruit."

As we have said before, Head Gardener's theory about fruit fibres is quite fanciful, and the diagrams with which the pamphlet closes are misleading, but we owe him our best thanks for publishing the little handbook which gives the results of his experience, and the practical advice in which can be followed with the best results.

We may note here that Mr. Ollenbach, of Dehra Dun, has grown oranges and grapes according to the same system for several years, and that there were 600 oranges last year on quite a small tree in his garden.—*Indian Forester*.

CULTIVATION OF THE KOLA NUT.

To Sierra Leone, so far as we are aware, belongs the credit of having started the first organised scheme for the cultivation of the kola nut on a commercial scale. Plants have been sent to Ceylon and Southern India by Mr. T. Christy, and introduced into the public gardens in India and Ceylon, and here and there private growers are making experiments with them, but we feel sure that we shall be within the mark if we say that it would be impossible to find as many as an acre regularly planted up with this product in either of the countries named. There are, of course, obvious and sufficient reasons for this, and also for the fact that Sierra Leone should lead the van, because the tree is indigenous to the forests of that colony, and there is already a trade in the nut there. We are not surprised, therefore, to learn from one of the local papers that an effort is being made to form a Joint Kola Company, under the title of the "Kola Nut Planting and

THE INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA :—SATURDAY, MARCH 7, 1885.

[No. 10.]

Crop and Weather Report.

[FOR THE WEEK ENDING THE 25TH FEBRUARY, 1885.]

General Remarks.—Rain has fallen during the week in parts of Bengal and in Assam, in two districts of the Madras Presidency, in Coorg, in two places in the Punjab, in Nagpore, in the Central Provinces, and in Tavoy in British Burmah. Except in Bengal and Coorg, the fall generally has been too slight to affect agricultural operations.

There is no change in the agricultural situation in Madras, but in Mysore unfavourable reports are being received from the districts of crops withering from want of rain. In Coorg the recent rain, if followed soon by more showers, will be favourable for coffee. Rice threshing is completed. In Bombay rabi is being cut in most districts, and the harvest promises generally good. In the Berars, Hyderabad, Central India States, Ajpootana the rabi promises well. In Manipore (Bhopawar) age has been caused to poppy, linseed, and gram crops. In the Punjab agricultural prospects continue generally satisfactory, and this is true also of the North-Western Provinces and Oudh, though in some districts the crops have been injured by blight and insects. The rabi in the Central Provinces, and prospects are favourable.

In Bengal prospects are unchanged. The late rain has been beneficial for paddy, but has impeded the threshing of paddy which was in several districts. Ploughing for *aku* in Assam, where also the gathering of mustard.

Cholera is present in several districts in Madras, but is abating. Small-pox present in Coorg, the Central Provinces, North-Western Provinces and Oudh, and Bengal.

Prices are generally steady, except in three districts in the Punjab.

Madras.—General prospects fair, except in parts of Bellary and Anantapore.

Bombay.—Rabi harvest commenced in parts of Surat, Ahmedabad, and Kaladgi; in progress in other districts; scarcity of fodder and drinking water continues in several talukas of the Southern Mahratta Country districts; cholera in parts of 8 districts, cattle-disease in parts of 6, small-pox in parts of 10, and fever in parts of 15 districts.

Bengal.—More or less rain fell in some of the districts of the Province. It has generally benefitted standing crops, and facilitated the ploughing of lands for the early crops. Harvesting of rabi crops is going on. The late rain has impeded the threshing of paddy which has commenced in several districts; prices of food-grains on the whole stationary; cholera and small-pox are still reported, otherwise general health good.

N.W. P. & Oudh.—No rain during the week; weather generally seasonable, in some places cloudy and warm; crops damaged by blight and insects in some districts, otherwise prospects good; prices steady on the whole, and markets well supplied; general health good; a few cases of small-pox reported in Cawnpore and Kumaon; cattle-disease continues in Kumaon.

Punjab.—Health and crop prospects good; prices rising in Hissar, falling in Delhi and Peshawar, and stationary in other districts of the province.

Central Provinces.—Weather clear and cool; prospects generally favourable; rabi crops being harvested; small-pox in places; cholera reported from Nimar and Sumbulpore; prices steady in Nagpore.

British Burmah.—Cholera more or less prevalent in parts of Akyab, Proma, Thongwa, and Hensada districts, but not severe; small-pox prevalent in towns of Hensada and Thayetmayo and in three townships of Mergui district; slight cattle-disease in Hantawaddy and Bassein, otherwise public health and health of cattle good.

Assam.—Mornings and nights cool; mustard being gathered; ploughing operations for *aku* in progress; but rain wanted to facilitate them; public health fair. State and prospects of crops as last week.

Mysore and Coorg.—Increasing unfavourable reports received from the districts, of crops withering for want of rain; cattle generally

falling off in condition; water-supply diminishing; public health fair; prices show little change.

Berar & Hyderabad.—Weather clear; cotton-picking almost completed; rabi crops in good condition; wheat 23 and jowari 26 seers per rupee; threshing of *kharij* completed; harvesting of rabi commenced; general health fair.

Central India States.—Weather clear; prospects of rabi favourable; prices steady; health good.

Rajpootana.—Weather seasonable; crop prospects favourable; prices stationary; health good.

Editorial Notes.

WE see that the Conservator of Forests has invited tenders for the purchase of the right in the Thanna district to collect mowra flowers growing in all Government forests, whether protected or reserved, in alienated villages, in Government waste lands and village sites, and in the occupied lands of villages in the Dahau, and Mohun Wada, and Sholapore talookas coming under the Dahau and Kolwan settlements. In cases where there is a dispute as to the right of Government to mowra flowers, the decision of the Collector is binding. The contract is to run from the 6th of March to the end of the current year. The notification does not say how far the rights of the tribes, who have collected mowra flowers from time immemorial, will be respected under the arrangements proposed. These tribes earn a precarious livelihood by the produce of the forests, and if their rights are interfered with, the consequences may be lamentable not only to themselves but also to the employes of the contractor. It would therefore be desirable that matters be smoothed in the beginning to prevent a conflict between public and private right.

.

WHILE on this subject we may as well mention here that at a meeting held the other day in the Bombay Presidency, Dr. Fairbank spoke about an important little scheme which he hoped would tend in a great measure to ameliorate the condition of the Ahmednugger peasantry as also of the so-called criminal classes, the Shudras and Ati-Shudras. As is well known every district of India possesses certain communities—Mahurs, Mangs, Bhils, Gonds, and others, who apparently have no ostensible means of livelihood. In days gone by when the Forest and Abkari laws were unknown to the people, and when the revenue system together with its working had no scientific basis underlying its principles, these outcasts of humanity barely managed to eke out a miserable existence. Now it is impossible for them to do so when *kunbis* are unable to earn a living by the sweat of their brow. The latter, in a state of impoverishment, give up tilling land, and the former driven to desperation, have taken to lifting cattle, or destroying them by poison for the sake of the hides. Dr. Fairbank therefore proposed that, as has already been done in several instances, through his instrumentality, some of the Bombay capitalists might invest their money in Ahmednugger land, either buying out the owners or advancing loans at a reasonable rate of interest. The gentlemen present were favourably impressed by the idea, and although in the beginning there would be difficulties in the way of practical success, yet eventually it would prove a fair speculation. In honor of Mr. and Mrs. Birdwood who were present on the occasion, it was resolved to name the first farm opened in Ahmednugger the Birdwood Farm.

NOTWITHSTANDING the efforts that are being made to promote among the rulers an intimate knowledge of the arts and manufactures current among the people of India, we are yet a long way behind the needs and requirements of the times. The collection of exhibits sent to the Calcutta Exhibition, by the Government of the North-Western Provinces, has brought to notice several handicrafts which had hitherto escaped observation, and has otherwise enlarged the previously existing knowledge of others with which we are unacquainted. The following *resumé* of the art industry of the Bulandshahr District, by Mr. F. S. Growse, C.I.E., will be found highly interesting:—In the Bulandshahr district there are a large number of skilful wood carvers, chiefly in the towns of Sikandarabad, Bulandshahr and Shikarpore, though others almost as good may often be found in quite small villages. The art is mostly employed upon doors, door-panes, and shop-fronts. One pair of doors (made for the Bulandshahr Town Hall) won a prize in Calcutta; another pair is in the South Kensington Museum, and a third has been made for the Indian Institute at Oxford. The difficulty in the way of creating an export trade lies in the insufficient supply of properly-seasoned *shisham* wood. A good workman gets from Rs. 10 to Rs. 15 a month. The cotton-prints of Jahangirabad are of good and varied design. They have won prizes at Jeypore and Calcutta. By natives they are chiefly used as counterpanes (*palung-poshes*), but they will also do for table-covers, and, as now adopted, make very effective curtains. The cost of a pair of curtains, each 11 feet 6 inches by 6 feet, and lined with similar materials of a plainer stamp, is Rs. 12. The manufacture is confined to one family, which, however, is a numerous one. They are now executing a large order for Messrs. Holme & Co., of Farringdon-road, London. The muslins of Sikandarabad are a local manufacture of long standing. The quality is fine, and the *pagris* and *dopattas* are highly esteemed by the rich native gentry; but the prices are too high for any large general sale. About 12 families are employed in the trade. Jewar has long been noted for its cotton rugs, a blue design on a white ground, and for its *darries*, which are more like what is generally called a *khes*. Woollen rugs are now also made; of good design, medium fineness, and reasonable price, a rug, 6½ feet by 4 feet, costing Rs. 16. The price of a cotton rug about the same size is Rs. 8; a *darri*, 5 feet 9 inches by 3½ feet, Rs. 3-8-0 or Rs. 4, according to the pattern. About 10 men are employed. The only maker of the Khurja pottery is a man by name Abdul Majid, who is now also teaching his brother. His special colours are peacock blue and cinnamon. Large jars of these colours combined, two feet high, are very handsome, and cost only Rs. 3 each. Messrs. Holme and Co.'s agent was willing to take all the man could supply; but I could not spare him any, having more orders than could be executed for people here in India. The maker can turn out about Rs. 50 worth in a month, and whatever he makes is sold at once. He takes an artistic pleasure in his work, for each successive batch is an improvement on its predecessor; but he is apparently quite indifferent to developing a large business.

.

THE following paragraphs are taken from a note by Major D. Pitcher on the artistic handicrafts of the United Provinces:—Heretofore the Rampore State had been chiefly known, so far as art products are concerned, as the seat of a manufacture of blue and white pottery; but the enquiries for the Exhibition revealed that his Highness is a liberal patron of art, maintaining in regular pay silversmiths, workers in electro-plate, armourers, and Cashmiri artists in painting and illumination. Embroidery also on cotton damask, locally called *khes*, and weaving of *khes*, flourish greatly under his Highness's patronage, and apparently a considerable trade exists. The excellence of the arms fashioned here is very remarkable, as is also that of some minor steel manufactures, such as wires for musical instruments, and fish-hooks, the latter equal to those of English manufacture. The pottery manufacture shows decided signs of improvement, and instead of being confined to simple blue and white, as reported last year, other colours are now attempted with success. His Highness the Maharaja of Benares is likewise a patron of art, maintains in his employ artists highly skilled in ivory carving, enamelling on gold, photography, &c., besides patronis-

ing in his estates settlements of weavers of Persian carpets. The carpets generally known as Mirzapore carpets are, it is believed, mostly woven on the Maharaja's estates. In addition to the engraved brass-ware so well known, a great deal of not less artistic, but not perhaps so well known, repoussé work in brass is carried on at Benares. Silk fabrics and *kinkhabs* were mentioned last year. The exhibits of these shown at Calcutta, both in the provincial court and in the jewel-room, evidenced that the trade is in a flourishing condition. Gold and silver lace may be added to this category, as amongst Benares specialities.

.

MUSICAL instruments are made in many towns, Rampore, Lucknow, Benares, &c., but Benares appears to be the chief seat of the industry, which admits of much ingenuity and of artistic taste. In a *sitar* from Lucknow, for instance, the body of the instrument was formed from an ostrich egg. Though confined to but one or two artists, mention may be made of the beautiful paintings on ivory procurable at Benares; in calico printing, and painted and lacquered wood from the Futtehpore district. The exhibits came as a novelty to most who saw them. The calico printing is best seen in the ceiling cloths, which seem to be quite a speciality, as also in *jajims*, or floor-cloths, of a bold pattern and very effective. In lacquered and painted wood, the most attractive productions are the packs of cards, each 96 in number, and each differently painted, minutely and delicately.

.

POTTERY manufacture has made great strides at Lucknow of late years, and a very large variety was shown at Calcutta of glazed and unglazed, painted and plain, coloured ware. It is the same class of men who produce the terra-cotta groups of figures illustrating trades and handicrafts, and single figures representing types which fairly rivalled, and, in the opinion of many, exceeded, in artistic excellence a collection of terra-cotta figures of similar size which were exhibited from France. The manufacture of glazed tiles seems to be increasing and improving, some very good specimens being sent from Lucknow, and also from Futtehpore and Bulandshahr. The engraved, repoussé, and pierced brass and copper work of Lucknow has a character of its own, very different to that of Benares. At the latter city all is apparently worked for Hindoo taste, while at Lucknow the needs and tastes of a Mussulman community have also to be studied, leading to a distinct and different set of shapes and patterns. Bidri work has received accessions in the substitution of gold for silver as mounting to the black ground-work of metal, and when the gold is countersunk and not too thickly laid on, the contrast is perhaps more pleasing than in the case of silver. In some samples again the black metal forming the ground-work has by some treatment been coloured an olive green with an effect not displeasing. This occasional substitution of olive green for black as a groundwork may also now be found in Moradabad metal work, where it is perhaps still more successful than in bidri-ware. A point brought out at Calcutta is the existence in many districts of skilful wood-carvers and of artists in cabinet work, mustering perhaps but one or two in some districts, whose talent has been developed under discriminating patronage. Instances of this were found in exhibits from Aligarh, Gorakhpore, Ghazipore, &c. In particular may be mentioned a beautiful *étagère*, the joint production of two local artists of Ghazipore. Saharunpore again has been hitherto better known for its carving in white soft wood than for any other work; whereas, as proved at Calcutta, carving in hard wood flourishes there in a manner scarcely heretofore suspected.

.

DEWAR POTTERY is a glazed ware in quiet tints and patterns, and absurdly cheap. It is produced in a small town in the Bara Banki district. As in other instances well known, the potter refuses to communicate his secret even to other members of his family; and although he might by application drive a thriving trade, he continues to give a greater attention to a patch of land, and to look on an order for his wares more as a trouble than as good fortune. Bara Banki has another small industry carried on at the town of Zaidpore, in the shape of mechanical toys, showing great ingenuity, though roughly made.

In the town of Bulrampore and Utraula, in the Gonda district, Oudh, a few men carry on a trade in painting *petras*, or the baskets which with the native traveller so largely take the place of a travelling-trunk, and which also find a considerable place in a native household. The designs are brightly coloured, representing birds, flowers, &c.; jars, vases, &c., are also painted at Utraula in flower patterns, with very pleasing and artistic effect. A very large trade in perfumes is carried on in many towns, the principal of which are Ghazipore, Jaunpore, Lucknow, and Kanauj. The weaving and embroidery of muslin, though on a much lower scale than when there were native courts at Lucknow and Delhi to patronise it, is still a considerable industry. In the North-Western Provinces the chief seat of the industry appears to be Sikandarabad, in the Bulandshahr district, and again at Benares; while in Oudh it flourishes in Lucknow, and still lives at the town of Tanda, in the Fyzabad district, and at the town of Jais, in the Rae Bareilly district.

.

THE following is a summary of the report of the crops for the past year with special reference to wheat and cotton issued by the American Department of Agriculture:—The year 1884 has been one of average fruitfulness. In freedom from adverse meteorological influences of winter and early spring, so injurious to winter crops, it may be placed among the best in its results upon grains and forage grasses. Final reports of condition of wheat since 1870 have not averaged higher except in 1877 and 1882, though it was the same in 1874, and less by only one point in 1879, when the census average was thirteen bushels per acre. The season was less favorable for corn, though the best since 1870. The average of condition in October was 93, the highest of five successive years, following a series of five years all above an average, or of the last ten-fifteen years, very nearly twenty-six bushels per acre. The temperature of the season has made a somewhat eccentric record. In April the average of temperature of the whole country was lower than usual, except in the Pacific coast region and on the Northern plateau. In May it was slightly higher on the Atlantic coast, and a trifle lower than usual in the interior basin from Lakes to Gulf. It was still below an average in June in the Middle and Southern States, and up to or above the average in New England and the Central West. The average was not attained in July on the Atlantic coast, or by three or four degrees in the West, but was slightly exceeded in the Gulf States. August made some improvement in the great corn-growing section, while remaining somewhat below an average, the cotton States coming up nearly to an average, with such absence of rainfall or irregularity in its distribution as to seriously affect the condition of corn and cotton, and all late maturing crops. September made happy amends, with a temperature somewhat extraordinary over all crop areas except those of the Pacific coast. It was over twelve degrees above the average in the Eastern Gulf States, proving anything but a boon to that region. It was three or four degrees above an average in the West, and six degrees in the Middle States. In the more northern latitudes it proved an immense advantage in ripening the corn, saving it from another year's yield below an average. The unequal distribution of rainfall was a serious disadvantage in many districts. Drought was much more serious in the Ohio Valley than in the Missouri region, and Kansas and Nebraska have gained new laurels for abundance and reliability in crop production. As has been hinted above, there was a deficiency of heat for early maturity of maize in the belt of principal production, and for the development of other summer crops, and in some districts an excess of moisture in the planting season.

.

THE area of the previous wheat crop was greatly reduced by winter-killing and substitution of other crops. The present breadth is therefore greater by nearly 3,000,000 acres. The area harvested is estimated at 39,475,885 acres, which exceeds that in wheat in any previous year, in this country, as well as any other in the world. The report in April showed that in Michigan, New York, and Connecticut wheat was still protected by a covering of snow. Little mention of killing by winter alternations of temperature was made by correspondents. The fine appearance of drilled grain was generally attested. The

early-sown areas were superior to late sown in the Middle States. Seeding in Maryland was generally late, and only the early sown had a good growth and sufficient root development. The average date of sowing in Virginia was a few days later than usual, yet a fair growth was made in the autumn, especially in the grain districts of the Shenandoah Valley and among the best farms of other sections. A fair start, producing plants of medium vigor and promise, was made in the Carolinas and Georgia, and similar conditions produced average growth in Alabama and Mississippi. In Tennessee a vigorous root growth was obtained in autumn, and tillering commenced before winter set in, in the earliest and most advanced fields. The late seeding was not so successful. The soil was too dry at seeding time, at many points in Texas. In some cases the late sowings had the most favorable conditions, avoiding the drought that sapped the vitality of some early growths, causing either their entire destruction or great injury. The fields first seeded in West Virginia were the most promising. The later breadths were slow in starting, from drought and insufficient soil preparation, and not well fortified against the vicissitudes of winter. There was much mention of dry weather and slow growth in Kentucky, yet the development was very satisfactory on the best wheat soils. Drought had an adverse influence in the drier soils of Ohio, retarding development, so that the plants were generally small, yet with an appearance of health. There was great diversity of appearance on different soils. The lands improved by systematic drainage were uniformly promising of good results. The autumn was dry in Michigan, and the plants small when winter set in. The Indiana reports were not generally favorable as to early sown wheat. The medium seeding more frequently gave better results. The weather was too dry for an early start. Similar conditions prevailed in Illinois. Much of the crop had made but little growth when winter set in, and winter-killing of late wheat was feared. The seeding was unusually late. In Missouri the early growth was delayed by drought, but the later conditions were more favorable, and a fair growth was reported.

.

THE early sown is not always the most vigorous. Conditions were quite favorable for vigorous growth in Kansas. Rains were ample, and the ground was prepared better than in former years. On the Pacific coast the seeding was delayed by dry weather, but an increased area and fine growth was ultimately secured by reasonable and abundant rains. In May, condition was still reported high. In the more northern of the Atlantic coast States rain in excess, with low temperature, retarded growth, so that the plant was small, though healthy. In cold and wet soils of Pennsylvania and New Jersey growth was slow, while the mellow soils showed a stand rich in promise. The reports from Maryland indicated high condition, except on cold clay soils. The crop was already heading in North Carolina, and promising ripeness for harvest by the 10th of May. Prospects were generally favorable throughout the South, especially in Texas and Tennessee. Kentucky fields were in superior condition. North of the Ohio, condition was less favorable. In Ohio, Indiana, and Michigan condition stood fifteen per cent below the standard. There had been some winter injury in Illinois, and low lands had been flooded in the spring. The May reports from the Pacific coast were very favorable. It began to be observed in Virginia, Kentucky, and Indiana, and to some extent elsewhere. The early sown, as a rule, was most promising, and the drilled areas were decidedly superior to those sown broadcast. In this month the harvest was completed in the northern belt of the Southern States. The condition of spring wheat in June was very high, averaging 101. Winter wheat at the same time was reported at 93. The cool, moist weather had been generally favorable to healthy growth and to tillering. In July the condition of spring wheat was returned at 100, and of winter wheat at 94.

.

THE average farm price of wheat is 85 cents per bushel, against 91 cents last December. The December price in thirteen years has previously been below \$1 per bushel but five times—in 1874, 1878, 1880, 1882, and 1883. The average in Nebraska is 42 cents, 45 in Kansas, 46 in Dakota, 50 in

Minnesota, 55 in Iowa, 62 in Missouri, 63 in Illinois, 67 in Indiana, 74 in Michigan, and 75 in Ohio. The average home-grown wheat in New England exceeds \$1. In New York it is 85 cents, in Pennsylvania 86. It is 80 cents in Virginia, and 83 in Maryland. The price of wheat is lower than it has ever been reported by this department. It is said to be lower in Great Britain than any other period of the present century. It is a result that is perfectly natural, and that has been predicted repeatedly in these reports. A series of crop failures altogether unprecedented in Europe, stimulating production all over the world, could have no other outcome. These low prices, however, will soon reduce the area and relieve over-production.

**

THE area sown in winter wheat has been somewhat reduced in nearly every State reported. The prevalence of drought interfered with fall sowing of wheat upon the Atlantic coast. Lands intended for wheat could not be broken at the usual time on dry soils. The low prices had less influence in this region than in the West. In Alabama the partial destruction of last year's crop by frost was an additional cause of discouragement. Seeding was still in progress in some of the Southern States on the 1st of December, and it is probable that a portion of the deficiency has since been made up. The reduction of area amounts to about 8 per cent in the winter-wheat States, or over 2,000,000 acres.

**

THE plantation price of cotton, as reported, ranges from 9 to 9½ cents per pound. It is 9 cents in Tennessee, Arkansas, and Texas, 9½ cents in Louisiana, 9½ cents in Georgia, 9½ cents in the Carolinas and Virginia. The occurrence of two crops in succession, scarcely equal to the requirements of manufacture, has caused a slight increase in prices, and may produce a greater advance hereafter.

**

THE following is the telegraphic synopsis of the December report:—The December report of the Department of Agriculture indicates a smaller yield than the returns of condition in October. The October average was 74, against 68 in 1883, 88 in the great harvest of 1882, and 66 in the disastrous season of 1881. The returns of condition in October and of product in December have been unusually divergent this year. The first indicated a larger crop than last year; the latter a product slightly less, or about 98 per cent. The comparative decline is in the States west of Alabama. The comparison with last year is as follows:—North Carolina, 100; South Carolina, 107; Georgia, 101; Florida, 103; Alabama, 105; Mississippi, 94; Louisiana, 98; Texas, 89; Arkansas, 99; Tennessee, 101. Applying these percentages to our figures for the crop of 1883, they indicate a product of 398,000 bales in North Carolina, 502,000 in South Carolina, 760,000 in Georgia, 60,000 in Florida, 661,000 in Alabama, 847,000 in Mississippi, 480,000 in Louisiana, 995,000 in Texas, 513,000 in Arkansas, and 314,000 in Tennessee. The remaining territory will probably give about 50,000 bales. This makes an aggregate of 5,580,000 bales. These figures are provisional, and may be slightly by future returns. It is possible that the general pointment at the outcome of the middle and top crop have made the December returns unusually conservative, but it is certain that the rate of yield will be much below the average. It is the experience of the department that returns of final product are much too low, not by a uniform percentage, for the local estimates are more depressed in a year of partial failure, than in one of good yield. The inevitable tendency of declining production is to depress the spirits and blast the judgment of the reporter. The peculiar features of the present crop history cause a wide discrepancy between condition in September and October, and comparative product reported later. In allowing this depression, in such a year as this, there is a possibility that figures may remain too low. The October returns of condition, notwithstanding the difference in subsequent dates of frost, have in former years pointed quite closely to the result. In the census year the October average was 74 and the crop 5,755,359 bales.

THE average of condition in October, and the commercial movement for four crops since 1879, bear relation as follows:—

Years.	Average.	Movements.
1880	...	84 8,005,760
1881	...	66 5,456,048
1882	...	88 6,910,758
1883	...	68 5,713,200

The October average of 1884 was 74, but the failure of subsequent fruitage was very marked, making it evident that these October indications would not this year point so nearly to the ultimate product. It would still seem possible, however, that the crop may equal that of last year, though the December returns do not warrant such a conclusion, and they are given above, with such corrections only as former experience has shown to be necessary. While it is absurd to report local estimates, or census returns even, without revision and correction, it has been the practice of this Bureau to give from month to month a fair interpretation of the returns, and not an individual estimate based on them. The interested public can thus read the history of the crop development and disasters, and reach a conclusion in accord with it; and it is very certain that individual conclusions will ever be modified by personal interest, whatever the official figures. The quality of cotton is unusually good. There was little damage from rain, and a small proportion of stained fibre. Some correspondents declared that there was no cotton. Similar reports came from Georgia and Alabama, and substantially from those further west. The falling off of the top crop—the blighting of the later bolls, and their failure to mature—is almost unprecedented, according to the returns of correspondents.

**

FROM a report on the railway-borne traffic of the North-Western Provinces and Oudh during the official year 1883-84, we find that agricultural products formed 73 per cent of the total exports from these provinces. It is, therefore, evident that the character of the traffic must greatly depend on the agricultural conditions of the country, a short notice of which is indispensable for an explanation of the changes in the traffic of the year under report, when compared with that of the previous years. The seasons which principally affected the transactions in different staples (except cotton and sugar) were the *rabi* and *khari*, reaped respectively about March and October, 1883. Cotton and sugar came into the market much later than other *khari* crops, and the crop gathered in any year continues to be exported in pretty large quantities during the first quarter of the following year. Their traffic was therefore affected partly by the crop of 1882, and partly by that of 1883. The *khari* rains of 1883 had terminated early, and by the time the *rabi* sowings came round, the moisture left in the ground was barely sufficient for the proper germination of the seed. The prospects were gloomy except where canal irrigation was available; and had it not been for the rains of January, the total outturn of the provinces would have been unusually small. The rain which fell on the 9th and 10th of January 1883, proved very beneficial, and the heavy falls on the 25th and 26th of the same month entirely changed the prospects. The high winds which accompanied them did some damage to the crops which, sustained by canal irrigation, were in many places most forward. Rape and mustard suffered to some extent from blight generated by the cloudy weather of March, and linseed from frost; but the season was on the whole a very fair one. Representing the full crop by 100, the outturn of wheat and barley was from many districts returned at 100; and if the average of the whole province be taken, the outturn of wheat, barley, and *rabi* pulses may be indicated by 87, 87, and 81 respectively. The *khari* was characterised by scanty rainfall which considerably damaged the rice and sugarcane crops; the outturn of millets and pulses was from most districts returned at less than three-quarters of the normal outturn; cotton and teel, which do not feel so much the effects of a comparative drought, were the only crops which approached to a fair average.

**

OF the food-grains the prices of rice alone during 1883-84 show a rise over those of 1882-83, owing to the crop having been a very short one in these provinces and in Bengal. The

price of wheat did not rise in the face of a very large export during the year. This was due to the excellent crop of 1883. The prices of linseed and rapeseed were higher owing to the injury they had received from frost and blight. The price of ghee was higher, due to the early cessation of the autumn rains which had reduced the supply of fodder in the tracts bordering on the Jumna, where most of the ghee is produced. The prices of cotton and sugar were affected more by the crops of 1882 which amply fed the market during the first three-quarters of the year.

THE exports and imports both exhibit a considerable increase over those of the previous three years. Compared with the figures of the preceding year, the exports show an increase of 58 lakhs of maunds and 56 lakhs of rupees, which is mostly due to larger exports in cotton, wheat, other grains, coal, and railway materials. Imports exhibit an increase of over 17 lakhs of maunds and 122 lakhs of rupees, due chiefly to larger imports in cotton goods, iron, coal, and railway materials.

NOTWITHSTANDING the opening of the Rajpootana-Malwa Railway which has brought Bombay into much closer connection with the western half of these provinces, Calcutta easily maintains its lead. Judging by the value, it received considerably more than half the total exports sent out from the North-Western Provinces and Oudh during the year under report, and supplied over 45 per cent of the total imports received by the united Provinces. Bombay received 9 per cent of the total exports and supplied about 12 per cent of the total imports. The traffic with the neighbouring provinces amounted to nearly 40 per cent of the total traffic during the year.

IN the trade of Cawnpore the imports of wheat and oilseeds from places inside the provinces show a steady decline. This is probably owing to the produce of Oudh, which formerly used to find an outlet at Cawnpore, being diverted to Benares. The exports of wheat to the ports have accordingly declined in the face of the very considerable general increase from all parts of the united Provinces. That the exports of oilseeds have not shown a decrease is simply due to larger supplies from Bundelkhand by rowl. Cawnpore would appear to be losing its ground as a collecting centre for the produce of Oudh; but even in its present stage its total traffic amounts to nearly one-fourth of the total traffic of the united Provinces, and is almost equal to the traffic of Agra and Delhi taken together, if we exclude the quantity of coal and railway materials which Agra received from Bengal for transmission to the Rajpootana line, and which should, properly speaking, be credited to Rajpootana.

IN cotton the exports of 1884 exceeded those of 1883 by nearly 2½ lakhs of maunds. The whole of this increase was due to the crop produced in 1883, which arrived in the market in the third quarter of the year under report.

	1883-84.	1882-83.
	Mds.	Mds.
Exports in the first two quarters	2,65,719	2,54,642
Ditto last ditto	13,69,980	11,42,852

MORE than 56 per cent of the total exports were taken by Calcutta, about 30 per cent by Bombay, and a little over 8 per cent by Bengal. The Punjab and Southern India also took comparatively large quantities during the year; most of the cotton sent to Southern India was taken by Ahmedabad for consumption in its mills. The exports were almost entirely from the Meerut, Agra, and Allahabad blocks, which are the largest cotton-producing divisions of the North-Western Provinces.

THE sweetening power of sugar made from cane, as compared with that made from beet-root, is a question upon which different opinions exist. Some say that it takes 1½ lbs. of beet sugar to produce that sweetness obtained from 1 lb. of pure cane sugar. Others, that it takes 1½ lbs. of beet to equal 1 lb. of cane. Whichever it is, the difference is an important one, and one which our West India Committee would do well to have put to a practical test—say, by inducing one of the large institutions, such as Eton, Harrow, or Rugby, where sugar is

used *ad libitum*, to use cane sugar for three months and then three months of beet. If the result in the consumption supported the opinions above mentioned, to have it published in all our papers, and a copy sent to every grocer throughout the three kingdoms. If this could be done, and the difference between cane and beet sugar, here stated, be clearly demonstrated, it would do more to bring about a healthy public opinion in favour of our own cane-grown sugars, than all the deputations to Lord Granville, Lord Derby, and all the Anti-Bounty public meetings put together.

THE following is a summary of Messrs. William, James, and Henry Thomson's fortnightly circular:—Upwards of 46,000 packages of tea have been brought to market during the past fortnight, 900 of these being Ceylon tea, and 1,500 packages second-hand and reprinted parcels. A less active business in the country, and the large supplies at the moment available, have checked anything like speculative buying; but upon the whole the dealers have been encouraged to operate by the heavy deliveries, and the rapidity with which the crop is being disposed of, and there has been sufficient competition to cause prices slowly and gradually to harden for all but the commonest kinds of tea. Demand as before has been strongest for fine qualities, but latterly more attention has been paid to grades between 9d. to 1s., and to showy Pekoes and Broken Pekoes, between 1s. and 1s. 3d., which now appear relatively cheap; and prices for these have improved a little. The superior quality of the later manufacture, already referred to, becomes more clearly marked as the season progresses, and supplies now coming to market afford a better selection than for some time past. The deliveries of Indian and Ceylon, during January, were 6,489,000 lbs. as compared with 5,605,000 lbs. last year; the total delivery for the month being 1 million lb. heavier. The question whether the current season's supplies will suffice to meet our requirements, at the rate of consumption now reached, is attracting some attention. On page 3 will be found figures showing the position, based upon the actual shipments to 31st January (56½ million lb.). The result shows the visible supply to be 1½ million lb. less than last year; assuming, therefore, that the increase in consumption is maintained, stocks will be reduced to a lower point than usual—perhaps to less than two months' consumption—before the autumn supplies are received. It will be remembered that last season London weights were more than 2 million lb. above Calcutta; this season, however, so far, we find no appreciable difference. The *Justitia* (s) lost, carried 500,000 lbs.

ON the 6th ultimo, Captain B. D. Plummer, referring to the Mysore Gold Mining Company, reported:—Mining Operations.—Last month the following work was done underground at this mine:—Taylor's shaft, sinking below the 173, was sunk 5 ft. 9 in., the lode has a greater underlie than the shaft. The part we carried was composed of hard dolerite, with strings of quartz, worth about 1 oz. of gold per ton. We are now in hand putting in timber, and, to do this properly we have to cut down some part of the lode. I shall be able to give an idea what it is like next week. The north end at the bottom of Taylor's shaft was driven 3 ft. 10 in. The lode is 4 ft. wide; all the work was somewhat impeded by defection of the underground coolies in the early part of the month. The south end, at the bottom of Taylor's shaft, driven 2 ft. 3 in.; but the greater part of the month has been taken up in cutting into the west side (where the lode shifted to). There is a fine lode 4 ft. wide. The lode in bottom of the mine continues to look promising, and, tho the speed appears to be slow, we are doing our utmost. I am unable to suggest any improvement, except we get European miners. We commenced work below the March last, and, in addition to sinking the shaft 69, we have put in pit-work, cleaned out the old workings, secured them. Though it is slow, yet when we consider the nature of the rock, and the men we work with, it is satisfactory. The north end lode has been driven 13 ft. 4 in. The lode there is a good wall, but I am now unable to report any improvement, though I think it sufficiently important.

with the driving. No. 1 rise in the back of this level has been put up 14 ft. 6 in.; the lode is 4 ft. wide. No. 2 rise has been put up 30 ft. 5 in.; the lode is 1½ ft. wide. The 135 north end on each lode was driven in the month 42 ft. 10 in. There is no lode at present, but the old workings are wide, and extend from bottom to top of the level. The cross-cut south of the shafts from east to west lode in the 173 has been completed. We have started a winze, and it has been sunk 6 ft.; the lode is 12 in. wide, of good-looking quartz. I have set an end to be driven south of the cross-cut on the west lode. After it has been driven 10 or 12 fms., I intend to open on the lode, and sink a winze, if the water will permit.

.

A RESOLUTION of the British Burmah Government on the Report on Settlement Operations in the Tharrawaddy and Prome districts, season 1881, contains some highly interesting notes on the condition and prospects of the people inhabiting them. The rainfall and soil of different parts of this tract are diverse. In the south the mean annual rainfall is 98 inches about Sanywe; in the north at Prome, between the towns of Mahathamman and Shwedaung, the mean annual rainfall is 53 inches. In the south we have the rich deep soil of the delta; in the north the soil is lighter and shallower, and the country is cut up by laterite hills and ridges. In the north of the tract villages are larger, population is denser, cultivable waste is rarer, and holdings are smaller than in the south. Very little of the cultivated land is subject to inundation, but in the northern circles the rice often suffers from drought, though anything like complete failure of the rice crop has not been known within living memory, even in the drier parts of the Prome district. The distinctive characteristics of the north and south parts of the settlement tract shade off, and disappear near the Kantha stream and Paungde, which are about the middle of the tract. The average area of a cultivator's holding ranges from 4·2 acres in the south to 1·3 acres in the north. In the circles of Prome cultivators mostly earn a part of their living by plying with their carts, by catch-boiling, by fishing, by sugar-boiling, or by silk-growing. Though their holdings are small and their soil is less fertile, yet the cultivators in the northern circles are apparently as well off as in the southern circles. Throughout the whole tract, cases of "hopeless indebtedness" are said to be few. Substantial pagodas, monasteries, rest-houses, and other works of merit,—such as Burmans usually construct out of their savings,—are "very plentiful" in the Prome district. The landless classes, who constitute about one-fifth of the population, are in a less prosperous condition than the cultivators. Where holdings are small, sub-tenants are naturally few, and are found chiefly on fields owned by widows, or minors, or other persons unable to work. Altogether 7,527 acres, or 3·5 per cent of the cultivated land, were held by tenants, who pay on the average about Rs. 3-4-0 per acre for land revenue and rent. This payment is nearly treble the present land revenue rate. The selling price of land ranges from Rs. 16 to Rs. 33 per acre, being highest in the northern tracts, where the area of waste available for rice cultivation is smallest. These rates are higher than have been found in the more fertile tracts of the delta, where the area of cultivable waste is still considerable. The density of the population ranges from 316 to 394 per square mile in the several townships; this rate is computed in the open country, excluding of hill and forest. The majority of the agriculturists. Means of communication by road, and river are good, and the tract sends its surplus rice southwards to Rangoon and northwards towards Mandalay.

.

THE last revision of the settlement rates took place in 1867, the rates as then settled ranged from Rs. 1-8-0 to 8 annas. During the past 16 years the cultivated area has increased from 122,413 to 166,871 acres, and the total revenue paid on the cultivated land has risen from Rs. 1,46,326 to Rs. 4,542. The average incidence of the land revenue demand of 1883 was Rs. 1·43 per cultivated acre according to the measurements, and Rs. 1·15 per acre according to the rates fixed by the cadastral survey. The revenue has never been collected with very little coercion of force, but is paid to the people. The cadastral survey showed

the cultivated area to be 207,368 acres as compared with 166,871, according to the latest measurements by thugya. The discrepancy between the survey and the thugya areas ranged from 44 per cent in comparatively new lands of Tharrawaddy to 20 per cent in older villages of Prome. The result of cutting the rice crops on 142 patches of land in the Tharrawaddy and Paungde townships gave an average yield of—

42 baskets per acre on	...	I class soils.
30 baskets per acre on	...	II class soils.
19 baskets per acre on	...	III class soils.

These rates are somewhat below the average yields ascertained in the southern townships of Tharrawaddy. No crop-cutting was done in the Shwedaung and Mahathamman township. The average prices obtained by the Prome cultivators for their paddy during the past five years have been higher than the Tharrawaddy prices by reason of demands for the Mandalay market. Owing to the greater density of population and to the scarcity of cultivable waste, wages are lower and the cost of cultivation is smaller per acre than in tracts nearer the delta. Though the cultivator has been getting higher prices for his paddy during the last few years, he has not—so the Settlement Officer reports—to pay any more for the salt, tobacco, fish, and other necessities which he consumes.

.

THE Settlement Officer's proposed rates, when applied to the land, yield an increase of Rs. 53,700, or 29 per cent on the rice lands, and of Rs. 2,349, or 16 per cent on the garden lands. In some large kwins (village areas) the proposed new demand is more than double the present revenue. The incidence of the present and the proposed assessments on the new or cadastral survey areas is as follows:—

	Rs.
Old or present assessment, with cess ...	1·15 per acre of cultivated land.
New or proposed assessment, with cess ...	1·85 per acre of cultivated land.

These rates are low compared with the prevailing rates in the delta districts. But it has to be remembered that the cultivator has to pay out of the profits of his farm, or out of his other earning, not only the land revenue but also the capitation tax. The latter impost, at Rs. 5 per family, falls lightly on an average holding of 36 acres in the delta districts; but it falls very differently on an average holding of 1·6 acres in Shwedaung, or 1·3 acres in Mahathamman. The owners of these small holdings cannot live wholly, perhaps many of them do not live mainly, by their land. Probably the proposed assessments could and would be paid. But the smallness of the holdings, and the consequent inability of the cultivators to live by the proceeds of their lands, must be factors in deciding whether or no large increase can properly be made in the land revenue demand.

PERUVIAN GUANO.

WE had occasion the other day to refer to the Peruvian guano, and to remark on its utility as a manure. The subject has attracted some degree of attention at home, and we are glad to find that the matter has been taken up by a competent man, like Mr. Church, for many years Professor of Chemistry at the Royal Agricultural College, Cirencester. In raw Peruvian guano, as we said, although it consists chiefly of the excrement and urine of marine birds, there is a very fair mixture of the altered remains of their dead bodies, and of the bodies of other animals. There has been a chemical change in these matters, and they form a nearly uniform mixture, which loses little of its value in those parts of South America which are comparatively rainless. Now the worth of guano as a manure may be accepted as a fact, when we come to know that many preparations offered to farmers are called by that name, to which they have no right. Owing to adulteration, these things possess little or no power to increase the yield of the land, while those which are capable of improving the crop are generally defective. It is for this reason alone, that no artificial or mixed manures, yet invented, have been able to take the place of raw Peruvian guano. It will best be apparent when we consider what is needed in a manure, and what are the distinctive features of the guano, in comparison with its substitutes and imitations. In the first place, manure is used because agriculture makes much more severe demands upon the soil than nature. In

agriculture, instead of restoring what is drawn from the soil, or what the plant takes in from the atmosphere, the farmer removes from the land altogether, in the crops, and cattle, and dairy produce which he sells, large quantities of the most valuable substances, such as nitrogen, phosphorus and potassium. But this is not all, nor is it the only reason why agriculture must restore by art the losses of the soil. The farmer extorts from the land more than it can yield in the natural course of events; he insists upon thirty bushels of wheat where nature would give but fifteen. There is so much extra productive power required in the land that this demand must be met by giving more food to the plant, and food of the right sort. Besides this, the farmer is more exacting, and instead of allowing wild plants and weeds to grow, he dictates to the soil what kinds of plant it must support for his profit. And he will persist in growing the same succession of plants every four or five years. Now, in order to succeed in procuring these artificial results, the agriculturist must feed his land not only in a liberal manner but with skill. Farm-yard manure is good, but cannot always be got, and when used too freely in large quantities, year after year, leaves in the ground an immense quantity of unused nourishment; it must therefore be supplemented by other manures, and this want is supplied by raw guano. Now the question which naturally suggests itself is, "Why cannot the farmer get what he wants in artificial manures and mixtures?" The three chief materials which he wants to feed his crops, are nitrogen, phosphorus, and potassium, and these may be bought most cheaply in nitrate of soda, coprolites, and kainite. Why then cannot these things be so mixed up with other materials necessary to make up their deficiencies as to become an artificial guano, for all purposes identical with that produced in Peru? We will let the Professor answer the question himself. He says:—"Surely such a mixture will *analyse as well as guano*—so much nitrogen, so much phosphorus, so much potassium—and it will cost less. "But the weakness of this argument lies in the fact, that such artificial manures do not really present those necessary elements of plant food in the same forms as those which are found in guano. Moreover, they do not contain so large a variety of such compounds, nor are they associated with the same substances—substances of little direct use, it may be, to plants, but serving important indirect purposes. And, we may add, the mechanical or physical state of these artificial manures usually differs much from that of guano.

Our next argument in favor of guano is offered with some reserve, not because we suspect its soundness, but because it may easily be pushed too far. We have no unreasoning prejudice in favour of natural manures as against artificial, but we must give due weight to the fact that, in the perpetual circulation of matter which goes on in the world, the mineral kingdom sustains the vegetable, and the vegetable the animal. And we know, too, that animals during their life and after their death yield various matters, which, both in their chemical composition and their mechanical state, are particularly well fitted, as they gradually return to what may be called a mineral condition, to nourish plants. Briefly, the earth feeds the plant, the plant feeds the animal, the animal feeds the soil. Compared with the immense quantity of matter in the crust of the earth, this matter in circulation between the three kingdoms of nature, is a mere trifle, but then it is going its regular round, and doing its proper work, for which it is perfectly adapted in every way. Further, some of this matter in circulation, including much valuable nitrogen and phosphorus, is every moment dropping out of circulation and is lost to agriculture, being carried into the rivers, and by the rivers to the sea. And so it is a fortunate circumstance that we are able by such a manure as guano, produced mainly by sea-birds which feed on sea-fish, to reclaim from the ocean a part of the lost treasures of the land.

And now we must hasten on to say something definite about the properties and composition of guano itself. Let it be granted that we are dealing with an average quality, yielding, on analysis, fair proportions of nitrogen (expressed as ammonia), of phosphorus (expressed in the form of pure bone earth), of potash, and of so-called "organic matter." But the figures of an analysis do not suffice to explain the whole story of the efficacy

of this manure. How is it that for centuries guano alone has maintained the otherwise barren sands of these South American shores in a state of admirable fertility? We attribute this result, and similar results in other countries, not merely to the richness of this manure in plant food, but also to its very complex composition and its remarkable mechanical state. The soft light powder is not so fine as to be washed away through the soil, nor so coarse as to remain without becoming commingled with the earth. Its power of taking up and holding water allows those chemical changes to take place in it, without which its full power of nourishing the crop could not be developed. It is ever giving out carbonic acid gas, which makes the bone-earth of the manure dissolve, and so brings it into the state in which it can enter the roots. And, above all, its nitrogen and phosphorus exist in several forms, some at once ready for the use of plants, some soon becoming available, and the others being brought into activity later on. Thus, an average sample of guano just analysed contained nitrogen in at least six different forms—namely, nitrates, nitrites, ammonia salts, uric acid, guanine, and a substance more complex than any of these. These several things become ready for the use of the growing crop in the order we have named, at each stage of the plant's growth something being prepared for it. This important property of raw guano may be illustrated by many familiar examples. Take one—the case of a sprouting wheat-grain. The embryo, germ, or chit, is there associated with an abundance of manurial elements—nitrogen, phosphorus, and potassium. Compounds containing these elements are crowded within and around the parts where growth begins, to an extent three times as great as that in which they exist in the other parts of the grain. But they are not all at once ready for use, nor does each occur in but one form or condition. Step by step, as the substance of the sprouting grain decays, these nutritive matters become free and suffer change, yielding a variety of compounds each serving some useful purpose. Much in the same way, the plant finds in guano materials which can be turned to account exactly when they are needed. For this reason attempts to use nitrate of soda, or sulphate of ammonia, in place of the nitrogen compounds of raw guano, do not fully succeed in actual farming practice. The influence of the manure is at once too intense and too fugitive. While it acts, it acts too strongly, and afterwards, when we want its help we find that it has all been washed away. Sulphate of ammonia, though retained in the soil longer than nitrate of soda, has the same defects. As with the nitrogen, so with the phosphorus; there are present in raw guano phosphates of ammonia, of potash, of magnesia, and of lime, which, like the above-named nitrogen compounds, come into use one after another, feeding the crop step by step as it needs help, and yet being kept about the roots till required. It should be added here that so great is the solubility of the more valuable parts of raw guano that mere rain water will at least extract 80 parts out of every 100 parts of its nitrogen, and nearly 50 out of every 100 of its phosphorus, even the undissolved residues of these two things finally becoming themselves soluble, and therefore useful, as the guano changes in the soil. This should be borne in mind in connection with the use of strong chemicals, like oil of vitriol, to make guano more soluble. This treatment not only impairs its admirable mechanical texture, but breaks up the numerous and peculiar compounds upon which the progressive action of guano depends, reducing it in some measure to a common-place level of an ordinary artificial manure.

It would, however, be unreasonable to argue that there are no circumstances in which the addition of other substances to guano, or its chemical treatment, may be advisable. For fixing the ammonia of those guanos which are so rich in that ingredient, or are so constituted as to lose an appreciable amount of it, by ordinary exposure during transit or unavoidable storage, the process of "dissolving," or "sulphating," possesses unmistakable value. When, too, we have to deal with hard and intractable guanos of the phosphatic class, their conversion into a peculiarly effective form of superphosphate is clearly desirable. The treatment of guano with sulphuric acid was patented by Dr. Richardson, of Newcastle, so long ago as 1859. It has done good service, but it always involves a large addition of non-manurial matter—about 1 ton of acid to

5 tons of guano is usually employed. Not infrequently the addition does not stop here, for sawdust, peat, and other useless substances too often follow in the wake of the oil of vitriol. Now-a-days the introduction of sulphate of ammonia is required in order to bring up the treated guano to the guaranteed strength. When raw guanos contained nitrogen equal, not to 8 or 9 per cent of ammonia as at present, but to 13, and occasionally even much higher proportions, then some method for preventing the escape of that constituent was often needed. An instance of this was furnished by a Peruvian guano imported in 1865, which lost by mere keeping for a few months in a corked bottle 9½ per cent of ammonia, the total originally present having been nearly 21.

COORG.

In the last administration report of Coorg, we find that the extent of land under food-grains remained stationary. Seventy-three thousand and twenty-one acres have been cultivated with rice, and 1,433 acres with dry crop, or 6 acres less than in the previous year. The most important, although not now the most paying, industry in the province is that of coffee-planting. There are 218 coffee estates owned by Europeans and 44,428 by natives, covering a total area of 74,074 acres. The area of the land held by the former is 38,213 acres on an assessment of Rs. 69,398, and by the latter 35,861 acres on an assessment of Rs. 65,892. Besides these, coffee to a large extent is grown on the *bund* (uplands attached to rice fields), the extent of which is roughly calculated at 13,000 acres. The average size of each coffee plantation held by Europeans is 185 acres and by natives 8 acres. The number of persons resident on European coffee estates and large native estates is 26,893, according to the last census, taken on the 17th February 1881, but this number is augmented by about 20,000 during the pick ag season which closes in January. Of the whole area of land under coffee cultivation, 41,600 acres are said to be in full bearing. Owing to the heavy crop picked the outturns, estimated at 2 cwt. the acre on native, and 4 cwt. on European estates, come to about 5,109 tons, being almost the double of the previous year. Calculating the average cost of cultivation at Rs. 100 per acre on European estates and Rs. 40 on native, each cwt. of coffee cost on an average Rs. 23 to produce. The cost of cultivation, at the rates per acre assumed above, comes to nearly twenty-nine lakhs of rupees. Of this not less than 60 per cent may be estimated as having been the price of labor. The value of coffee produced, taking the selling price to be on the average Rs. 25 per cwt. on the spot, comes to Rs. 25,54,000.

An agricultural farm has not yet been established in Coorg, but efforts were made during the year to improve products by the introduction of fresh seed. A fine quality of rice, which was obtained from Alur, has been cultivated by the ryots successfully, and another variety known as the jira, has been obtained from Canara, and will be tried this year.

Unfortunately most of the wheat received from Cawnpore failed to germinate; while that obtained from the adjoining Hassan in Mysore, though it gave every promise of

in the Nanjarajpatna Taluk, was damaged completely two very heavy and altogether unexpected downpours of rain in the month of December, which ruined at the same time the ordinary Bengal-gram crop grown by the ryots.

The potatoes, carrots, Bellary onions, squashes, Mlseed, Japan, French and broad beans, supplied to the market gardeners, rotted away in most taluks from the same cause, and partly from want of care, but they succeeded fairly in others. Their cultivation was introduced from Hassan, where they were first raised several years ago from seed distributed by the present Commissioner of Coorg.

Tobacco seed from Dindigui and Coimbatore, of the variety from which Trichinopoly cheroots are made, succeeded in the Nanjarajpatna and Yelsavirshime taluks.

A good variety of ginger introduced from Shernad in Malabar is thriving well in most taluks. The introduction of the pepper vine from Malabar proved a failure from the cuttings having rotted in transit.

For the first time for several years past, the planters experienced great difficulty in procuring a sufficiency of labor for plantation work. The Mysore coolies were late in coming in, and, when the batches did arrive, they were less than half the number for whom advances had been made. The causes assigned were the abundance of the crops which had caused a fall in prices of food grains, and the demand for labour on the Bangalore-Tumkoor line of Railway which was under construction. Some of the estates suffered from the weeds not having been removed in time, while in other cases the managers and proprietors were saved from heavy loss only by the strenuous efforts which they made to import labour from the Tamil country near Salem, and by employing the costly but valuable labour from the Western Coast. Owing probably to questions affecting the tenur of land in Malabar, the numbers of coolies, chiefly Moplas, who were attracted from that part of the country, were unusually large; and with their aid the difficulty of securing the crop was aided over. Many of the Tamil coolies, who were imported, failed to give satisfaction, but others have done well, and their advent to the country is welcomed, the more so as many of them are willing to engage without advances. The Mopla labourers proved also most useful in doing good work on petty contract on the roads.

To compensate, as it were, for the losses in the previous years, the number of deaths among cattle was comparatively light, being 2,608 head against 14,347 in 1882-83; and this notwithstanding that the rain-fall was fully up to the average. Evidently, nearly all the weakly cattle had succumbed to the heavy monsoon of the year before.

No greater blow has been dealt for many years past to the prosperity of Coorg, and to the coffee interest, which it owes its flourishing condition, than the heavy fall in the market price, which took place at the close of the season. It has decreased from Rs. 40 to Rs. 25 the cwt. within the last two years, and in the Home market from 100 shillings to 61 shillings, or 40 per cent. The cause is attributable to the overstocked condition of the London market. The *Times* in a recent issue describes the stock as apparently exhausted, and states that it is not known to how low prices may still fall. Ceylon and Coorg have to compete with Brazil where there is slave labour, and where fresh land is said to be abundant. The extension of railway communications in Brazil is another advantage in favor of that country, and in recent years the planters there have been taught by settlers from Ceylon the proper manner of curing and preparing coffee, so that Brazil coffee has lately obtained in the home market as good a price as that of Coorg. The native coffee is chiefly in request for the French market, to which quantities have been exported direct from the Western Coast.

Owing to the good crops reaped in Mysore, the prices of food grains showed a tendency to fall still lower. Rice, the staple crop of Coorg, fell to Rs. 1-12-0 the maund of 80 lbs., or annas 12 less than in the previous year, and ragi to Rs. 1-2-0 or annas 5 less. The market was so dull at the end of the harvest in the Yelsavirshime taluk, that sales could not be effected for some time. The ryots acknowledged the liberality of Government in giving them time to effect a sale by the recent alteration in the payment of instalments of revenue.

The rain-fall during the year was slightly above the average:

	Inches.	Cents.
That registered in Mercara being ...	140	29
" in South Coorg ...	80	35
" in East Coorg ...	44	33
" on the Western Ghats ...	252	79

The season opened very favorably for all agricultural operations. The timely blossom showers led to fine crops of coffee and cardamoms being picked. The subsequent rains ensured the safety of the rice crop, which was fully up to the average, but in Eastern Coorg serious damage was done by the heavy rains to the ragi and Bengal gram crops, especially by two unexpected downpours, which took place in the month of December. These showers caused also some damage to the coffee crop when drying on the barbaques, and to the rice crop in South Coorg.

Miscellaneous Items

THE latest reports from the Assam tea districts are good, and should the weather continue favourable, a somewhat earlier season than that of last year may be anticipated.

RAJA UDAI PRATAP SINGH, of Bhinga, has made a grant of Rs 100 to Pandit Sri Lal, Secretary to the Bijnour Agricultural Society, towards his expenses at the Royal Agricultural College, Cirencester, whither he proceeds in April next.

On the suggestion of Mr. Havell, the Superintendent, the local Government have directed that wood-carving should be taught in the Madras School of Arts, and while Mr. Havell was on tour, he managed to secure the services of an experienced workman from Ramnad. The school is largely resorted to by pupils in Madras, and from the mofussil.

THE prospects of the shareholders in the More Gold Mining Company still continue to improve. The last report from J. D. B. Plummer, the manager, says that on the 19th of January, 48 tons of ore yielded 129 ounces of gold, and 129 tons of other quartz yielded 28 ounces, giving a total of 231 ounces of gold produced from 177 tons.

THE value of gold imported to this country, during the first ten months of the current financial year, was Rs. 4,50,26,335, whilst that of silver imported was Rs. 5,61,90,934. This leaves a balance of both metals in favour of imports of Rs. 10,12,17,299. The assay value of coins and bullion received at the Indian mints from the 1st of April last to the end of January, was Rs. 4,56,49,031, and of those coined and examined, Rs. 4,52,74,404.

THIS staple article of export from Pondicherry (ground-nuts) has commenced to arrive in small quantities, but owing to the uncertainty that prevails as to the out-turn the present quotations are purely nominal, and not to be depended on; last year the rate, during the shipping season, varied from Rs. 11 to Rs. 16 per French catty (560 lbs. English). The crop is lost almost entirely, within a distance of twenty to twenty-five miles from the coast.

A CORRESPONDENT writes:—"We had a shower of rain on the morning of the 1st, an event that deserves to be chronicled, at Ad, but it was so slight in the Settlement, that the only effect it had was to soften the ground for a cricket match at the 'stump' position. Heavens, never, ever, over the hills beyond Lake, which but a few days ago was a barren waste, a country from which we draw our rice and other supplies."

A WRITER in a Mauritius paper draws attention to the food-supply obtained by Mauritius from Madagascar as a fruitful cause of fever. He declares that the live-stock imported is in the worst possible condition for human food, and that other supplies prepared in Madagascar are so carelessly and filthily got ready for the Mauritius market as to be anything but a proper staple of food. He suggests a stricter examination in the case of prepared supplies, and a strict system of quarantine in the case of live-stock.

THE Chinese tea merchants at Foochow have issued a manifesto to the tea-growers up-country, warning them of the decadence of the tea trade with foreign countries, and calling their attention to the large increase of late years in the sale of India teas. The circular also insists on the necessity for more care being used in both the cultivation and preparation of the tea, if the trade is not to be entirely lost, and it points out that the prices have declined at least one-half since 1870, and that the losses to the trade have been very severe.

THE following ruling of the Board of Revenue, Madras, has been approved by the Government:—"Poppy-heads cannot be excluded from the operation of the Opium Act, as section 3 defines opium so as to include poppy-heads. It appears that an intoxicating drug is made out of poppy-heads in Northern India. In this Presidency, however, they are exclusively used for medicinal purposes, and the trade in them is very small. The Board recommend that the fee of Rs. 3 levied on licences to sell poppy-heads be reduced to eight annas."

A CORRESPONDENT writes:—"Dame Nature played a strange freak in my wife's poultry yard. Your correspondent alludes to small-sized eggs with no yoke. The one laid by our English fowl was of the usual size, but on the shell being broken and the contents poured into a dish, out came not only glair and yoke, but a small egg with a perfect shell which had evidently been floating inside the large egg. This small one, which was about the size of a pigeon's egg, had no yoke. With the exception of its size, in shape and appearance, it looked like any natural egg. Can Dr. Shortt explain this freak of nature?"

THE Murree Brewery Company have advertised a new issue of scrip, to the extent of 100 shares, of Rupees 100 each, to assist in paying for the Nilgiri Brewery Company's property which they recently purchased. The purchasers of the new shares, we learn, will be entitled to half-a-year's dividend; the last seven dividends having averaged 13 3/7ths per annum. The Murree Company have always done a profitable business, which seems likely to be augmented by the extensions now being undertaken in the Madras Presidency, and we think the prudent investor may safely take the offer advertised into consideration. The Company's Rs. 100 shares are at present quoted at Rs. 140.

ANENT Silage, Mr. Jas. Howard, of Bedford, M. P., writes:—"The result of my experiments may be summarised as follows:—1. That the production of silage of uniformly good quality, with a minimum of waste, is possible. 2. That the cost and trouble of top-weighting, of any kind, is unnecessary. 3. That the uncompressed portion of fodder at the top of the silo is equal in quality and flavour to that in the middle, or at the bottom and sides. 4. That the silo may be filled up at different times during the season without damage to the first material put in. 5. That under ordinary conditions no attention is requisite during the process in regulating the range of temperature."

It seems probable that the despatch of coolie emigrants from Calcutta to Mauritius will soon be put a stop to. At least such is the opinion of the St. Louis Commercial Gazette. Already, it appears, the Mauritius Government have had to put up with the loss of Rs. 20 per head, and food, for a month, for 111 coolies lately landed, and there are time-expired coolies at present unable to procure work. Our contemporary suggests that 300 coolies who were shortly expected to arrive from Madras should at once be sent back in the same vessel that brings them, as the most economical course the Government can pursue, for, owing to the failure of the sugar trade, there is no demand for coolies on the part of the planters, and matters do not seem to be likely to improve.

THE Government of India are so hampered by the Tenancy Bill, that it is extremely unlikely anything will be done this session in the matter of factory legislation. The feeling among mill-owners in Calcutta is that legislation is not needed in their case; but Bombay not unnaturally scouts the idea of any Act being passed which is not applicable to India, as otherwise the Western India Mills would be seriously headlopped. Perhaps another commission may be ordered to assemble to enquire into the working of the mills in Bengal and Upper India. In Calcutta the difficulty often is to get the operatives to work more than three or four days out of the seven, the high wages which they can earn in that period enabling them to "play" for the remainder of the week.

THE Madrassees have good reason to congratulate themselves on the effectual and rapid way in which the repairs to the source of their water-supply, the Red Hills tank, have been carried out; and it is now confidently announced that no further anxiety need be felt about a sufficient water-supply for the city during the coming hot weather. Already it is calculated that there are 912 millions of cubic feet of water stored in the tank, of which fully 600 millions can be made available for the drinking supply of Madras, whilst a further quantity of 200 millions of cubic feet is stored in the Chitaram tank, both amounts being fully equal to a year's supply for the town. The whole of the work of repairing the Red Hills tank is expected to be completed by the end of September.

Selections.

FLOWERS OUT OF SEASON.

THE untimely flowering of trees and shrubs, like the occurrence of the extraordinary gooseberry, is a subject which crops up at such regular intervals, as almost to belie the epithet applied to it. Nevertheless, the very frequency of the comment is an indication that the matter is ill understood.

The ordinary time-rate for the production of new cells, new leaves, new flowers, and so on, varies, as we see, within wide limits. Equally obviously those limitations are imposed by the conjoint effects of inheritance and of external conditions, such as climate or food, or both. An annual plant rushes through its life in hot haste as it were; save and except in the seeds of such plants there is comparatively little building up or maturing of new tissues to be done, and proportionately still less stores of potential food to be accumulated. If, on the one hand, the requirements of such plants are less than in the case of perennials, their exigencies are, on the other hand, more pressing. What they take from the soil, or atmosphere, what power they derive from solar light and heat, must be got quickly, or not at all. One illustration of this is afforded by the paucity of annual species in the Arctic regions or at high altitudes. Neither heat nor light is absolutely deficient in such situations, but the length of time during which they are available is too short to allow annuals to profit by a sufficiently large aggregate of them to mature their seeds. Before they can accomplish their purpose, they are overtaken by frost, and their activity is put a stop to. The energy of perennials, it is true, may be checked in the same manner, but they have been enabled, before the evil day arrived, to lay up stores of nutriment available for use when the increasing heat and light of the following year shall once more quicken their activity. The work to be done is spread over two or more seasons instead of one, and the chances of success are thus correspondingly enhanced. But if we suppose the conditions to be uniformly and continuously favorable, the abrupt cessation of growth will no longer be manifest, the annual will cease to be an annual, the perennial will not die down in winter, the growing points of the buds will not encase themselves in scales, vegetation will be continuous. Such halcyon conditions find their nearest realization in most equatorial climates like that of the Malay Peninsula and adjacent islands. But even there the realization is not perfect. Something happens to disturb the balance; and even the conditions are generally uniform, there is always the idiosyncrasy of individual plants to form a disturbing factor.

such conditions, though favourable to the continuance of vegetation, are less propitious to the establishment of fructification. The formation of stem, leaf, flower, even of fruit, is one thing; the maturation of the seed and of the embryo-plant within it is another; and the conditions propitious to either are correspondingly different. The ripe seed makes in proportion larger demands on the plastic matters formed as a result of metabolism, and has almost invariably the same composition according to its species, but this cannot be said with equal truth of any other part of the plant.

Again, the conditions for growth, that is, mere increase in bulk, are different, in degree at least, from those which favour progressive development or metamorphosis. Speaking in general terms, it may be said that vegetation approaches its end where fructification shows signs of commencement. There is indeed no fixed line of demarcation to be drawn, but while morphologically there are gradations and intermediate forms, physiologically there are also transitions, and periods of instability. It is easy to understand how this happens, and how it is the divergences are not greater. These matters indeed partake so much of the nature of truisms, that some apology might almost be needed for insisting on them, were it not that they are absolutely essential for the due comprehension of the phenomena of untimely blooming.

It is also desirable to draw attention to the fact that there is naturally a wide range in the period during which vital activity manifests itself even in individuals of the same species, and as these individuals vary in colour, stature, &c., even when derived from the same stock, so others may vary in their "timelines." This is specially noticeable in the case of the horse-chestnut, and is perhaps more often manifest in the form of precocious development in spring than in that of tardy growth in autumn. In most cases the plant has to attain a certain age before it produces flowers, but occasionally we find individuals so precocious that they are scarce out of the seed before they burst into flower. A cocoanut has thus been seen in flower while the husk of the fruit was still attached to it. Gardeners, according to their requirements, have freely availed themselves of these individual differences, by selecting for perpetuation late or early varieties. The whole subject of the "chronometry of life," it may here be mentioned, formed the text of a valuable lecture by Sir James Paget, at the Royal Institution, many years ago.

Cases of unseasonable blossoming may be ranged under three heads, according as growth and development are: (1) prolonged beyond the ordinary time; (2) premature or manifested aforetime; (3) renewed after a short interval of arrest. Categories (2) and (3) differ in detail rather than in essence, as will be explained further on.

Taking the cases of continuous or prolonged growth first, it is easy to see that many of them are due to a continuance of favourable conditions. A long spell of summer, without excessive heat or drought, will insure a longer period of blooming; flower will succeed to flower so long as the weather and the natural changes in the tissues of the plant, according to age, are held in abeyance. How small are the exigencies of some plants in these matters, may be illustrated by the fact that there are few days in the year when a daisy or a white dead nettle may not be found in bloom, at least in the southern half of England. It is necessary, however, to introduce some qualification, because one has only to look into one's garden to see that, in spite of apparently favourable conditions, many plants are not to be induced to continue blooming. Although in duration perennial, in the matter of flowering they behave as annuals. Something in their organisation forbids the prolongation of the blooming period. That this is so is at least rendered highly probable by the circumstance that the same reticence is exhibited under cultivation. As an illustration of an opposite character, may be mentioned the prolongation of the blooming period even under relatively adverse circumstances, which has been brought about by the art and selection exercised by the gardener. Take roses, for instance, only one of many that might be cited. Our fathers had to be content with what we now call summer roses, roses of great beauty and exquisite fragrance, but which they must have wept to see "haste away so soon." Now-a-days, the case is very different, there is a whole legion of so-called "hybrid perpetuals" marked in the catalogues of the nurserymen as H. &c. By their agency a second crop of roses is assured, while some will continue in favourable seasons to expand their blooms in succession up to Christmas. This prolongation of the flowering season has been brought about by combining, by means of hybridisation, the robust qualities of European

with the continuous blooming tendencies of the Indian rose. Varieties of pear, the common laburnum, the Wistaria, Feigela, the hybrid *Berberis stenophylla*, some rhododendrons, currants (*Ribes*) exhibit this phenomenon, the flowers being produced on the ends of more or less prolonged shoots, as strawberries, under like circumstances, produce their flowers on the ends of the "runners" of the year.

The premature development of flowers in autumn has a better title to be called unseasonable, because the phenomenon is really due to the unfolding of flowers which, under ordinary circumstances, would remain passive till the following spring. There is not, as in the former case, a new formation or a continuous growth, but merely what the French appropriately call *floraison anticipee*. And here for a moment it may be allowable to call attention to an essay of Linnaeus, entitled *Prolepsis Plantarum*, little read now-a-days, although based on facts, and containing much that is still worthy of consideration. For him a flower was a shoot with lateral outgrowths, a morphological conception that would still satisfy a German transcendentalist. But, further, this shoot and outgrowths were supposed to represent the outcome of six ordinary years' work contracted into one. A flower was, according to this theory, a shoot in which the differentiation parts instead of being spread over six years was hurried

on and completed within one season. For Linnaeus, leaves represented the work of one year, bracts that of the following one, sepals of the third, petals of the fourth, stamens of the fifth, and the pistil, that of the sixth year. It is not necessary to discuss the morphological aspects of this theory, but it is relevant to our present purpose because it emphasises the relation of leaf-shoot to flower—a relation enunciated about the same time, and independently one of the other, by Wolf and by Linnaeus, and thirty years before Goethe, propounded a similar notion. Moreover, it brings into prominence not only the morphological relation of shoot and flower, but one manner in which the time of production of the shoot and of the flower respectively may be varied, a subject having an immediate bearing on the question of unseasonable flowering. If, says Linnaeus (*prolepsis*, § iii.), "a shrub which has been grown in a pot, and has borne flower and fruit every year, be transferred to richer soil in a hot-house, it will produce for many years numerous leafy shoots, but no fruit. From which it may be inferred that the leaves are produced from the same source whence the flowers previously sprang, and so in turn what now tends to form leaves would, by this agency of Nature, be converted into flower, if the same tree were again placed in a pot so as to confine the roots; hence gardeners desirous of obtaining a more plentiful crop of strawberries, cut the fine roots of the plants in spring before they transplant them, in the hope that they will produce more abundant flowers and fruit." Here we see the same principle laid down as that upon which gardeners act when they wish to secure flower and fruit by cutting off the supplies, and thus making the plant, to a greater degree, dependent on the elaborated reserve stored up in their tissues. This is effected by growing plants in small pots, root-pruning, transplanting, ringing, and other processes, all of which tend to diminish root-absorption, and by disturbing the balance between it and other processes, to check vegetation, and in so far to promote the formation of flower. Charles Martin relates the production on a very large scale of inflorescence on the agave, in Algeria, as the direct consequence of the excision of the leaf-buds by a troop of French cavalry, who hacked the plants with their sabres as they passed, and thus, by preventing or checking growth in one direction, stimulated it in another. In like manner I have seen flowers produced on the "suckers" of *Ailanthus glandulosa* when the plant was quite young, on the roots of *Pyrus japonica*, and on a sucker of agave, as the result of injury, probably in all, certainly in some, of the instances.

The frequent production of flowers out of season on newly transplanted trees is accounted for in like manner. But many trees are flowering this autumn which have not been slashed with sabres nor moved by more peaceful weapons. One such tree, a horse-chestnut, I lately (September) saw, in which one limb, and one only, was full of young leaves and flowers, while the remaining limbs were fast losing their foliage. The reason for this partial production of bloom I was not able to divine; possibly it may have had some relation to injury to a certain portion of the root system, in more or less direct connection with the particular branch, but I have no evidence to offer in support of such a guess.

In speaking previously of one modification of unseasonable flowering dependent on activity protracted beyond the customary period, it was mentioned that the flower was in such instances developed at the ends of long slender shoots formed during the course of the summer. In such cases the shoot ends in a flower-bud instead of a leaf-bud, as is usually the case. The conditions are no longer favourable for the extension of the shoot, and the energy of growth is diverted to the production of flower. But in the laburnum, in many fruit-trees, such as the apple and pear, the fruits are normally borne on short thick branches called by the gardeners "spurs." These are very interesting physiologically, as possessing intermediate transitional characteristics, such as those before alluded to, between vegetation and seed-production. In form, these spurs are short and thick, with very narrow interspaces between the leaves, and they bear a cluster of buds which ultimately all develop into flowers, or in which the central and terminal one is a leaf-bud. Internally these spurs are soft and spongy, with a great preponderance of cellular, over fibro-vascular, or woody tissue. The cells are moreover filled with starch. We have evidently here got to do with store-places analogous to that furnished by the tuber of the potato and other formations, in which food, or matter capable of conversion into food, is stored up for future use at the growing points; in this case for the formation of fruit. Flowers are occasionally produced on these spurs out of due season; the flower-bud destined for a following season bursts into activity this year, affording an instance of a true *floraison anticipee*; but more often, according to my observations, when an untimely flower is produced (especially in the apple), it is from the development of a flower in the central bud of the spur, which is usually a leaf-bud, as above stated. In such a case, then, we have not only an alteration in the character of the bud, but a change in the period of its expansion. A converse illustration to that just given is afforded by a case recorded by Mr. Berkeley, in which a bud of a walnut, which in the ordinary course of things should have produced a female inflorescence in the following spring, was developed in the autumn as a leafy shoot.

Renewal of growth after temporary arrest, "recrudescence" as it is sometimes called, occurs normally in the pine-apple, *Eucomis*, *Metrosideros*, and other plants. Abnormally, I have met with it in *Oxycoccus nigricans*, the common wall-flower, *Claothra*, and many others. It hardly differs from the first category mentioned in this note, except in the fact that the new growth is the direct continuation of the old, and not an entirely new lateral formation. It differs from the terminal bud of a "spur," in that the latter is normal as to position, even if developed out of season, whereas in the class of cases now under consideration,

the activity of the growing point, which usually ceases with the development of the last flower, is exceptionally continued.

One other circumstance deserves mention, and that is, the rarity with which true fruit, or at least ripe seed, is produced as a result of these untimely flowers. Sometimes, of course, ripe seed is produced; a plum is before me as I write, the seed of which is as perfect, to all appearance, as that of the first crop could have been. But in the majority of the pears and apples which come under one's notice at this unseasonable period, the fruit is there (in the popular sense), but the core, which is in a botanical sense the true fruit, is absent, or, if present, the seeds it contains are usually abortive. Botanical readers will readily see the morphological reason why, and physiologists will recognize, that in such cases the deviation from the ordinary course is not so great as it appears upon the surface, and the action of the "environment" is not so potent as it appears to be at first sight.

To sum up, these cases of unseasonable flowering appear to be due either to continuous growth and development; to renewal of growth after a longer or a shorter period of arrest; or to the development of a flower-bud in the place of a leaf-bud. What produces these changes? To this no more precise answer can be given than has already been afforded. The absolute nature of the change, structurally and morphologically, depends upon the nature of the inducing causes, and varies accordingly; the degree of change may depend simply on the increased or prolonged intensity of action of the same causes which promote natural growth.—MAXWELL T. MASTERS.—*Nature*.

BET SUGAR-MAKING IN ENGLAND.

THE LAVENHAM EXPERIMENT.

By the end of this month (January), or a few days later, the Lavenham Sugar Factory will be in full work. The delay which has precluded Messrs. Bolton and Partners (Limited) from taking any delivery of beet since the time of harvesting on the farms in October (which must have resulted in a certain loss of saccharine in the roots) has been due to the difficulty of fitting the building with the new machinery in time for the opening of the manufacturing season; and at the present moment it is only one piece of apparatus which is waited for—the whole machinery and plant being supplied by one of the greatest Continental firms, and constructed specially for the novel process now to be introduced. Apart from the exigencies of agriculture in discouraged corn-growing, which may attract farmers to the chances of a new crop, and apart also from the disposition of the railways to accord easy rates of carriage to the factory, there are two special reasons for expecting, even in the face of an unparalleled glut of sugar production, a better fortune for the enterprise than fell to the experience of Mr. James Duncan at the Lavenham factory in 1869 to 1873—one being the progress which has been made in improvement of the beet itself, and the other, the new and economical process of extracting and purifying the sugar. As we pointed out in March last year, the Sugar Association of the Zollverein have developed upon their experimental farm better varieties of beet and improved methods of cultivation, together producing roots richer in sugar and of a higher degree of purity from salts which interfere with the process of sugar crystallization; and by selection and breeding of the plant such an advance has been made also in France, notably by M. Vilmorin, of Paris, that growers can now secure a heavier weight of roots per acre compatibly with the most syrupy quality in the juice.

At the factory there will appear great changes, readily observable to persons who were familiar with the operations of a dozen years ago. The loads of carrot-shaped roots (minus their green crowns, cut off by the growers) will be weighed, but not subjected to any trimming by hand; unless, indeed, a forked and fatty root be dealt with now and then. For, as there will be no rapid rasping grating up the roots into a fine pulp, there is no need for carefully paring off the small rootlets and fibres which used to go away in the drain water—to the clogging and fouling of the brook which flows close beside the factory. And this water-way will not be corrupted and made pestiferous with black char water which used to pour from the charcoal filters, as there will be no such filters. The water-supply will be sufficient, seeing that much less will be required for condensing purposes than upon the old plan; and good water, in addition to that of the natural stream, has been provided by a couple of new wells. The beets, cleansed from adhering soil by the mechanical stirrers and brushes revolving in long vats or washers, will be elevated to the cutter—a machine resembling the root-cutter used by a shepherd—which slices the roots into finger-pieces; and these will be sent down a spout or trough, which delivers a proper charge in turn into each of a series of circular vessels, placed in a ring form of arrangement, for being conveniently charged by the spout as it swings round from the centre like a crane jib. By what is called the "diffusion" process, water of different temperatures at different stages flows continuously through all the vessels in turn, commencing as clear water with each spent charge of beet, and gradually enriching itself with the juice from partly exhausted charges in succession, till it passes, as a rich solution of sugar, salts, and impurities, from the last vessel in which the maceration of the fresh beet is begun. Each of the vessels is emptied in turn of the spent beet, which is carried to the pressing operation, where any sweet syrup remaining is made to exude—the pressed beet, however, still holding enough nutritive material to be an excellent fattening food for animals. This will be loaded upon carts fetching it away at the price of 6s. per ton; that is, half the price formerly paid for the pulp as it came from the bag-presses after the rasp. The solution from the beet will be boiled with lime, which is termed "defecation," and the lime then precipitated by blowing carbonic-acid gas through

the liquid. By the old process there would follow a second defecation, and then the tedious and expensive charcoal filtering. But it has been observed that the mineral earth, strontia, as well as baryta, has the property of being able to seize and enter into combination with sugar in solution. Hence the liquor is boiled with strontia under pressure; a yellowish-white strontia falls as a deposit to the bottom of the vessel; the water, still holding the salts and impurities though it has parted with the sugar, is run out through the precipitate of strontia on a screen upon the bottom of the vessel, and this material is then treated with carbonic acid in water, which breaks it up, separates and recovers the strontia, and leaves the pure sugar in solution, to be concentrated by vacuum pan, and crystallized in the usual manner. The greatest gain of the new process, however, is that, whereas by the old crystallization process the manufacturer lost some 20 per cent of the saccharine matter of the beet juice, which from contamination of salts could not be crystallized and went away in the best molasses—a product of low value—the strontia perfectly clears all the sugar from these impurities in the way of crystallization, and extracts up to 95, or more, per cent of the sugar contained in the beet juice. The improvement has been very widely and rapidly adopted; and Messrs. Bolton, who have mines of strontia and other minerals at Fawler, in Oxfordshire, and at Mondip and Malago Vale, in Somersetshire, where they manufacture the natural sulphate of strontia into the carbonate and hydrate, send large quantities of this material to Germany, Austria, France, and some to Russia and Holland, for use in what is named "the Scheibler process." Baryta had been employed in France, but is objectionable on account of its poisonous properties, which are absent in strontia; and at the suggestion of Captain Sir Francis Bolton, M. Hippolyte Leplay, in France, patented an improved mode of using strontia, by which one operation accomplishes the same result that the "Scheibler" process effects in three. This method of Leplay is the one adopted at Lavenham. The process invented by Dr. Scheibler, of Berlin, is applied on the Continent to treating the molasses; but the process to be used at Lavenham will almost do away with molasses altogether, and the patent includes a cheap method for regenerating the strontia after use, which has been a very costly item in treating molasses.

One advantage of the new manufacture is that it is no longer a matter of prime importance that the percentage of salt in the roots should be small. Common salt, for instance, is an objectionable constituent in the analysis of sugar-beet, because its presence in large quantities betrays an inferior quantity of sugar; but potash in the juice is not objected to, and, indeed, as that article is worth about 24s. per cwt., the sale of the ash resulting, will form a considerable item of profit. Messrs. Bolton and Partners trust to meet the abnormally low price of sugar by the virtue of their process in both enhancing the yield of sugar obtained from the roots and in the various ways enumerated, cheapening the cost of production. There is also this general consideration, that they possess important offsets against the operation of the German bounties, in the fact that they will be able to supply sugar factories in England with strontia at a lower price than that for which the chemical can be obtained in Germany; while it is certain that our home factories will be able to market their sugar at a much cheaper rate than the German sugar can be transported to the same centres, Austrian and German sugar paying some 30s. to 35s. per ton, freight charges, and landing expenses, before it reaches our refineries, and their produce again paying railway freight to the interior.

Coming now to the experience of English growers of sugar-beet, in 1884, we have before us the carefully considered and admirable report of Professor A. H. Church, M.A., F.C.S., late of the Royal Agricultural College, Cirencester. The extraordinary dryness of the spring and summer told very unfavourably upon the germination or regular growth of the plant, and it was not expected that more than half a normal yield of roots would be secured on an average. However, upon 640 acres under the crop, upon 60 farms, the total produce turned out to be about 6,850 tons, or over 10 tons per acre. In some instances the yield was as high as 20 tons; in many cases it exceeded 15 tons, and in a few the produce was so poor as to give less than five tons per acre. On a large proportion of the farms the average was about 12 tons per acre, and the average quantity of sugar in the roots reached about 13 per cent, corresponding to a production of one ton and a-half of crystallizable sugar per acre. Professor Church cites the example of the Rev. R. K. Longden, who, at Brent Leigh, Lavenham, obtained 14 tons per acre of shapely small roots, in drills 16 inches apart, upon clean, well-farmed land, a crop which so managed in an ordinary season would have given at least 20 to 25 tons per acre. Mr. G. H. Nunn, on 11 acres near Bury St. Edmunds, got 18 tons per acre. Mr. Garrett Taylor, on 10 acres near Norwich, grew 14 tons per acre; the roots being 18 inches apart in the rows, averaged, as they should do, less than 14 inches, and were consequently very rich in saccharine, giving 14½ per cent of sugar. Had the spaces been only nine inches between plant and plant, there would have been double the number of plants and a marked increase of sugar per acre. Great stress is laid upon the importance of cleanliness from weeds, especially couch-grass, of thick sowing, early thinning, careful singling, earthing up exposed parts of roots, cutting off any "bolted" or runaway stems, selecting the proper time for pulling the crop, and drawing without wounding the roots. And Professor Church recommends manuring with nitrate of soda as well as with superphosphate of lime, though farmyard dung ought to be applied to the crop preceding the sugar-beet. Where this has been used directly, especially in the spring, the roots are uneven in size, coarse in quality, and much fanged.

It appears that trial crops have been grown during the past year in Surrey, Berkshire, Oxfordshire, Middlesex, Northamptonshire, Lincolnshire, Staffordshire, Worcestershire, Warwickshire, Suffolk, Norfolk, Cambridgeshire, and Essex, also in Wexford in Ireland.

The year's crops by no means offer a series of exceptionally well-grown and rich roots; yet in only four cases does the percentage of sugar fall below 11; in seven instances it is between 11 and 12, in eight cases between 12 and 13; in eight cases between 13 and 14, in seven cases between 14 and 15, and in three cases between 15 and 16·4 per cent. It is encouraging to hear that the highest percentages of sugar are not generally associated with the smallest yields per acre. Professor Church attributes most of the instances of only moderate success to the farmers treating sugar-beet as a fallow crop and to their neglecting the instructions given for management; and he adds an important note on the value of the beet (not the pulp from the factory, but the root itself) as cattle food. He says:—

"Several of the farmers who have grown these roots have been glad to use a part at least of the crops for feeding their stock; the results have been most satisfactory. Chemical analysis explains the superiority of sugar-beet over other roots for feeding purposes. While mangolds commonly contain 90 per cent of water, and swedes and white turnips often more, sugar-beets will generally be found to average about 81 per cent. Thus a crop of sugar-beet, even though its gross weight may not be much more than one-half that of other kinds of roots, will contain quite as much solid nutritive matter. Moreover, it will present the further advantage of containing less of those saline matters which, without being of use in animal nutrition, tend, by their removal from the soil, to its exhaustion."

It is necessary to state that Messrs. Bolton and Partners have requested their clients, the growers by contract, to defer taking any action towards sowing for the ensuing season until the close of February, when the experience gained by actual working in the factory will enable them to make important decisions for the future. An impression prevails that because of the unlooked-for fall in the sugar market, the enterprising company will not be able to pay a good price for roots. But in any case they will certainly perform their contracts for the present crop; the terms, we understand, having been 20s. per ton for roots delivered at the time of taking up, and 22s. per ton when, as in the present case, the roots have been clamped. The proposal now under consideration is to fix the selling value of the crops of 1885, and future years, according to the quantity of sugar yielded per acre; and it is probable that strict adherence to the scale will bring out some crops worth, if reckoned by weight of roots, up to 20s., and others down to, perhaps 16s. per ton. Messrs. Bolton and the influential members of their company contemplate the eventual extension of the sugar-beet industry in many suitable districts of England if the commercial results of the Lavenham trial prove encouraging; and it is very well known that for depth and fertility of soil the Lavenham district has no especial advantage. Indeed, as shown by the comparatively yielding of common mangolds, some tracts of land are capable of producing under similar arrangement one-third, or even one-half, more weight of roots per acre than can be grown on most parts of the area which has been under sugar beet in 1884.—*Times*, January 24, 1885.

LIME.

By DR. ANDREW P. AITKEN,

Chemist to the Highland and Agricultural Society.

LIME is found in the primitive rocks in combination with silica, forming silicates. During the process of weathering the silicates are decomposed, and the carbonic acid of the atmosphere unites with the lime to form carbonate of lime, which is insoluble in water; but it is capable of uniting with an additional quantity of carbonic acid, so as to form the bicarbonate of lime, which is soluble in water, and which, when washed down into the rivers, gives to the water that character which is called *hardness*. There are other salts which cause hardness in water, but the bicarbonate of lime is the chief of them. Hard waters are usually clear, because they do not dissolve the vegetable matter out of the soils through which they flow; while waters which contain very little lime-salts are soft, and when passing through the soil extract from it much vegetable matter, and become brown coloured. Bicarbonate of lime, as found in water, is easily decomposed; the half of the carbonic acid escapes from it, and there is left behind the carbonate of lime, which, being insoluble in water, is precipitated. When this goes on on a large scale, extensive sediments of carbonate of lime are deposited, and these in course of time form the limestone strata which abound all over the world, and which, though originally formed under water, are frequently found thrown up into great mountain ranges. When limestone is heated red hot in a current of air, the carbonic acid is entirely driven away from it, and lime is left behind. This is the process which is carried on in lime-kilns.

The product is variously named lime-shell, hot lime, burnt lime, caustic lime. By this heating process the character of the mineral is entirely changed, from being a mild, indifferent substance it has been converted into a strong base, that is to say, a substance which unites powerfully with acids, neutralising them, and forming lime-salts. If it combines with carbonic acid it is re-converted into carbonate of lime; if with sulphuric acid, it forms sulphate of lime, a substance which is slightly soluble in water, and is found in nature in large quantity as gypsum. When water is poured upon lime shell, a violent union takes place, accompanied with a great rise of temperature, and the stony mass crumbles down into a fine powder, the hydrate of lime, which is known as slaked lime, and which, when pure, is completely soluble in water.

Lime in some form is essential to the growth of plants, so that a soil which contains no lime cannot grow a crop. The amount of lime required by plants is not very great, and it is frequently found that fertile soils contain very little of it. Lime exists in the soil chiefly as carbonate, and as that is the commonest of lime-salts, it is very often spoken of as lime, but, accurately speaking, the name lime should be applied only to caustic lime, which is the base of all lime-salts.

When caustic lime is exposed to the air, it takes up moisture, and crumbles down. Thereafter it soon absorbs carbonic acid, and becomes converted again into carbonate of lime. In such a case all that has been achieved by burning the limestone is an alteration in its physical character. It has been changed from a hard, and perhaps crystalline mass, into a soft, fine powder, easily mixable with the soil, and easily soluble in water containing carbonic acid.

Caustic lime, on account of its solubility, is able to soak through the soil, and travel some little distance in search of acids. The acid which is most abundant in the soil is carbonic acid, which is one of the products formed during the decay of organic matter. About half of the total substance of dry vegetable matter consists of carbon, and in the process of decay this carbon is mostly given off as carbonic acid. The more rapidly the carbonic acid is got rid of, the more rapidly does the rotting process go on. It thus occurs that when a soil contains too much organic matter, as in the case of moss and bog land, the application of lime is found to be of great benefit, because by uniting with the carbonic acid present in too great quantity in the soil and precipitating it in the form of carbonate of lime, it makes room for the formation of more carbonic acid, and thus rapidly increases the rotting process, and reduces the excess of organic matter. There are other acids formed during the decay of organic matter, and with all of these lime unites, forming either soluble or insoluble salts. The former are washed down through the soil, and the latter are precipitated in it. Accordingly, when land has become 'sour,' as it is called, lime is the substance that is required to 'sweeten' it.

The souring of land is due to various causes, and the acids which produce sourness are of various kinds. There are salts contained in fertile soils which are decomposed by the roots of plants, but are not entirely absorbed by them, and when the plant absorbs the base of the salt, and leaves the acid behind, the soil becomes soured. Thus, in the case of potash salts, such as the sulphate and muriate of potash, there are presented to the roots of the plant the base potash, which is much required by the plant for the formation of its wood, while the sulphuric acid and muriatic acid are of comparatively little use; and if the plant absorbs the potash, and leaves the acids behind to form compounds with weaker bases, the land becomes soured from the presence of salts having an acid character. When a strong base such as lime is applied to such a soil, it unites with the sulphuric and muriatic acids, and neutralises them, forming the sulphate and muriate of lime, both of which are soluble salts, which are easily washed down through the soil. But the chief cause of souring in land is the formation of organic acids during the too slow oxidation and decay of organic matter. These organic acids especially accumulate in wet soils, where the oxygen of the air is prevented from getting easily at the organic matter to convert its carbon rapidly into carbonic acid and its hydrogen into water so that there are formed intermediate substances, consisting of various combinations of carbon, hydrogen, and oxygen, which are known as organic acids, such as humic acid, and these are injurious to the roots of plants. When lime is applied in such cases the acidity is neutralised, and as the products of decay are removed, the land becomes 'sweetened,' and the rotting of the organic matter goes on with renewed vigour.

If the acids which are present in the soil, or are formed in it, were all of an injurious character, the application of lime would be an unmixed benefit; but this is by no means the case. One of the most valuable constituents of a fertile soil is nitric acid, which is formed by the oxidation of the nitrogenous part of organic matter, and it is of great importance that the store of it contained in the soil should be husbanded as much as possible. It is a soluble acid, and all its salts are soluble, and as it is being constantly formed in the soil, the probability of its being washed down through the soil and carried away by the drains is very great. Recent discoveries which have been made regarding the formation of this valuable material have invested it with a very special interest. Its production is found to be correlated with the life and growth of exceedingly minute organisms, which abound in fertile soils; and the investigation of its formation and history in the soil, which is being carried on by Mr. Warington, at Rothamsted, forms one of the most interesting contributions to the science of agriculture. Analyses of the drainage waters on the Rothamsted farm show that nitric acid is being lost to the farm at all times, and the circumstances which affect the amount of that loss will be again referred to.

When lime is applied to a soil, it combines with the nitric acid in it, forming nitrate of lime, and by so doing gives a fresh impulse to the nitrifying process. If the increased production of nitric acid, thereby occasioned is in excess of the wants of the crop, or if it occurs at a time when there is no crop on the ground, there is nothing to prevent the passage of this valuable material downwards through the soil and subsoil and into the drains, where it is lost to the farm. The only thing which can arrest nitrate of lime or other nitrates in their downward course is the roots of growing plants. These absorb it, and bring it up to the leaves and growing parts of the plant, to be converted into albumen, that most valuable constituent of fodder. It is therefore obvious that one unfortunate result of liming may be to encourage an excessive or ill-timed production of nitric acid, and a consequent loss to the fertility of the soil. Caustic lime, when applied in large quantity, is not favourable to the life of nitrifying germs—it is rather destructive to these minute organisms; but as soon as the lime has lost its causticity, that is to say, as soon as it becomes converted into carbonate of lime, by uniting with the carbonic acid in the soil—its presence in that mild form is favourable to the process of nitrification.

But there are occasions when a caution is needed, and when the application of caustic lime is of special benefit, viz., where the surface of the land has become fouled by the growth of moss and feeble annual weeds. The strongly alkaline action of caustic lime

CALCUTTA :—SATURDAY, MARCH 14, 1885.

[No. 11.]

Crop and Weather Report.

[FOR THE WEEK ENDING THE 4TH MARCH, 1885.]

General Remarks.—Slight rain has fallen in most districts of Bengal and Assam. In the North-Western Provinces local showers have occurred, and there has been some rain in parts of the Madras Presidency and the Central Provinces, and in the Jullundur District of the Punjab.

There is no change to record in agricultural operations in Madras, and in Mysore the state of the crops continues generally unfavourable. In Coorg the rice crop is being threshed. In the Bombay Presidency, the Central Provinces, and the Berars, the *rabi* crops are being reaped, and prospects are good.

In the Central India and Rajpootana States and Hyderabad, the standing crops promise well and prospects are favourable.

The prospects of the *rabi* crops in the Punjab and in the North-Western Provinces and Oudh are generally excellent.

In Bengal the *rabi* crops are being reaped, and a good outturn is expected. Ploughing for next season's rice crop and pressing of sugarcane are in progress. In Assam prospects are favourable, and ploughing continues.

Cholera is abating in the Madras Presidency; small-pox is prevalent in Burmah, and is reported from most other provinces; in other respects, the public health is fair.

Prices are generally steady.

Madras.—General prospects fair, except in part of Bellary and Anantapore.

Bombay.—*Rabi* harvest continues in parts of 11 districts; standing crops injured by mildew, blight, and frost in parts of Hyderabad, and by rust and blight in parts of Shikarpore; scarcity of fodder and drinking water continues in parts of Belgaum and Dharwar; cholera and cattle-disease in parts of 7 districts, small-pox in parts of 9, and fever in parts of 13 districts.

Bengal.—Some rain fell mostly in the districts of the Presidency, Dacca, and Chittagong Divisions; it has facilitated ploughing of land for next season's crops; *rabi* crops are being harvested and promise a good outturn; *dahia* crop in Orissa is doing well and is in ear in some places; pressing of sugarcane is going on; price of rice almost stationary; cases of cholera and small-pox are reported from some places, otherwise public health good.

N.-W. Provinces and Oudh.—Showers have fallen in a few districts; some injury to *rabi* from rust and insects, but crop prospects are favourable; prices steady, and public health good.

Punjab.—Health and prospects good; prices falling in Peshawar, and generally stationary in other districts.

Central Provinces.—Weather getting hot; *rabi* harvest continues; prospects favourable; prices steady; fever, small-pox, and cholera in parts.

British Burmah.—A few cases of cholera in Akyab district and Rangoon town and in Thonogwa, Hensada, Amherst, and Shwegyin districts, but nowhere severe; small-pox more or less prevalent in parts of Akyab, Tharrawaddy, Bassein, and Hensada, Thayetkayo town and Moulmein, chiefly sporadic; cattle-disease in Tharrawaddy, Bassein, and Thonogwa districts, but not serious, otherwise public health good; weather sultry.

Assam.—Mornings and nights still cool; days perceptibly warm; mustard almost gathered; ploughing operations for *aus* going on. State and prospects of crops as before; small-pox reported from the Sudder sub-division; public health otherwise good.

Bihar and Coorg.—Reports regarding state of crops generally unfavourable and prospects of season indifferent; drinking water and fodder for cattle scarce; public health fair; prices rising in parts.

Berars & Hyderabad.—Weather clear; days getting warm; prospects favourable; *rabi* crops being harvested; wheat 22 and *jowari* 26 seers per rupee.

Central India States.—Weather seasonable; prospects of *rabi* and opium good. Health good.

Rajpootana.—Crop prospects favourable; prices steady; health good.

Letters to the Editor.

WHEAT IN INDIA.

TO THE EDITOR.

SIR,—You have suggested the application of nitre as manure to increase the produce of Indian wheat. The recent experiments on wheat with different kinds of manures, especially those conducted at Rothamsted, have brought prominently to the notice of the English farmers the very great value of nitrogenous manures, and advantage of this should certainly be taken by the Indian cultivator to increase the produce of his wheat crops. But the subject is not so simple as may be imagined. It is true that the application of nitre or ammonium sulphate will double, and may treble, the produce of wheat, but there are risks in its application which must be guarded against, or failure will result. What those risks are, I shall make an attempt, with your permission, to show. We have certain wealth stored in the soil, finite and determinate in quantity, which forms a capital from which we cannot go on drawing with impunity. Now what nitrogenous manure does, is simply to enable us to make heavy drafts on this latent wealth in the soil. It serves as a stimulant to make the soil give up more of its fruits, but at the expense of future productiveness. It is well perhaps for India that the secret is not generally known, or with the system of cultivation pursued in this country, the exhausting process would be in full swing. In England, farmers as a rule are bound by express contract to follow a prescribed system of cropping, and the landlords there possess the requisite knowledge to understand the value of different systems of farming. A little knowledge is a dangerous thing, and I have no doubt this little knowledge of the secret of nitrogenous manure in wheat would be dangerous in this country; and I cannot too strongly protest against the use of this manure to any large extent. Half a *manad* of country nitre, as recommended by you, is certainly not a very large dose for a bigha of wheat, but the fear is, and a reasonable one, that the ryot will not stop at half-a-manad, if he should find, as in the beginning he will undoubtedly do, that this application is attended with a marked increase in the yield of the crop, and it is this fear which prompts me to warn the people against the abuse of this stimulating manure. But a greater risk in the use of this manure is still to be mentioned. The character of Indian wheat needs improvement, and it will become worse if grown with the help of nitrogen. Its quality will deteriorate, and the trade accordingly suffer. The recent analyses of Indian wheat, made at the instance of the India Government, have prominently brought to the notice of the public at home the superiority of Indian wheat for the miller. Now this quality will be seriously impaired by growing it with nitrogen. At present, an attempt should be particularly directed to two things—1st, to the better dressing of the corn for the market, and 2nd, to maintaining the present quality of the sample, if not improving it. On the first point, viz., the dressing of the corn for the market, I shall write a separate letter, in which the safest mode of increasing the produce of the crop will also be discussed.

S. H.

NOTE.—We shall be very glad to hear from our correspondent again.
—ED., I. A.

PROSPECTS OF TEA IN DARJEELING AND THE DOOARS FOR 1885.

TO THE EDITOR.

SIR,—The past month has seen the close of pruning. Managers are now, during their leisure time, repairing coolie lines, making mate, *chalntes*, *topkries*, etc., for the coming season. Labour is plentiful. Want of rain is telling on the young plants in the light-soil.

lands, and in some spots the old plants look sickly. It is not expected that we shall have an early season, unless we have rain during the next fortnight. Estimates on old gardens are not in excess of last year, as it is found there is a slight deterioration on old plants year by year, necessitating the cutting down of old bushes, or heavy manuring; the latter process, unless some new and cheap remedy is found, is not profitable. There is no doubt the soil is becoming poorer year by year. Hence it is believed that this is the cause of our teas not being so good as they were in days gone by. If planters would utilize their women and boys in carrying fresh soil and manure on parts of their gardens year by year, in the winter season, or dig up the level gardens and mix this soil with a certain amount of chemical manure, there is little doubt that they would get a larger out-turn, and increase the quality of the tea at but a small expenditure. The pests—red spider, moth, green fly, and mosquito blight—are much dreaded by planters, and many an estimate and planters' reputation have been ruined by them. A remedy in the way of an insect poison, that has neither taste nor smell, was successfully used last year by a person in the Darjeeling district, and we believe the remedy can be obtained in the shape of a powder in tins, at the "Indian Supply Association," 10, Dalhousie-square. This remedy, we hear, is not a total cure, but checks the pests, and diminishes the ravages of the mosquitoes and greenies to a point which is nominal. We read Mr. Cruikshank's speech of last week in the newspapers; and we think that the tea-agents should set the good example by reducing their commission by at least 1½ per cent; this would help the gardens considerably. There is an old saying—starve a horse, and he won't gallop. This we might apply to coolies; if they are well fed they can work well—but if fed and paid badly, they will not do much work. It is better to pay a trained and acclimatized coolie a small bonus, than to get up a raw man from his own country. The supernumeraries attached to a garden are often useless. This should be looked to. Managers are often insufficiently paid. They risk a great deal in a bad climate, and it is a very rare thing to ever hear of a planter retiring. Many go home, and many go home to die. Did any one ever see a tea planter who has lived in the plains all his life 50 years old? It is proposed at home to increase the duty on tea. If they do, we shall be the people to suffer. If England wants the support of her colonies, she must put a duty of 1 shilling per lb. on China tea. India can give England enough tea for all her wants, provided the duty is not raised.

R. RECNEPS.

WHEAT-GROWING.

TO THE EDITOR OF THE TIMES.

SIR,—It will interest many readers to know that Major Bell, the projector and present worker of the great Canadian wheat farm of 100 square miles, is now in London on a short visit. At the recent expedition of the British Association to Canada, those of its members who got so far west were entertained at the Bell Farm, and were driven over the great plains of wheat which were then on the point of being harvested. The facts witnessed were seen to have an important bearing upon the supplies of wheat for our people in England, and upon the chances of those of our farmers who still propose to grow cereals or pulse.

Last autumn I devoted a long holiday of two months chiefly to visiting the farmers who are now dotted about upon the vast alluvial plains of North-West Canada. I spent a week in wandering about at the end of the track of the Canadian Pacific Railway in the Rocky Mountains of British Columbia; I spent another week in the city of Winnipeg; I went about among the still living old Scotch settlers who went out with Lord Selkirk, and who still crop their original farms upon the beautiful banks of the Red River, where he so wisely located them; and, among other places, I visited the Bell Farm. I have also had the advantage of prolonged conversations with Major Bell during his present visit to London. The Major tells me that he would gladly attend any meeting to give an account of his agricultural operations and to answer inquiries; but as only a few people can hope to come into personal contact with him, I may, perhaps, shortly call attention to the data with which we are now furnished.

The Bell Farm contains 100 square miles of rich alluvial land practically all fit to put the plough into, and perfectly unencumbered by timber. Its location is in Assiniboia, upon the Canadian Pacific Railway, 312 miles west of Winnipeg. It has its own railway station, which is known as Indian Head, and the whole of this land is being rapidly brought forward for wheat-growing—the school and public building sites only excepted. At the railway station is an elevator where the grain is lodged and from which it is delivered into the railway cars—each car-load being 600

bushels and weighing 30,000 pounds. The wheat is sold by the bushel of 60 pounds weight, and not by measure, inasmuch as large quantities of wheat can be weighed out much more easily than they can be measured. Some of the wheat grown on the Bell Farm has weighed 66 pounds per bushel, but in such case the farmer has the advantage of selling by weight. With poor wheat he would have to bear the disadvantage. Comfortable houses are already built for the labourers; the Major and his family have a handsome residence such as would satisfy a gentleman farmer in England. The horses and cattle are properly housed; a perfect system of book-keeping shows every detail of the expenditure and other produce; and there are around the Major a number of active young fellows—his pupil-assistants—who are learning to farm with a view to start for themselves at the end of a year or two.

During the 1884 season the Bell Farm has raised 130,000 bushels of grain, and there have been in crop about 6,000 acres. The acreage in crop and the produce of the season 1885 are expected to be double those of last season. The cost of the wheat thus grown has to-day been kindly written out for me by the Major. The figures are in decimals of a Canadian dollar—i. e., in cents, of which 100 are equal to 98.6 English halfpence. The cost as given below is per bushel of 60 pounds weight, delivered from the Bell Farm elevator upon the railway station at Indian Head. It is as follows:—Labour, \$'07; horses, \$'036; maintenance of labourers, &c., \$'033; cost of seed, amount written off capital account for depreciation of horses, implements, stock, &c., and 8 per cent upon the purchase money, &c., of the land in crop \$'20; total, \$'34.

Now, multiplying the 34 cents by eight we get the net cost per quarter of the wheat as 272 cents. This is 11s. 2d. English money. But this is wheat receivable from the elevator at the Indian Head railway station, 312 miles west of Winnipeg, and we have to provide for its transport to England, a distance of 5,000 miles. The cost of transport from Indian Head to Liverpool during the last year has been, Major Bell tells me, 11s. per quarter, and during the coming years the same rate of freight is expected to rule. This, then, makes the fine hard red Manitoba wheat deliverable in Liverpool so as to pay 8 per cent in capital invested in land in North-West Canada, so long as wheat shall not fall below 22s. or 23s. per quarter.

It is obvious that, as soon as these facts are realized by English farmers, they will begin to consider whether they shall struggle along and lose money in attempting to grow cereals and pulses in England, or whether they shall take their capital, found themselves new homes in this great Canadian territory, and grow rich. To our idlers at home who have been living upon rents derived from arable land, the facts are not less interesting. To them it means a denudation of which no adequate conception has yet dawned upon their minds. They will have to work or to starve. It is hardly too much to say that these facts mean a silent but inevitable revolution in the position of the territorial aristocracy of England.

It behoves me to add some words more. In all my cross-country wanderings in this great North-Western territory—one railway taking me more than 1,000 miles in a direct line over unbroken alluvial plains—I never met one man who deserved to succeed who had not had a real and substantial success. Loafers, idlers, and drinkers go to the bad there rather more quickly than at home. It is not a place for feeble, worn out, or aged people to go to. Speculators will only make fortunes if they have large capital and the wit to invest it wisely; they will not make fortunes because the Canadians are fools by the side of raw English colonists. But the healthy, respectable English farmer with a few hundred pounds, who settles down with the intention to work and to do his duty will be sure to succeed. He will grow rich ultimately as the country advances, in some cases very rich, and will live a comfortable, free, and happy life. No country in the world is healthier than these great alluvial prairies.

Just now every emigrant over 18 years of age is entitled to a half-mile square of this beautiful land on paying a survey fee of two guineas. He is entitled also to pre-empt the adjoining half-mile square on gradual payments amounting to 10s. an acre. And as on bringing this fairly under cultivation the Government returns 5s. an acre, it will be seen that for the sum of £42, the emigrant begins with a freehold from half-a-mile deep and one mile long. Three hundred pounds will build a wooden house, provide implements, and oxen, and keep the emigrant and his family till the crops are harvested, and thenceforth he begins to save money every year.

JAMES EDMUNDS, M.D.,

Medical Officer of Health for St. James's, Westminster.
Grafton-street, Bond-street.

Editorial Notes.

IN connection with the agricultural crisis at home, a large meeting, principally composed of East Essex farmers, was held at Colchester, under the presidency of the Mayor, to consider the present critical condition of agriculture. It was resolved to send a deputation to the Prime Minister, and also to Sir Stafford Northcote, with reference to the crisis. Among the speakers were Mr. J. Round, M.P., the Hon. C. H. Strutt, M.P., and Mr. R. K. Causton, M. P. On the suggestion of Mr. Causton, a committee was appointed, with instructions to draw up a statement, showing what it considered the best means of remedying existing difficulties. The committee was further instructed to report to an adjourned meeting, to be held in a month. Mr. Causton remarked that he thought it hopeless for farmers to ask for a return to protective duties on corn. Suggestions that tithes should be abolished were received with cheers.

IN India, owing to climatic influences, and the ignorance of the masses in regard to the elementary principles of chemical science, milk, that necessary of life for the million, hardly keeps good for even a few hours after it is drawn from the cow. It is otherwise in Europe. By the latest accounts we hear that, under the presidency of Mr. Kappeyne van de Coppello, a lawyer, of Amsterdam, a meeting of nearly a hundred farmers and persons engaged in industrial pursuits has been held at Hoorn, in the province of North Holland, to discuss the project of Messrs. Scheuer, from Amsterdam, and others, for the establishment of a London Dairy Supply Association. The intention is to build four ships, of 720 tons each, which will convey daily 100,000 litres of fresh Dutch milk to Harwich, from Amsterdam, whither it would be brought in ice-waggons of the Dutch Railway Company, and ice would be also employed in the carriage from Harwich to London. The *Société Anonyme* would have a capital of 1,700,000 guilders, and its promoters urge that if only 100,000 litres of milk could be sold in London at the price of 2½d. per litre, there would be a revenue of 412,500 guilders per annum, or 24 per cent upon the capital. With a supply of 150,000 litres daily, the revenue should be 1,620,050 guilders, or more than 57 per cent. The milk would always be dispatched without mixture of water, by special trains, and sold to a certain number of agents in London, who would sell it in smaller quantities at far lower prices than are at present charged. Before commencing the enterprise, the meeting—which expressed itself disposed to entertain the views of the association—decided to appoint a committee to ascertain how long the milk at different temperatures will keep good. The enterprise appears likely to be carried out.

A most interesting paper has just been published by the Madras Government on the use of the coca leaf as an anæsthetic. Messrs. Hind & Co., of Calicut, had sent to Mr. Logan, the Collector, a small quantity of what is considered in London a superior sample of prepared Coca leaves valued at 10s. per lb., and asked for full and reliable information in regard to the best and simplest process for preparing the leaf for market. All that they know at present on the subject is that the leaves should be prepared almost in the same way as tea—only not rolled,—fermented and then kiln-dried. Mr. Logan says that both Mr. T. J. Fergusson and he have well-established plants of *Erythroxylum coca* in their gardens; that the plant seems to thrive admirably in their gardens, that it seeds freely, and is easily propagated. From an article in the *Morning Post* of the 3rd December last, it appears that what seems to be an exceedingly important discovery has been recently made by an Austrian physician. It has long been known that the leaves of the coca plant contain an active alkaloid, but it has been reserved for Dr. Koller of Vienna—though of course the originality of the discovery is already in dispute—to find that it operates as a powerful local anæsthetic. In the United States it has been used with complete success in ophthalmic surgery, and has also been employed for operations on the mouth, ear, and throat. There seems to be no discomfort what-

ever connected with its application, and the particular surface affected is made completely insensible to pain without any loss of consciousness on the part of the patient. In the case of the eye, the mere introduction of a few drops of the solution is sufficient to produce anæsthesia for something like half-an-hour, and severe neuralgia is said to vanish before it. It has thus far been little used in this country, partly, perhaps, from the difficulty and cost of obtaining it, for the supply is not equal to the present demand, and it fetches half-a-crown a grain. But we may assume that it will soon be imported in sufficient quantity, and that it will be found, as one of our medical contemporaries prophesies, an exceedingly important addition of our therapeutic armoury.

"WHEAT IN INDIA" is the title of a paper just issued by the Government of India in the Revenue and Agricultural Department. From statistics supplied by the Government and heads of the several Provinces in which wheat is grown, it appears that there has been a great falling off in the area under wheat in the Central Provinces—4,179,982 acres in 1881-82, and 3,619,701 acres in 1882-83, but the former figures are not considered reliable. "Wheat is very little grown in Madras, Ajmere, Assam, and Bengal (except Behar). The average area under wheat in India is about 26 million acres, and the average gross production is nearly seven million tons. Wheat is raised under extraordinary diversity of conditions. In the North-Western Provinces and parts of the Punjab, manure and frequent waterings are thought essential to secure a good crop. In the northern districts of the Punjab, the winter rains obviate in a great measure the necessity for irrigation, while in the Mooltan country and in Sind the wheat crop depends on inundation canals drawn from the snow-fed rivers. In Rajpootana what little irrigation exists is obtained from tanks and catchment basins, and the finest crops are sometimes seen in the dried-up beds of these reservoirs. In Central India and the Central Provinces and parts of Bombay the moisture-holding cotton soil, which everywhere predominates, and a heavier rainfall enable the cultivator to dispense with irrigation. The cultivation is in these tracts far less careful in character than in Northern India, and both the cost of production and the outturn is less. In the Punjab wheat appears to be most extensively grown in the districts of Ferozepore, Rawul Pindie, Sealkot, Lahore, Hoshiarpore, Jhelum, Umballa and Guzerat; of the total imports in 1883-84, 3,50,829 maunds were from the North-Western Provinces and Oudh. No wheat was imported by river. In the year 1882-83, 2,40,082 maunds of wheat were sent to Howrah, and an almost equal quantity in 1883-84. In the former year 2,18,897 maunds of wheat were forwarded by rail to Bombay, and in the latter year, 14,33,676 maunds. Nearly all the traffic went by the Rajpootana route. The amount of wheat that comes to Calcutta from the Punjab is insignificant, compared with the exports to Kurrachee; Sind taking 33,67,354 maunds. The Deputy Commissioner at Sukkur, who registers the Indus boat-traffic, is unable to account for the considerable increase of wheat which went down the Indus from this province in 1883-84. Nearly all the wheat must find its way to Kurrachee, whence it is exported to Europe. The following extracts from the review by the Government of India in the Financial Department on the accounts of the Sea-borne Foreign Trade of India for 1883-84, however, explain, in a great measure, the cause of the traffic in wheat between the Punjab and Kurrachee being so brisk: "The considerable increase in the imports into Sind was due mainly to the great stimulus given during the year to the export trade in wheat and seeds, which attracted shipping in larger numbers than had ever been seen before in the port of Kurrachee. The extension of the British settlements in Baluchistan also led to a larger demand for goods, which reached consumers in those parts more conveniently from Kurrachee. The augmentation (in exports merchandise) in Sind was extremely large owing to the demand for wheat and seeds, especially the former, Kurrachee having become, with the completion of the line of railway, the great outlet for Punjab wheat."

THE total import of wheat by rail into the North-Western Provinces and Oudh were 2,61,535 maunds as against 3,70

maunds in 1882-83. There was a decrease in the imports from the Punjab and an increase in those from the Central Provinces. As compared with the year 1882-83, there was an increase of nearly 34 lakhs of maunds in the export of wheat which is accounted for by the fact of a large demand from Europe in consequence of the unfavourable prospects of the red winter wheat in the United States. Calcutta still takes a greater share of the exports than Bombay, though the latter has been brought into closer connection with the western half of these provinces by the opening of the Rajpootana-Malwa Railway. The main granaries in these provinces for export purposes are Oudh, Meerut, and Rohilkhand. Wheat trade is also carried on with the foreign countries of Thibet and Nepal. The quantity of wheat imported by rail into Beugal was 72,56,557 maunds against 45,19,020 maunds in 1882-83 and 49,24,795 maunds in 1881-82. During the past year an impetus was given to the trade in wheat in consequence of the freight by sea from Calcutta being very low, and that by railway having been reduced in 1882-83. Exporters were thus able to compete on better terms with America in the London wheat market. Eighty-three thousand six hundred and ten maunds of wheat were imported by rail into the Central Provinces. The exports were 77,08,223 maunds against 57,13,093 maunds in 1882-83. Of the total wheat exported, more than half was sent from the Nerbudda block, which is fed by Saugor and the foreign territory lying beyond. This block is at present the most important wheat-producing area in these provinces. Wheat is largely cultivated in the districts of the Nerbudda Valley and in those in the extreme north of the provinces. It is also extensive in the Satpura hill region, and in the Wardha and Nagpore districts to the south-west of it. There is little or no cultivation in Nimar and the other parts of the province. Mr. Fuller, writing in 1882 on the subject of wheat cultivation in the Central Provinces, stated that "the thinness of population and consequent large extent of individual holdings offer more inducement to low farming on a large, than to high farming on a small, scale. The outturn of the land is actually far smaller than in more crowded tracts, whilst the surplus produce per head is considerably larger, since the poorer the cultivation the larger is that proportion of the produce which results from natural forces as opposed to the labor of the cultivator." He further remarked that the large export trade of the Central Provinces "lies, not so much in the productive power of the soil as in the scarcity of the population which derives its food from it." A very large proportion of the exports was taken by the Bombay port, the main outlet for these provinces.

.

In the Bombay Presidency wheat is most extensively raised in the districts of Kandeish, Nasik, Ahmedabad, Ahmednuggur, and Dharwar. No wheat is grown in Ratnagiri, Kolaba, and Kanara. The largest imports are from the Central Provinces and the Punjab. Most of the wheat trade with the Bombay port was as usual monopolised by the former province. The Punjab also had considerable dealing in this respect with the port, but it imported as much as 3½ lakhs maunds from the North-Western Provinces and Oudh. In addition to the 1,03,43,337 maunds shown as imported from external blocks into the Bombay port, 17,85,951 maunds came from the internal blocks of the presidency to the port for shipment to Europe. The total quantity imported by rail into the presidency aggregated 1,04,69,057 maunds against 98,52,382 maunds in 1882-1883. The wheat imports by road into Bombay aggregated 5,84,470 maunds against 8,46,382 maunds in 1882-83. This great falling off is due to the rainfall being excessive and unseasonable. The wheat exports by rail were 40,619 maunds, and those by road 77,844 against 24,40,761 maunds and 71,224 maunds, respectively, in the preceding year.

.

In Sindh, Shikarpore is the only district in which wheat is grown to any considerable extent. The trade, as at present registered, is with adjoining native States, viz., Bhawalpore, Jessulmeer, Jodhpore, Khairpore, Cutch, and Gujarat. Arrangements have now been made for registering the rail-borne and river-borne traffic between Sindh and the Punjab. This is a step in the right direction, as the trade between these two

provinces is becoming very extensive, 33,67,354 maunds of wheat having been exported by rail and 15,95,221 by river from the Punjab to Sindh (Karachee). The foreign export trade of Sindh has recently been very active. Last November 7½ lakhs maunds (547,305 cwt.) of wheat were shipped from its ports against nearly 5 lakhs maunds (346,252 cwt.), during the corresponding month in 1883.

.

In Berar 6,706 maunds were imported by rail and 1,11,974 maunds by road as against 1,748 and 12,60,186 maunds, respectively, in the preceding year. The falling off in the road-borne trade is attributed partly to the exceptionally wet season of 1883-84 which impeded the traffic, partly to the somewhat low state of the market for wheat, and partly to an unfavorable outturn. The low prices which ruled for this grain apparently tended to check the exports: 6,49,600 maunds of the total exports were conveyed by the Great Indian Peninsula Railway to Bombay and other stations west of Berar. Wheat is not imported to supplement the food-supply of the province. It is altogether an article of export trade. It is cultivated on the rich black soil of the Purna Valley, and on the loam that is found above the Southern Ghats.

.

Mr. O'Connor, Assistant Secretary to the Government of India, Financial Department, in reviewing the sea-borne trade returns for 1883-84, has noticed the immense increase in the export trade of wheat during the years 1881-82 to 1883-84. He anticipated that there would be a decline in the trade of the current year, and this prediction has been fully verified. "In the review for 1882-83, it was observed that the exports for the first three months of the year 1883-84 were about half of the whole exports of the previous year, but a doubt was expressed whether the trade would continue for the rest of the year on the same scale. The doubt was verified. If trade had continued on the same scale the exports would have been nearer 30 than 21 million cwt. Exports fell off sensibly after the first half of the year, and though by the end of the year they were 48 per cent in excess of those of 1882-83, they exceeded those of 1881-82 by only 5½ per cent—an increase which would not have been much for one year's trade and which was a small one for two years' trade. During the current year there has been a further decrease in the quantity exported, which for the first four months of the year amounts to only 5,903,916 cwt., a quantity which would represent, at the end of the year if trade continues on the same scale, not more than 17,700,000. But it is probable that before the end of the year, there will be a further material decline in the trade. The decrease indeed would already have been more marked had it not been that merchants had made large forward contracts both for tonnage and for delivery of wheat in the European markets. It has been more than once pointed out in these reviews that the trade in Indian wheat must be one of a very uncertain and fluctuating character. Its continuance on a very large scale depends on the concurrence of a number of circumstances: (1) abundant crops in India, (2) crops below the average in the United States and in Europe, (3) low rates of freight, (4) low rates of exchange. When all these exist together, the supply of Indian wheat which will be put on the consuming markets will astonish—as they have astonished—those who are but imperfectly acquainted with the capacity of India for the production of this grain. When one or other of them fails, the margin of profit, which is so slender at the best that exporters must work on a very extensive scale to obtain appreciable returns, shrinks in such a degree that the export will be carried on either to fulfil engagements already entered into, or as an unavoidable alternative to paying for imports in money. This year the second of the factors which must be present to make the wheat trade profitable has been absent.

.

"The harvests have been abundant in the United States and in Europe, stocks in hand are large, and the supplies in existence or in prospect are so considerable that the price of wheat in England has fallen to as low a point as has been known for a hundred years. Prices have not similarly fallen in India, and though it has been stated in a very positive way that India

can produce wheat at a much lower cost than the United States—an assertion to which I ventured, for reasons given, to demur altogether—the fact remains that India, in present circumstances, cannot afford to sell her wheat with profit for the price offering in London of 37s. a quarter and even less. In the first week of 1884 the average was 39s. a quarter, and by the end of February it had gone steadily down to 36s. 11d. Then there was a rise to 38s. 1d. by the end of March, and the average for the three months was 37s. 9d. In April it was 37s. 2d. and in May 38s. 2d. The price fell to 37s. in June, and the average for the three months was only 37s. 6d. a quarter. Since then prices have actually fallen as low as 34s. a quarter. Now, to leave a profit at all, Indian wheat must sell for 39s. or 40s. a quarter when prices in India and freights are both low. Everything at present points to the continuance of low prices for another year at least. The crops of the United States are the largest they have ever had, exceeding the average crop of the last five years by 60 million bushels according to careful estimates. The English harvest has been abundant, and the area under wheat was larger than in 1883. The production of all European countries, Russia, France, Italy, Southern Europe generally, and of the Australian Colonies, has been above the average. There is not therefore a bright prospect, as far as can be seen at present, for Indian wheat for the next twelve months, for it is not unlikely that prices may touch even a lower level than that already reached. To make the trade profitable, even possible, in these circumstances, it is essential that the charges, which weigh on Indian wheat between the time when it leaves the cultivator's hands and its arrival in the stores of the European millers, should be lessened. Lower cost of transport in India, lower rates of ocean-freight, reduction and elimination of unnecessary handling at railway stations and ports of shipment, the substitution of expeditious methods of loading and unloading for the clumsy and primitive methods now obtaining, more care in cleaning and classing the grain, are indispensable."

In connection with Mr. O'Connor's anticipations as to the decline of the foreign export trade of India in wheat, the following extracts from the *Pioneer* of the 3rd instant will be found interesting:—"The Indian wheat-grower may derive some consolation from the knowledge that if the American farmer has this year prevented the export of wheat from India, he has ruined himself in the process. Nothing is clearer than that wheat cannot be grown at a profit in the United States if the selling price is less than 33s. the quarter in the London market. With the present rates for wheat in Europe, the American farmer is simply ruined, and the American papers have shown conclusively that the western farmers are getting less for their wheat at the place of production than it had cost them to grow." *** "Another year of equally low prices would shut up thousands of farms in the far west, and already it is reported that the area under wheat this year in the States is 15 per cent less than in 1883-84. The American farmer is obliged to force his wheat on the European market, as he must convert his produce into cash, and there is comparatively no internal demand in his own country for it." *** "The Indian producer grows a variety of crops, and can sell the most profitable produce and store the rest. When wheat prices fall, he buries his wheat, and takes his sugar or his barley to market. Again, there is a great internal demand for wheat in India, and this is capable of great expansion whenever wheat is cheap. Thousands of persons in every district will eat wheat in preference to barley or bajra whenever it falls below 20 seers the rupee. As it rises above this rate, the internal consumption contracts." *** "The producer is getting lower prices than he probably expected, but he is not being ruined like his American rival, and he is getting a better price at the place of production for his grain than the latter. If Indian wheat prices were regulated as American wheat prices are, solely by the English market, and if Indian wheat had to be sent to Europe for sale at any price, we should then witness ruinously low prices in the up-country markets."

SOME information will now be given as to the price that will probably suffice to take a quarter of wheat from India to London. Mr. W. C. Bennett, when Director of Agriculture and Commerce, North-Western Provinces and Oudh, last July,

stated that the prime cost of raising a quarter of wheat in the North-Western Provinces and Oudh was about Rs. 9-8-0 or 15s. 10d., and of putting it into the Cawnpore market, Rs. 12 or 20s. He calculated that the railway freight of a quarter of wheat from Delhi to Bombay would be 6s. 6d. and from Fyzabad to Calcutta 5s. 2d. He took the freight by sea as 35s. a ton or 7s. 9d. a quarter from Calcutta and 30s. a ton or 6s. 8d. per quarter from Bombay. The price of exporting a quarter of wheat from these places to London would therefore be—

	From Delhi.	From Fyzabad.
Prime cost at market	... 20 0	20 0
Railway freight	... 6 6	5 2
Shipping do.	... 6 8	7 9
TOTAL	33 2	32 11

The average price of wheat in the English market was put down by Mr. Bennett at 40s. per quarter. According to these figures there would be left for incidental charges and profit 6s. 10d. for Delhi and 7s. 1d. for Fyzabad.

The following were the approximate cost price and transit charges of exporting wheat from Lahore to London via Kurrachee:—

	Per quarter.
Average price at Lahore	... 17 0
Railway charges to Kurrachee	... 7 5
Ocean freight at 35s. per ton	... 7 9
TOTAL	32 2

The price of exporting a quarter of wheat from America to London appears to have been as follows in 1882-83:—

	s. d.
Market price at Chicago	... 32 11
Railway charges to New York	... 6 2
Ocean freight to London	... 2 4
TOTAL	41 5

The lowest market prices in London then being 46s. per quarter for American wheat, 4s. 7d. were left for incidental charges and profit. Prices have fallen off since then, the latest and highest quotations being 37s. for American and 35s. for Indian wheat. The prospects of the wheat trade appear to be somewhat gloomy at present, but lately prices have shown a tendency to rise in the London market. Two statements are given, showing—(1) the wholesale prices of wheat per maund in April 1883 at the principal marts; (2) cost per ton by rail from Cawnpore and other places to Calcutta, Bombay, and Kurrachee. More recent information will shortly be given regarding the wheat movements in India, and the price it will take to send a quarter of wheat from the principal marts to London through the ports of Kurrachee, Bombay, and Calcutta.

INDIAN and China tea-growers had better look to their laurels. The Russian Government, which have been experimenting for some time past in the cultivation of tea, are once more putting forth all their energy to develop the tea plant in Central Asia. They have decided on laying out a plantation at Soukhum Kale, and import a ship-load of Chinese coolies to work it. Here they have followed in the footsteps of the British Consul at Tiflis who, not very long ago, grew a quantity of tea, and during the course of last summer, a German, who tried an experiment with a number of shrubs imported from China, succeeded to some extent. These, however, have been one and all tentative measures, and give one result in establishing the fact that tea can be cultivated in the Caucasus; but the important problem yet remains undetermined, whether it can be grown on such a large scale as will enable it to compete successfully with the article which is produced in India and China. As matters at present stand, all the tea consumed in Russia has to be imported, that is, 72,000,000 lbs. have to be purchased at a cost of £8,000,000. Half of this quantity conveyed to Russia overland across Siberia, and the other half borne by water to Odessa in the Black Sea and Kronstadt in the Baltic. If the experiment to be tried at Soukhum Kale is a success the foreign article will be at a discount, since Soukhum Kale is only a couple days' run from Odessa. But there is another and an important factor in a consideration

question; labour is at a premium in the Caucasus, and the moist climate of the country would materially interfere with emigration on a large scale. In this respect, the Indian and China coolie have the advantage, and besides, there not being much capital in the country for the development of the industry the assistance of foreign capitalists must needs be called in, and here the difficulty begins. Be that as it may, we have no doubt Indian tea-growers will watch with some interest the operations of the Russian Government in this direction.

.

CANADA is to have a Department of Agriculture. The Select Committee on Agriculture appointed by the Dominion Parliament, has just presented its report, which recommends that the Government should take into consideration the advisability of establishing a Bureau of Agriculture, and an experimental farm in connexion therewith; that this Bureau be formed in connexion with, and under the supervision of, the present Department of Agriculture; that the objects aimed at in the establishment of such bureau and farm be as follows:—1. To conduct such experiments in the introduction and culture of new varieties of seeds, plants, trees, &c., as will most efficiently aid in the advancement of Canadian agriculture, to institute experiments with regard to the comparative value of fertilisers, the proper testing of seeds as to vitality and purity, and the healthy preservation and productive condition of plants and animals. 2. To make careful investigation into the origin, distribution, and the habits of insects, injurious and beneficial, and the contagious and other diseases to which animals and plants are subject, in order to arrive at the best method of destroying and counteracting them. 3. To study the quality of the various breeds of cattle and other domestic animals, with the view of reporting on the best means of improving them, of protecting them from parasites and epidemic diseases, of feeding them for the market, and on the treatment of milch cattle. 4. To initiate and carry out a convenient and comprehensive system of gathering the latest and most useful information, statistical and otherwise. 5. To publish and send to the press and the various agricultural and horticultural societies of the Dominion, at different periods of the year, bulletins giving the results of trials made on the experimental farms, and whatever other information the Bureau may consider useful, either in the prevention of the ravages of insects and contagious diseases, concerning improved methods of culture that have stood test, or for the special advancement of any line of agricultural pursuits.

.

The official memorandum upon Indian wheat quoted by us in a recent article upon the subject, estimates the total wheat crop of British India to be 135 million cwts., or about 7,000,000 tons, and the average yield a little more than nine bushels per acre, or 560 lbs., against 28 bushels per acre in England. According to the same memorandum, the total export of Indian wheat in 1883 was 22½ million cwts., and that export is supposed to have been made, without any appreciable effect in raising prices. And the writer infers that with a favorable rainy season following an average wheat crop so as to secure the autumn or *khureef* harvest, one-fifth of the Indian wheat harvest may be spared for export, without materially enhancing prices. Of the total quantity exported in the year 1883, nearly one-half, 11,243,497 cwt., went to the United Kingdom. For the last few years, the British Isles have been the great market for all surplus Indian wheat, that market until very recently having been monopolized by Russia and America. Before 1880, India held a very insignificant place amongst the great sources of supply. The following table shows the respective quantities of wheat imported into the British Isles from Russia, the United States, and India since the year 1879:—

	1879.	1880.	1881.	1882.	1883.
	Cwts.	Cwts.	Cwts.	Cwts.	Cwts.
Russia	7,975,144	8,880,108	4,612,895	9,571,021	18,293,558
United States	35,976,805	26,089,429	30,038,074	35,079,828	26,065,832
British India	357,256	3,347,342	7,308,842	8,477,470	11,243,497

From this table, it is evident that the import of Indian wheat has become a main factor in the English supply, and was steadily increasing in importance and in bulk. India was in fact underselling both Russia and America in the British wheat market from 1879 to 1884. Owing to a combination of causes

that we need not enter upon here, the wheat-growing area in England is steadily diminishing, and the dependence of the kingdom upon foreign corn increasing every year. In 1879, the total quantity of wheat imported into the British Isles was 59,388,140 cwts. against 64,080,444 in 1883. It is to the interest of India and England alike, that this want should be supplied as far as possible from India alone, on many grounds, and in our previous article upon this subject, we have shown with what little difficulty the gross outturn of the Indian harvest might be indefinitely increased. Less than six million tons were found sufficient last year for consumption in India, and if we could raise the harvest from 135 millions to 270 by improved farming, i.e., from 560 to 1,120 lbs. per acre, there would be a margin of 7½ million tons for export, or three times the entire quantity required to supplement the English harvest—that is, it would cover the total quantity of foreign wheat imported in England, to supply the deficit of home growth, three times over. The demand for Indian wheat is daily increasing in the British market, and the Indian Government should grasp the idea of supplying this demand. We have suggested a resort to nitre as a practical improvement of wheat cultivation, but no system can claim infallibility. That which succeeds in one place is found useless in another. The great thing is the steady and enlightened pursuit of a given end.

.

A VERMONT newspaper, the *Rutland Daily Herald*, is printed on paper made from sawdust, the product of Mr. POND's roller pulp machine, by which sawdust, shavings, chips, and pieces of wood can be made with great rapidity into a pulp of clean, fine fibre. This machine will also manipulate the stalks of cotton, sugarcane, wild hemp, &c., at the rate of from two to three tons of dry pulp per diem. The resulting pulp is far superior to any other form of wood pulp, because the fibre is preserved intact and the cellulose is left with it, giving it great strength, softness, and pliability. The tensile strength, per square inch of newspaper, which contains from 50 to 75 per cent of ground wood pulp, is from 8 lb. to 12 lb., and stands a test of 17 lb. to the square inch, showing that it is much stronger than paper made from one-third rags. As all kinds of paper can be made from this pulp without the addition of rags, cotton, or jute, it can be manufactured at a reduction of from 30 to 50 per cent of the present cost. The unbleached pulp is also useful for wrapping paper, and is equal in colour and strength to the best manilla. The woods most adapted to the process are the soft woods, such as spruce, fir, pine, poplar, and hemlock, the latter making the strongest fibre, being quite equal to jute in strength. Besides the manufacture of paper, the pulp can also be utilized for wood ware, such as pails, barrels, and mouldings. Our Indian mills might take note we think of this new practice. The *renaissance* in Europe was largely attributable to the discovery of 'how to make paper,' and the cheapening of paper has been one of the foremost agencies in the progress of the 19th century.

.

A CORRESPONDENT writing to the *Times* says:—"The peasant who lives on his own land, drinks the milk from his own cow, eats the eggs from his own poultry, and pays for his bread, meat, clothes, and other charges with the surplus produce of his own labour and holding, is the pattern proprietor of the day. This picture of rural life is most attractive, and the only question is, can it be realized on ordinary commercial principles? It is assumed by the platform speakers who go forth from the large towns that the great landowners, aided by the land laws, have smothered the growth of such a proprietary class. Far from it, they desire to see such communities flourishing around them; but hitherto the progress and customs of agriculture in England have naturally led to a different result. Sir J. Caird has proved irrefutably that the small proprietor in this country fails on economical principles, for he produces a less outcome per acre than the large farmer. Still, that is no reason why such a class should not subsist, on the principle of 'the greater happiness to the greater number,' provided that the system be self-supporting. Now is the time for founding such settlements. But Messrs. Chamberlain and Collings are not justified in trying the experiment as they propose, by advances at the cost of the British tax-payer, with no security which can be realized if it fails. Large tracts of cultivated land, with all the improvements of buildings, enclosures, drainage, &c., which the money of the owners has added to

them, can now be easily obtained at a less price than has been known during this century, and Lord Cairns's Act has freed settled estates for the purposes of sale. Capital, the root of every enterprise, must be advanced. Let these capitalists form a company, call it the Liberal Land Loan, or Peasant Proprietary Company, or any other characteristic and attractive name, purchase extensive districts, sub-divide and allot them in suitable plots, and sell them to the would-be cultivators on payment of part of the purchase-money, with the remainder on mortgage. In all these schemes the plot appears to rank as an indivisible unit, whereas the death or failure of the proprietor necessarily tends to sale or sub-division, unless it be counteracted by a settlement on the footing of primogeniture, or some other exploded device. If it be desired to introduce an element of philanthropy into the undertaking, the promoters might, out of their own pockets, pay the cost of obtaining an indefeasible title under Lord Westbury's Act, which would legalize any sub-division or transfer of the plots by a simple entry in the register, and they might at the same time limit themselves to a rate of 5 per cent interest after the manner of the Artizans' Dwellings and other like companies.

.

"Why then, do advanced Liberals call for State aid, which is the exact equivalent of the bounty granted by the Governments of France and Germany to the native growers of beet-root sugar? Surely this is a doctrine which must be abhorrent to the President of the Board of Trade. I may add that, as Mr. Chamberlain is apparently anxious to obtain some knowledge on the subject of his pet project, he might usefully inquire into the working and fate of a peasant colony which his prototype, Mr. Fergus O'Connor, the Chartist, established within living memory. The French peasant is invariably quoted as the standard example for imitation. I have had an opportunity of watching his condition during my residence in a department where many cows were kept. There his house was bare, with an earthen floor, without any conveniences, save well-made closed bedsteads in the same room, and a good *armoire*. The cows were kept in sheds tied to stakes without crib or manger, on an earthen floor, without litter; armfuls of green clover in summer and hay in winter were thrown on the dirty ground before them for their food: still, the women made most excellent butter in consequence of the labour and care bestowed in pressing out the buttermilk. The soil was a rich sandy loam, and the climate superior to that of England, but the cultivation was very primitive, and the land so foul that the cattle were turned in to feed down the weeds after harvest; the best grown for the cows was almost entirely leaf with very little tuber, and the total produce per acre of all crops much below the average of arable in England. The staple food of the people was black bread made from buckwheat. No English labourer would bring himself down to the hard life and dirty home of the French peasant proprietor. The only member of this class who appeared to do well was the artisan who cultivated his plot when not at work at his trade.

.

"ALL these social problems cannot be solved by theory alone, but must be tested by facts. I will give the counterpart of rural life which lies under my eyes in England. It is said that the English peasant cannot rise from the ranks. There are now residing in a parish of some 1,200 acres close to my home the best grass farmer of the district, formerly, I believe, a carter, who married the dairymaid; he now rents a farm of nearly 200 acres and his two sons occupy similar holdings in adjoining villages; another, renting farmer and dealer, worked when a lad, under the gardener in the squire's garden; a third, very recently a farm labourer, now rents a small dairy farm; a fourth, who started in life with £50 in his pocket, became a renting farmer, and has now retired to a house of his own, and is succeeded in the farm by his son in this same village. I could cite many other instances of success in the neighbourhood, but none from the class who have aped the habits of the gentry, whose daughters play the piano, and contemptuously decline, as they phrase it, "to marry a cheese or a butter tub." It may be asked why more of these renting farmers, many of whom are also small proprietors, do not rise on their own property. They have found it hitherto more profitable either to sell or let their

land and invest their capital in farming business; hence the general tendency has been for the land to concentrate in the ownership of capitalists rather than to remain in the possession of the small proprietors in those districts where they previously existed. This accumulation of land in the hands of the few is the direct consequence of economical principles and trade instincts rather than of social change, and is predominant in Great Britain. Frenchmen and Irishmen move on different social lines. The political farmer may cultivate proprietary exotics with some hope of success on his own private forcing grounds; but I ask whether it be possible to cut up the land, and alter the habits, customs, and occupations of the great bulk of the rural population by legislative measures, however arbitrary, even though baited with the flesh hooks of confiscation."

.

The following communication from Mr. A. K. Connell to a home contemporary will be read with great interest:—"With your permission, I should like to supplement the figures, recently given in the *Times*, as regards the American and Canadian wheat trade, by those of the Indian wheat trade. The Indian Government has issued various interesting reports as regards the cost of growing wheat in India, but that most recently drawn up by Mr. W. C. Bennett, Director of the Agricultural Department of the North-West Provinces and Oude, is of the greatest importance. The provinces contain the best wheat land in the whole of India and the area under wheat has increased more rapidly in that part of India than in any other. The statistics given are generally applicable to the rest of India, except, perhaps, the Central Provinces, where the farms are larger, rents are lower, and the pasturage is more extensive. According to Mr. Bennett, the cost of raising a bushel of wheat is about 1 rupee 3 annas, while the selling price, at a time when exports are large, is about 1 rupee 8 annas. Rather more than one-third of the cost is paid in cash, the rest is paid in kind to the labourers, or goes to support the cultivator and his family. The average yield on the dry land is 12 bushels, and on irrigated land 22 bushels of grain and 1 ton of straw per acre, the average size of farm being five acres, but sometimes the out-turn is as high as 33 bushels an acre. The conclusion to which Mr. Bennett comes, writing last July, when prices were fairly high in the foreign market, is that, when the profits of the corn dealer and the expense of bringing wheat to market are taken into account, it is not probable that the cultivator (at 40lb. for the rupee) recovers more than the value of his labour and interest on his capital expenditure on cattle and implements. If this estimate is correct as regards the most fertile districts of India, it is not probable that a higher profit is realized elsewhere, except where there is a sparse population on a good soil, and the surplus left, after feeding the cultivators and labourers, is much greater than in Northern India.

.

"THE next point is the cost of transport from up-country districts to the sea-board. The distance by rail varies from about 900 to 300 miles, and the charge for equal distances varies on the different lines. From Delhi to Bombay (890 miles) the charge last summer was 6s. 6d. a quarter of wheat, Fyzabad to Calcutta (598 miles) 5s. 2d. a quarter, whereas the Great Indian Peninsula line charged not long since, for a distance of 616 miles, 6s. 8d. per quarter. From Lahore to Kurrachee the charge was in 1883 about the same as from Delhi to Bombay, but, since the reduction of the charges on the Rajpootana line, it is rather more. The lowest charges in India are on the East Indian line, and were last July, according to Mr. Bennett, one-eighth of a pie (one-eighth of a penny) per maund per mile, compared with one-seventh of a pie per maund (80lb.) on American wheat carrying lines. Freight from India to England were last summer, after the Indian wheat harvests, about 7s. 9d. per quarter from Calcutta, and 6s. 8d. from Bombay, and rather higher from Kurrachee. Putting the incidental charges at three to four shillings a quarter at the least, it is clear that wheat cannot be laid down in London at the present price with any profit to the Indian grower, and if the wheat trade continues without the price rising it must be supposed that the profits, if any, go to the

Indian middleman, owing to the difference between the buying and selling price, or to the Indian Government in taxes and rent.

"How very small the margin of profit must be even to the middleman, when he buys at the cheap rate current at harvest time, is clear from the fact that during the last year the Indian wheat trade has suddenly shrunk by 17½ per cent at Bombay and Kurrachee, while at Calcutta it has not been one-third of what it was in 1883. And it must be remembered, as I have before pointed out in the columns of the *Times*, that, owing to the system of State loans and guarantees for railways, there is a serious set-off against any profits to the Indian grower by reason of the interest charges which he has had to pay in the past, to the amount of many millions, for all the wheat lines, and which he has still to pay for four of them—viz., the Oude and Rohilkund, the Scinde, Punjab, and Delhi, the Indus Valley, and the Northern Punjab. None of these railways pay their interest charges, and the deficit on the Indus Valley and Scinde and Delhi lines alone amounts to about £400,000. As on those two lines wheat forms one-third of the goods traffic, and, since they have been open, the price of wheat has risen only about 15 per cent, the gain to the agriculturist on the price of wheat has to be set against the loss in the bounty paid out of taxation to the railways. A declared freetrader like Lord Ripon appears to ignore this fact in his speech. There is reason to doubt whether the net result is in the grower's favour, even when prices are high; but if they fall, the net loss by reason of the grant-in-aid to the railways is undeniable though it may be borne only in part by the Punjabi. These railways were, of course, built with a special eye to military purposes, and so far must not be judged from a commercial point of view, but regarded from the standpoint of the economist, they ought to make us hesitate before asking the Indian Government, as Mr. George Potter does, to build more wheat-carrying lines, which may bring a heavy burden on the Indian taxpayer, and artificially stimulate the competition of India and America for the foreign wheat market. For India, as a whole, it is better to store its surplus corn crops, or distribute them in India, than to be encouraged by bounties to export them, and for the purpose of distribution, metalled cross-country roads are wanted sadly in most districts. Does not the teaching of Adam Smith (*Rk. i.*, chapter xi), on the evil effects of bounties "in hindering the abundance of one year from compensating the scarcity of another," apply with equal force to grants-in-aid to the carrying trade of a country? Is it fair to the Indian townsman to raise prices, is it fair to the English farmer to lower them, by this disguised system of protection? This is the question which ought to be discussed."

LAND-REVENUE IN BURMAH.

An important correspondence has lately passed between the Government of India and the Chief Commissioner of British Burmah, on the subject of postponing the land revenue instalments in that province. From the papers published, it appears that rice is reaped in the Pegu and Salween deltas one to three weeks later than it is in the upper districts, Henzada and Prome, or in the Akyab district. In those tracts where the reaping and harvesting is latest, the cutting of rice is finished by the 20th of January, and in another three or four weeks, they are all sent to the rice mills at the sea-ports. Under the rules in force at present, the 15th of February is the fixed date on which the land revenue falls due. Unlike Bengal, the entire amount of revenue is payable in one instalment except a very small portion called the 'kaing' that is, the Government demand on spring cultivation, which falls due on the 1st of April. Looking at the time when the harvest is gathered, and that on which the instalment falls due, it is quite apparent that the cultivators have little time to dispose of to advantage what has been reaped only a few days previously. The Settlement officers, taking these facts into consideration recommend that the 15th March, instead of the 15th February, be fixed as the date on which the land revenue shall be due. We might as well premise here that in former years, from one-third to half the land revenue was not actually collected till the middle of March, and there was no rigid law in regard to collection. Last year, however, special effort was made to get in the

revenue quickly, and the arrears due on the 30th day of March was from 15 to 20 lakhs less than in former years. About three years ago, the opinion of Burmah revenue officers was taken, which showed that there was no need for changing the date for payment of land revenue on rice land, and the Chief Commissioner himself sees no reason for change, although he cannot but admit that it would be a positive gain to the majority of rice cultivators. Now, rice occupies nine-tenths of all the cultivated land in the province. The postponement will enable the landholders who cultivate with their own appliances and means, to keep their paddy out of the market during the early portion of the season when, as a matter of course, prices are low. They can thus abide their own time, and dictate their own terms a little later on. But what effect will this measure have upon the interests of mill-owners, who expect paddy to come pouring in, in large quantities, by the 25th of February. It will certainly interfere with any forward arrangements they might have entered into in the matter of exporting rice to other countries. But, on the other hand, there are many landholders who have to hire both labour and capital, and the demand for money to pay for these is heavier than the demand for money to pay the revenue, and they would naturally dispose of their stock at the current price, instead of waiting for a rise in the market, and consequently, the postponement of the revenue demand till the 15th of March might not cause any very great diminution of the supply of paddy to the rice mills during February and March. Should, however, the owners of these mills have chartered freight forward for the beginning of the season, a year's notice is sufficient to prepare them for the event, if it is decided upon. The postponement of the date for beginning collections from the 15th February to the 15th March, will mean that from 30 to 50 lakhs of Burmah land revenue will be collected after the last day in March instead of before that date. The Chief Commissioner says :—

The financial ways and means of the Empire for that official year will be affected to that amount, and the financial ways and means of the province will be affected to one-third of that amount. The Chief Commissioner is not aware whether the Government of India can afford to lose this sum in any one year. Apparently, the loss could not be accepted in the current year, as the budget estimates were framed on the expectation that the whole revenue of the year would be realized. But if the Government of India were pleased to frame the estimates for 1885-86 so as to admit of a loss of from 30 to 50 lakhs (say 40 lakhs as a mean) of Burmah land revenue in that year, then the Chief Commissioner advises that the postponement of the land revenue date be carried out. He believes that such postponement would be a benefit and convenience to the people.

The Government of India were at first disposed to limit the postponement of the date of payment to the districts or parts of districts where the greatest inconvenience is caused by the maintenance of the existing date; but as the season was then so far advanced that any order for postponing land revenue instalments would not reach revenue officers in circles until the arrangements for collection were in actual progress, the orders were countermanded and the introduction of the scheme for the postponement of the dates of payment of 15 lakhs of land revenue in certain districts was deferred until the year 1886-87.

THE COAL QUESTION.

HAD proper enterprise but been shown in extending the Railway system upon a well-considered general plan, we should by this time have had such a network of lines as would have not only completed the military system, but have equalised the agricultural produce of the country, by rendering the surplus crops of one district available to fill up the deficient crop in another, which can only be done when the rate, or cost of transport, will admit of its being sold at a very small increase upon the average price of local produce. At present, the most abundant crop of rice or any other food grain, if it be grown twenty miles off a line of railway or water carriage, is practically useless as an equaliser for a deficiency elsewhere, as the expense of cartage to and from the place of debarkation increases its value to an almost prohibitive price for the mass of the ryots and other consumers who, having lost a large portion of their own crops, are the less able to pay the exorbitant price demanded for its imported substitute.

Railway companies, as a rule, are very willing to meet the public half-way in any question of reduction of freight, but complain of the high prices they are obliged to pay for coal. Of course imported coal cannot be sold under a certain price, but what we complain

of is, that the indigenous resources of the country are utterly neglected, although the attention of the Government has been called to the fact, not only in these columns, but in the columns of every leading paper in the empire. Take, for instance, the millions of tons of the best steam coal in India which are lying *in situ* in the state of Rewah, peacefully reposing, undisturbed by pick or shovel, whilst the Railway Companies are starved for want of that very fuel, which is to them so near, and yet so far. We know that a railway connecting the mines with the East Indian Railway at Kutni, forty miles distant, is being made, and we hear it is being pushed on, in accordance with the Secretary of State's order, dated August 1884; but how do we stand with regard to the coal mines? Why are they not being utilized? A Colonel of Engineers, who has made the supply and demand of Indian coal an official study, visited them last October in company with the gentleman in charge of them. He was much pleased with what he saw, and recognised at once the enormous value, both geographically and economically, of the Rewah coal fields which, if properly worked, will raise 300,000 tons of coal annually for the supply of the Central Indian and Western India railway systems, which coal can be sold at the pit's mouth, or at Kutni, at from 3 to 3½ rupees per ton against 13 to 15 rupees per ton, which is the present price of Raneegeunge, or imported coal at Kutni. The Colonel recommended in his report that a scheme should be drawn up without delay for their efficient working, and the necessary steps taken for their fullest development with as little delay as possible. Unfortunately for the carrying out of the scheme, that officer went on leave, and has not since returned. The Director of the Mines was called to Calcutta at the end of last December, and in obedience to orders, submitted an ably drawn working scheme which had been carefully prepared by professional men, to whom coal-mining and all belonging to it was second nature; it had been framed upon the intention of giving full effect to the importance and capabilities of the mines, and raising every ton of coal that could find a ready sale. This scheme had to run the gauntlet of five Colonels of Royal Engineers and a departmental member of Council, before it could be adopted. Four of the R. Es. assented and approved of the scheme, but the fifth negatived the whole plan, and the member of Council following suit, nothing was done beyond appointing the heads of the staff. No arrangements for machinery are being made, and no labor department is being organized; and as these are the essentials of a working colliery, it goes without saying that the mines are not being worked, and never can be worked under the half-developed system at present enforced by those who are answerable for the arrangements.

The fatal error in the Government scheme is ignoring the necessity for a special labor department. There is no surplus of mining labor in India, because underground work is generally disliked by the Indian laboring class who never take to it except for a *quid pro quo*, considerably above the daily wages earned, and the most successful and effective one has been found to be the settling himself and his family comfortably, with a small plot of garden ground, in villages belonging to the colliery, and protecting them from the excesses of themselves and their evil advisers. Colliery managers never train more hands than they require, or house and settle miners for whom they have no work, *e.g.*, there is no available mining labor which can be hired for any new undertaking; each and every industry requiring skilled labor must train it for itself. Underground coal-cutting is a speciality often requiring both firmness and strictness on the part of the managers. Orders have to be given and obeyed which a half-trained miner may think harsh, unnecessary, or both, and in a moment of unreasoning anger he will make up his mind to run away, and he does run away unless you have a little anchor on him, and the simplest and least irksome is a proprietary right over his house and belongings. It may be taken as a mining axiom that the miner over whom you have no domestic control is not worth the trouble of training, as he will run away from an imaginary grievance quite as soon as from a real one, and, like a wayward child, skulk in the jungle, without having the manliness to come back.

These little technicalities Members of Council and Royal Engineers are not expected to know; such knowledge comes not intuitively, but is the result of years of patient industry and quiet observation; but it is much to be regretted that when information so laboriously gained is placed at the disposal of heads of departments, it is not accepted in the same spirit as that in which it is offered. Government commercial transactions are generally very costly failures, because there are no responsible heads. Colonels of Engineers, and such like amateurs, never spend money at the right time; they spend three times as much money in the long run as any professional or private company would have done, but two-thirds of it is the

cost of rectifying their own early mistakes, which they have blindly or obstinately drifted into by pursuing a course that must lead to ruin; but by the time it arrives, the authors of it have left that work, and perhaps the country, and their successors point with pride to the failure of their predecessor, proclaiming their own innocence, and then begins another reign of irresponsibility, and so on *ad infinitum*. The frigid policy now in favor regarding the Rewah coal fields, the hanging back from raising coal in anything like the requirements of the Railway Companies, or the capabilities of the coal deposits, is due to two causes. One is to save the Government collieries of Warrora and Mohpani from certain loss, if not extinction, which can only be done by keeping Rewah coal at the bottom of the pit; and the other is to help the small Bengal Coal proprietors to keep their shares at a notitious value, by making it a case of Hobson's choice. Give the Railway Companies a choice between Rewah and Bengal, and Bengal coal shares will fall somewhat in value, and this is a good and valid reason for shareholders to try and keep Rewah coal out of the market; but it is not a sufficient reason for the Government to aid them at the expense of the Railway Companies, who are now spending lakhs of rupees annually on coal account which is entirely unnecessary, and would be better employed in reducing freights, equalising the agricultural produce of the country, and feeding the hungry in the less favored districts, where the food crops have partially failed.

Miscellaneous Items.

THERE has been another heavy fall of snow on the Murree hills. The road to the Gullies is so blocked up as to be indistinguishable.

THE Neriad Agricultural Exhibition was opened lately by the President, Mr. Spry, in the presence of a large assemblage of people.

THE French barque *d'Artaquin*, Captain Palvadan, anchored in the Pondicherry roads on Friday last, having on board 150 returned contract coolies shipped from St. Denis, Reunion.

MR. J. C. McDONNELL, Deputy Conservator of Forests, of the 2nd grade in the Punjab, has been appointed to officiate in the first grade of Deputy Conservators, with effect from the 31st January 1885, or until further orders.

THE right to sell opium and intoxicating drugs within Madras municipal limits, during the year 1885-86, was put up by the Collector to auction, at the Custom House, last week, and was bought by a single bidder, a Manomedan, named Shalam Khan, for Rs. 17,000. Last year the sale produced Rs. 20,020.

WE understand that a company is being started in Poona for the purpose of manufacturing manure by a chemical process, recently patented by Professor Samuel Cooke, of the College of Science. We have every reason to believe that this new manufacture will prove of great benefit to the class for whom it is intended. New industries are just what are wanted, to relieve the depression of the present time.

THE Mixed Committee, composed of the British and Portuguese Commissioners sitting at Goa, have concluded their labours regarding the salt question. The result has not yet transpired, but with respect to the increase of the alkali tax, the British side has carried its point. The tax will be increased to Rs. 4 at Goa, and to Rs. 5 at Damau and Diu. The Committee are proceeding to Goa and Diu to settle the question of salt.

MR. JAMES MORRIS, architect of Humnunn-street, Bombay, has filed a patent for "fire-proof and sound-proof flooring suitable for business premises and public buildings, dwelling houses, open terraces, and native chawls." Mr. Samuel Cook, Professor of Chemistry and Geology, at the Poona College of Science, has registered a patent for the manufacture of chemical manures from materials locally obtainable in the raw condition.

THE surplus irrigation last year amounted to Rs. 25,73,133, after deducting the charges for maintenance and interest on outlay for productive public works. This is an advance of nearly 7½ lakhs on the surplus for 1882-83, resulting from a large increase in the gross income, and only a small additional expenditure. The area irrigated was 323,490 acres more than in the previous year. The season was particularly favorable to the development of irrigation owing to a scanty rainfall.

FROM the accounts of the trade and navigation of British India for the first ten months of the current financial year, as compared with those for the corresponding period of the last year, we see that the value of merchandise imported was Rs. 46,71,61,433, as against Rs. 46,37,95,594, and that of merchandise exported Rs. 66,73,77,910, as against Rs. 71,77,87,939. The value of treasure imported was Rs. 11,70,32,897, as against Rs. 9,04,30,446, and the value of treasure exported was Rs. 1,07,15,028, as against Rs. 87,38,864. The gross amount of import duty collected was Rs. 1,95,18,768, as against Rs. 1,84,03,559, whilst the amount of export duty collected was Rs. 35,40,234, as against Rs. 47,15,576.

The scarcity of water at Bangalore has now become so great that the General commanding has issued an order, warning all persons to exercise the strictest economy in their use of it, and fixing the maximum quantity to be allowed each barrack per diem. Thus it appears that the Royal Horse Artillery at the Ussur Barracks are allowed 6,000 gallons a day, the Cavalry and Field Batteries at the Agrar Barracks 21,000 gallons, and the Infantry and Bakery 11,000 gallons. What the allowance will be reduced to before the rains begin, it is difficult to say.

The establishment of the Bombay Oil Manufacturing Company bids fair to meet the increasing demand for coconut and other oils which is felt in our midst by railway companies and cotton mills. Hitherto this demand was met by imports of oils from Cochin and the Malabar Coast. The new company has shown that it can supply oils of all kinds much more cheaply, and of a superior quality. The Company has already gained the confidence of many of the Bombay mill-owners. The oils have been tried by Messrs. Kemp and Co., Treacher and Co., and Deputy Surgeon-General Dymock, who have testified to their excellence. We wish Messrs. Jugmohandas and Shapurjee—the promoters of the new industry—every success. There is a vast scope for the Company in this new line of industry in Bombay.

OTHER devices having apparently failed, the New Zealand Government has been seeking to combat the rabbit plague by the importation of a large number of weasels and stoats from England. We read that a third consignment of 158 of these animals were recently despatched to the Colony from London. They were obtained chiefly in Lincolnshire, at an average cost of five shillings a head. Special arrangements had, of course, to be made for the transport of the novel freight to the Colony, and it seems that the weasels and stoats were confined during the voyage, in trunks, in zinc-lined boxes, and that a consignment of 2,430 pigeons was carried on board for their food. The New Zealand Government appears to be in great straits over the rabbit question. A year ago, it may be remembered, the colonists asked the aid of the Government of India in their difficulties, requesting a consignment of mongooses from this country. The mongooses were, we believe, in due course, sent, but have, seemingly, been as unsuccessful as were the gins and traps which had already proved unavailing.

Selections.

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The Ordinary General Meeting was held on Wednesday, the 26th February 1885.

W. H. CONSWELL, Esq., President, in the Chair.

COMMUNICATIONS.

From C. H. Vowell, Esq., C.S., Collector of Patna, applying for instructions for sowing Carolina Paddy—supplied.

Dr. E. Bonavia, Etawah, referring to Mr. S. H. Robinson's Prize Essay on the Sugar Date (published in Vol X of this Society's Journal), and the figures therein given of the production of sugar in Bengal, enquiring whether the output has decreased, and if statistics are available regarding the amount of Date Sugar manufactured. Dr. Bonavia was informed that as far as statistics are available, no decrease is shown in the production of Date Sugar; according to the Bengal Administration Report for 1883-84, the export of sugar rose 86 per cent in the year it reviews, "and would, it is said, have been still larger, but for the competition in the English market of Beet Sugar imported from Germany." There is no distinction made in the statistical returns of goods exported to foreign countries from Bengal, but the figures given of exports are:—*Drained sugar*, Maunds 3,06,057, and *Undrained sugar*, Maunds 88,601.

The only direct reference to the production of Date Sugar is in the Bengal report for 1882-83, where it remarks that its cultivation and manufacture are extensively carried on in the districts of Furruckpore, Bhagulpore and Jessore, in parts of Nuddea, the 24 Pargunnahs and Khoolna, and that in the Bhagulpore district the annual output of *goor* is estimated at maunds 1,15,000. In Jessore there were, it is stated, 24,122 acres under Date cultivation in 1882-83, and the output of coarse sugar was 10,056 tons, the value of sugar, refined and coarse for that district during the year was Rs. 27,72,599 for sugar (*cheener*), and Rs. 20,73,642 for coarse sugar (*goor*), or the considerable sum total of Rs. 48,46,241 for the one district.

From the Librarian, Public Library, Museum, and National Gallery, Victoria, forwarding Baron Von Mueller's *Eucalyptographia Decade X*, presented to the Society by the Hon'ble the Premier at the Baron's request, a vote of thanks was accorded for this valuable work.

From Major A. Talbot, Bilanir, Rajpootana, reporting the success of some of the Lawn grass seed imported from Australia. In reference to the *Tricholoma Rosea*, which was described as being specially suited to dry sandy localities, and the seed of which the Society procured from Natal last year, Major Talbot remarks:—"The *Tricholoma Rosea* has not done very well. Of some seed sown in sandy soil and not irrigated, none came up; of other seed sown also in sandy soil, but regularly irrigated, a few plants only came up. It appears to grow in small distinct clumps, and not to spread over the surface of the ground to any distance, but as these few plants have seeded themselves, possibly the grass may spread more this year. I doubt of its fulfilling the expectations formed of its utility for fodder, from its slow and uncertain growth in a soil supposed to be peculiarly well suited to it.

"The *Rosa Luxurians* has done better, and though from the poverty of the soil it is not luxuriant as it is said to be elsewhere, I have a number of healthy plants, they have suffered from the cold, but will soon start into growth again. These plants have been irrigated twice a week, with a larger supply of water they would probably be finer plants than they are; when well established they seem able to defy white ants, but while still young, many of them are eaten."

From the Dewan Lakshpat Ray, of Kashmir, forwarding a note on vine culture in Kashmir, which has been transferred to the Journal, and advising the despatch of a basket of grafts of Apples, Pears and Cherries. As the Society was unable to utilize them, having no stocks, the presentation was transferred to Dr. King for experiment at Darjeeling. The Dewan, when visiting Calcutta lately, called at the Society's office and expressed the interest he took in the improvement of Agriculture in Kashmir, and his readiness to experiment with any seeds or plants the Society might wish tried, or acclimated by culture there.

From Captain F. Pogson, forwarding for examination and report a rope made from the bark of the *Maul Dhun* creeper, which grows abundantly and to a considerable size in the forest. The rope is very strong and is used for tethering cattle, the leaves are used by the *Bunnias* and *Hawats* for packing purposes, and are large and tough. Captain Pogson goes on: "It appears to me, that under culture the young bark would be of considerable value for numerous purposes, including the manufacture of sacking and canvas, while the refuse would answer very well for paper." The plant has been identified as the *Bauhinia Vahlia*, well known for the strength of its fibrous bark, ropes constructed of which are used in suspension bridges by the natives. Captain Pogson has been asked to obtain some of the seed for the Society.

Captain Pogson promises some further information regarding a sorghum cultivated in Hurriana, which has been grown there for years by the Zemindars in place of sugarcane, it is called "Alapour Joar," and the fact of its being thus cultivated is in itself the best certificate of its usefulness.

INSECT PEST.

From R. Cornish, Esq., C.S., Officiating Collector of Midnapore, forwarding a packet of a plant infected with the larva of some insect, which is said to be injuriously affecting the crops; he enquires what they are and what remedy may be suggested. The specimens were forwarded to Mr. Wood-Mason, whose reply is given in full; as, by attending to his valuable suggestions, correspondents sending insects for identification or report would ensure their arriving in good order.

"From such a dried and bruised specimen as that which you submitted to me yesterday, it is not possible to ascertain the nature of the lesions, if any, from which the plants have suffered. I have carefully examined all the *debris*, and amongst the several species of insects which this contains, I have found the dried and shrivelled bodies of a species of plant-louse (*Aphis*) in considerable numbers. I have also found a few of the same species in the interstices of the pith. It is possible that the attacks of these insects may have caused the immitation of the seed capsules, which is to be observed in the specimen. But it is, to say the least, doubtful whether the condition of the plant is due to insect agency at all. References of this nature should be accompanied by a description of the nature of the disease or of the injuries from which the plants are suffering, and by spirit specimens, both of the supposed pests and of the injured leaves, or other parts of the plants."

ANNUAL FLOWER SHOW.

The Annual Flower Show was held on the 6th February, and was marred by the stormy unsettled weather we were then experiencing. The night before the Show, when all the plants were in position on the stages, and all arrangements were completed, a sudden and sharp storm blew down all the tents, with the exception of two corner ones and one of the shamianas kindly lent by H. H. the Lieutenant-Governor. A great deal of damage was done to several valuable plants, but, on the whole, considerably less than might have been expected after such a mishap. Probably Biboo S. P. Chatterjee was the greatest loser, one or two of his most valuable plants being irretrievably ruined. It was for some time probable that the Show would have to be postponed, but it was finally resolved to carry it through though it was with considerable difficulty that the tents were re-erected and the plants re-arranged before the Judges went round, and some minor details had to be neglected as the whole staff were engaged in repairing the damage caused by the storm, in the garden itself as well as in the Exhibition.

There was writing the names of the plants where they had been destroyed, preparing cards with names of Exhibitors, and some other less important matters, had to be passed over. By the time visitors were admitted most of the damage had been repaired, and had the afternoon been fine, the Show would have been as successful as any of the preceding ones. Notwithstanding the threatening weather, which finally turned to rain, before the afternoon was over, her Excellency the Countess of Dufferin accompanied by Lady Helen Blackwood and Sir James and Lady Ferguson, as well as H. H. the Lieutenant-Governor, Lady Rivers Thompson, and the Misses Thompson, visited the Show; owing to the unavoidable absence of the President, they were received by Messrs. G. L. Kemp, D. Cruickshank, H. J. Leitch and J. Martin, Vice-Presidents, and Dr. G. King, Raja Sutyamundo Ghosal, Bahadur, Mr. Piggott, and Baboo Pratapa Chandra Ghose, and conducted round the Exhibition.

H. H. the Maharaja of Cooh Behar kindly lent his band.

The collection of plants exhibited showed an improvement as to quality over preceding years. The collection of Begonias, Coleus, and Ferns were exceedingly fine, and there was as usual a good display of Crotons, and it is worthy of note that some of them had been grown under glass, which marks a step in amateur horticulture in Calcutta.

The Cut flower section had a smaller number of exhibitors than would have been the case, but for the rain and hail on the previous night; most of these shown were cut the evening before, and the Camellias and Roses were very fine for Bengal. A large number of *malis* exhibited vegetables, which were not especially good, and contrasted very unfavorably with the splendid collection exhibited by Mr. Maries, of the Durbhunga Raj Garden, who generously did not compete; Mr. W. Stalkart, of Goosery, too, sent some fine vegetables from his Garden at Goosery, the tomatoes were particularly fine, as also were the Potatoes exhibited by Mr. J. Stalkart, of Hope Town, Darjeeling; as these gentlemen did not compete, the thanks of the Society are the more due to them for their public spirit in exhibiting and sending their vegetables such great distances. Mr. Maries' having come from Durbhunga, and Mr. J. Stalkart's from Darjeeling. If these good examples were followed by other gentlemen in the Mofussil, a class might be made in which they might compete with each other. The fruit of the Pandanus appears to have attracted some attention, as it was not recognised by the majority of the visitors. It forms an article of diet in the Nicobars and elsewhere, the fruit being reduced to a powder; the process has been detailed in this Society's Journal.

The Royal Botanic Garden as usual contributed, as in previous years, a choice and interesting collection of plants for Exhibition only.

The Grant Silver Medal was awarded to S. P. Chatterjee, of the Victoria Nursery. The collection included some rare plants, and was arranged with much taste and skill, which reflected great credit on the exhibitor, when it is taken into consideration that the Shamiana in which the plants were placed, had in its fall caused considerable damage to several plants which had to be replaced within a very limited period of time.

In all Rs. 732 were awarded for prizes, according to the schedule. Some classes not having been filled, the extra sum at the disposal of the Judges was given for plants or vegetables not included in the list.

Out of the sum of Rs. 100 placed at the disposal of the Committee by the President, for plants either rare, well-grown, or not included in the Schedule, Rs. 85 was expended.

INTERCHANGE WITH COLONIES.

From C. S. Bailey, Esq., C.S., Officiating Under-Secretary to the Government of India, forwarding the following extract from the Principal Under-Secretary's Colonial Office, Sydney, letter to the Secretary to the Government of India:—"I have the honor to request that you will kindly convey to the Agricultural and Horticultural Society of India, the thanks of this Government for the seeds presented by them to the representatives of the Colony at the Calcutta Exhibition."

A case of fruit grafts has, at the suggestion of Mr. Stewart, the Emigration Agent for Fiji, been forwarded by the *Main*, which left on the 18th instant for that Colony, and an interchange, which has proved of interest in previous years, resumed.

RICHARD BLECHYNDEN, JUNIOR,
Deputy Secretary.

PEPPER VINE.

COLONEL E. B. SLADEN, Commissioner of Aracan, has very courteously placed at our disposal the following report from Captain C. A. Cresswell, Deputy Commissioner, Sandoway, on the results attending the experimental cultivation of the Pepper Vine, in the neighbourhood of the town of Sandoway. Before making any remarks on the cultivation of the pepper vine and its probable success, it would be as well perhaps, as this is the fourth year of the experiment, to give the actual position as regards number and size of plants as actually counted about the 14th February 1885, and which will be entered as 1884 and compared with those of 1883, counted in March 1884 and entered as 1883.

DODAUNG.

BLOCKS.	Under one Foot.		From one to two Feet.		Over two Feet.

181	78	80	229

A great part of the Dodaung cultivation is now, I find, not fitted for the pepper vine. The original acreage taken up was 105 acres. The decrease in the number of plants is due to the fact that in March 1884, over 400 plants were destroyed by fire in Block 2, and further from Blocks 1, 2, and 3. I have now thrown out about forty acres as ground upon which the vine is not likely to succeed. The ground will not be given up but will be simply left to take care of itself; if the young cuttings at present existing

struggle up, they can be looked after hereafter. The acreage, as at present looked after by the two gardeners in Dodaung, is 62 acres only, and in April and May I shall again inspect the whole of this ground, and finally decide what is worth keeping up.

Block (4) I intend to devote special attention to, as the ground is good and the trees are doing capitally. I have taken on to Block (4) at the cost of five rupees, an old sugar-cane plantation of over 3 acres, and there I have put down one hundred cuttings of the *Erythrina Indica*, most of which have struck, and will be ready for the young vines to be planted at their foot next June.

This is the method adopted on the Malabar coast, and is, I think, a far better plan than planting the trees in a jungle, where the ground is not of uniform quality, and the vines of course have to be spread over a large area.

By this method (the Malabar plan), about 225 trees can be planted to an acre, and after four years an average crop of one lb. a tree might be expected.

The yield in Sumatra is however very different; there an acre of first class vines will yield from 1,161 pounds of pepper.

In Malabar the average yield from 1,000 plants is only put down as 450 lbs. or less than 1 lb. a tree. From what is actually gathered from trees in Sandoway, I think I am justified in putting down 1 lb. for each tree.

Seven pounds is looked upon in Malabar as a very high yield for one tree. Seven pounds is sometimes realized from the old and uncared for trees round Sandoway.

The price at present here is Rs. 1-12-0 a viss. A valuable product in comparatively small bulk, and one which will bear the expenses of transport which paddy rarely does in the Sandoway District.

In Dodaung I expect from 50 to 100 trees to fruit next year, in February 1886. In Kyaung-daung from 200 to 250 in February 1886, or say a total in the two plantations of 300 trees and a produce of say 300 lbs. of pepper, and taking the produce of the year at 8 annas a pound, 150 rupees ought to be realized in March 1886.

The allotment was in—

1882-83	Rs. 500
1883-84	500
1884-85	300
1885-86	200 (proposed)

For 1885-86 I only propose to keep one gardener, and I propose to limit the expenditure to 200 rupees.

This would give the receipts as 150 rupees on an expenditure of 1,500, rupees or say roughly 10 per cent.

In 1886-87 a far larger yield might be looked for, and the gardens should be not only self-supporting, but should give a surplus over the expenditure for that year.

I do hope that the gardens will be kept up till April 1886, and then Government will be fairly able to form an opinion whether the experiment has been a practical success or not. Of course in an undertaking of this sort I had at first no practical experience.

My first idea was that deep shade was necessary, and that the soil was, comparatively speaking, a secondary consideration.

The first place I fixed upon was Dodaung. This had been frequently worked as *taungya*, and consequently large shady trees were only to be found here and there. This led to the work being scattered over a large area.

By the second and third year from the undergrowth being cleared away, &c., the trees had sprung up considerably, and more shade was obtained and more trees fit for planting. But still the vines only flourished in certain places, and that was in places where there was the best soil.

Given good soil, shade seems to be an unimportant factor. In Malabar alluvial soil is said to be the best. As I have already said, I think the Malabar method is likely to be the most successful.

Cuttings of *Erythrina Indica* (Pauil Kathet) are put down 14 feet apart in the dry weather, and by June next are ready for the pepper vine plants or cuttings. They are all planted in straight lines, and a plantation is easily watched and inspected. In four years the vines begin to fruit and last for 25 years in the case of cuttings; 40 in the case of seedlings.

One of each is usually planted at the foot of each tree. This method of cultivation is somewhat similar to that adopted by the people for the betel vine, so that they will be more likely to take it up.

There is no difficulty attached to the cultivation of the pepper vine. Cattle will not touch it nor even goats. In a healthy state, the vine has few enemies. I have only found two—snails and a long thin brown caterpillar-like grub, with a horny head. Will the people take it up? I think they will; already it is being tried by them in different villages on a small scale, but not on any systematic plan.

I am inducing people to visit the Government Plantations, and see for themselves. People are beginning to talk about it, and from what I can hear, a good many attempts will be made next rains.

As regards Dodaung I have not gone into calculations, nor mentioned the percentage of deaths, and number of plants put down, simply because a great many were planted under conditions which, as we now know, were hopeless. Further, a good deal of ground, viz., about 43 acres, had been thrown out.

In March 1884 there were in four blocks of Dodaung (105 acres) 3,709 plants alive, of which only 52 were over two feet high, and 400 of these were destroyed by fire in May. During the rains of 1884, 1,700 plants were put down in the reduced acreage of 63 acres, and now there are 3,030 plants alive, of which 236 are over two feet high (62 of them are over 4 feet high). I have also put down cuttings of *Erythrina Indica*, of which 100 are alive, and will be planted with vines in June 1885, and before the end of April, I hope to have another hundred down.

KYAUNGDAUNG.

In March 1884 there were 430 plants alive in this small plantation of 3 acres; 260 plants were put down in the rains of 1884; and

in February 1885, 580 were alive, showing a percentage of deaths of cuttings amounting to 33 per cent as against 36 per cent last year.

No record of the height of these trees was made in March 1884; but in February 1885, out of a total of 580, over 289 were more than four feet, and 103 others between one and four feet high. Here the soil is remarkably good; more trees are springing up fit for planting, and next year probably 150 more plants can be put down, bringing up the total to 730 trees, which gives about 243 vines to the acre—rather more than the number per acre on the Malabar method of planting.

Supposing all these vines in fruit, and allowing 1 lb. a tree, these three acres would give a production of 730 lbs. of pepper, worth at least 365 rupees for three acres, or an average of say 120 rupees per acre.

No comparison exists between this and the production of paddy, either as regards labor or profits. To any one, who can afford to wait and work up his ground, fruit trees can be used for growing the pepper vine with just as much success as any other tree, and with the double result of fruit from the tree and the vine.

An easier or more paying cultivation does not exist.

I think Kyaung-daung may be considered a thorough success. It is not as if the fruiting of the vine were doubtful; that is an ascertained fact. From some trees in Sandoway 5 to 7 lbs. of pepper are gathered annually. I have done my best in travelling about the district to explain the advantages, method of culture, &c. As I have already noted, its cultivation is here and there being attempted. On the arrival of the Thuglys with the land Revenue rolls, I took the whole of them to visit the gardens and explained the principal points. A number of the inhabitants of Sandoway have also visited the spot.

Sandoway, with its network of creeks from Sandoway to Mai, wants nothing but a valuable production of this sort to bring it forward from its present backward position. Boat or canoe transport would cheaply bring the pepper to any central point at very little cost, and we might then hope to see a little more trade in the district. If Government should feel inclined to sell or lease Kyaung-daung now that the vines are well established there, I think there would be plenty of applicants. I should then simply continue the experiment on the best part of Dolaung, at the same time testing the Malabar method of planting in straight lines on cuttings of the *Erythrina Indica*.

LIMING.

By DR. A. P. AITKEN,

Chemist to the Highland and Agricultural Society.

THE action of lime, whether in diminishing the amount of organic matter in the soil, or in liberating the potash from clays that are rich in that constituent, is clearly in the direction of assisting and hastening the weathering process. When the organic matter is so abundant as to bear an undue proportion to the mineral matter in the soil, and to render the land too retentive of moisture, whereby it does not receive sufficient aeration, and is liable to become sour, the effect of liming is to counteract the sourness, hasten the decay of organic matter, let in the air, and transform it from a cold and wet soil into a warm and dry one. Trenching and draining accomplish the same end, and in the reclaiming of heath and moss land, liming is employed to supplement these operations.

In the case of retentive clay soils, where draining fails to dry the land sufficiently and disappoints the hopes of the farmer, the action of lime by rendering the clay more porous increases in a marked degree the efficacy of the drains. In the carrying out of these ameliorations, the quantity of lime applied may be very great, and, even from five to ten tons per acre may be found to be productive of great benefit, but there are grave doubts as to the economy of applying lime in such enormous quantity in a single operation. Liming is a laborious process, and it is natural that a farmer should desire to get it done once for all; but there can be no doubt that in most cases where heavy liming is indulged in, there is a great loss of lime from its being run out of the soil in too great quantity. The tendency of lime to pass down through the soil is familiar to all farmers, and while its efficacy in many cases depends upon its permeating and purging the soil, yet it is liable, when too heavily applied to be run off the surface or through the drains before it has sufficiently done its work. While lime remains in the soil there is an upward and downward soaking of lime salts which, especially in the case of clay soils, is of very great importance, and it will seldom occur that one heavy liming is as good as two lighter ones. As a rule, it ought to be the aim of the farmer to keep lime as near the surface as possible, and therefore in ploughing it in, it should not be too deeply buried, and after it has been left for some time, and lost its causticity, the land should be harrowed so that the lime may be intimately mixed with the superficial layer of the soil; and it is evident that if lime is to be kept in the soil, a half liming once in five or six years is better than a whole liming once in ten or twelve.

The remarkable improvement in the physical character of such soils as we have been considering, caused by the addition of lime even when applied in large doses, has doubtless led to the too general and too plentiful use of that substance in agriculture, with the result that many soils have been impoverished thereby. As a rule, ordinary soils, in fair condition, seldom require lime, and when lime is applied too liberally, the apparent benefit resulting from its use is apt to be misinterpreted. It has caused many to suppose that liming has the effect of adding fertility to the soil,

whereas we have seen that it is chiefly a means for making the soil yield up its substance more abundantly. The rapid exhaustion which overtakes a soil of average strength when persistently limed is well known, and has given rise to the proverb that "Liming enriches the fathers and impoverishes the sons." There is truth in this as there is in all proverbs, but it is not the whole truth, and we cannot dismiss it with that remark. It is equally true to say that alcohol is a poison, but farmers still continue to use both lin and alcohol, and so long as they use neither in excess, and at the same time take proper means to nourish both their bodies and their land, there is little to fear from the moderate use of either stimulant. Unfortunately, it is too frequently the case that lime is put upon the land in deference to old established custom, and without any precise knowledge of the need of it, much less of the quantities which it is most profitable to employ. As a rule it is a safe practice to follow well-established precedents, but in order that it may be continuously successful, the conditions surrounding it must remain the same. This is by no means the case with agriculture, which during these later years has been rapidly altering its character, so that customs which suited very well the long rotations and restricted cropping of the past, are not equally advantageous when applied to the more intensive agriculture of the present. In the old days, when farmyard dung and vegetable composts were almost the only manures put upon the land, the very large amount of organic matter contained in these substances rendered the application of lime almost a necessity; but at the present time when light manures are so much in vogue, and when the area of arable land is in excess of the proportion which the dung produced on the farm is capable of manuring, the amount of organic matter in the soil may be reduced to such an extent as to lower even seriously the condition of the land. In such circumstances, the application of lime tends to aggravate the evil, and there is no doubt that a blind adherence to the old custom of liming, and especially of heavy liming, has entailed much needless expense, and, in many cases, has been productive of injury rather than benefit to the soil. An ordinary loam, in good condition, contains from 5 to 10 per cent of organic matter, and unless the amount is in excess of that proportion the application of lime is not indicated.

*Of course there are exceptions to this rule, as, for instance, when the loam rests upon a retentive clay, for in such a case it may be of more importance to increase the porosity of the subsoil than to augment the organic matter in the soil itself. There are also cases in which the application of lime is needed as a kind of medical treatment, and this is notably the case with soils affected with 'finger-and-toe.' Recent researches into the nature of this disease have shown that it is correlated with the existence in the soil of a minute organism which feeds upon the roots of turnips and other allied cruciferous plants, such as the charlock or wild mustard; and that it prevails in soils which are too frequently under turnips, or allowed to become foul from the growth of cruciferous weeds. Lime is the only substance that has been found capable of coping with this pest; and where frequent turnip growing is practised, it is found necessary to apply lime on soils which otherwise do not require it. It is a common experience that the application of lime does not always prevent or even diminish the ravages of 'finger-and-toe,' and in some districts the prevalence of this disease, notwithstanding the plentiful use of lime, has compelled farmers to diminish the amount of turnip-growing very considerably.

It cannot be said that such a state of matters is much to be regretted, for the days when turnip-growing formed the basis and backbone of agriculture are rapidly passing away, and the greater attention which is now being paid to the improvement of pasture, the consumption of grain and artificial feeding stuffs, the pulping, chaff-cutting, skilful mixing of fodders, and last, but not least, the making of good ensilage, have contributed to render the farmer comparatively independent of the turnip crop. Desperate efforts to grow a costly and precarious turnip crop on land not naturally suited for it are no longer necessary; but the moderate growth of turnips is still a great advantage, and where good turnip land is infected with 'finger-and-toe,' every effort should be made to counteract the disease rather than abandon the growth of turnips altogether. That lime should sometimes fail to be a sufficient cure may be due to a wrong mode of applying it, and this is a matter which deserves attention. Thus it is found that when lime is immediately applied to the turnip break, it does very little to diminish the disease, but when applied on the oat stubble it does better, and that it rarely fails to check the disease if applied on the lea.

This last method of applying lime has many advantages. It enables the lime to be spread with great uniformity, and in an open season, when there is still growth upon the grass, there is very little loss of nitrates, and when the land is ploughed for oats, the shallow furrow required for that crop prevents the lime from being too deeply buried, so that before the turnip seed is sown the whole surface of the soil has been thoroughly subjected to the action of the lime.

The quality of lime varies very greatly, according to the nature of the limestone from which it is derived. The quantity of actual lime ranges from 40 to 90 per cent, so that not only do some kinds of lime contain half as much real lime as others, but it is usually proved that poor limes contain large quantities of magnesia, and the application of that substance, so far from doing good, may be positively injurious. All limes contain some magnesia, and it is a constant constituent of the ash of plants; but magnesia salts are very little needed in the soil, and may be present in quantity sufficient to constitute a plant poison.

As to the modes of applying lime, there is room for considerable difference of opinion, and, of course, much depends upon the object in view: but for general purposes, the chief thing to be attained is fineness and uniformity. The usual practice of carting the hot lime on the land, and depositing it in little heaps has some disadvantages. The heaps are not equally slaked, and the spots on which they rest are severely burned. To secure equal slaking, they

INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA :—SATURDAY, MARCH 21, 1885.

[No. 12.]

Crop and Weather Report.

[FOR THE WEEK ENDING THE 11TH MARCH 1885.]

General Remarks.—There has been slight rain during the week in some districts in the Punjab, the North-Western Provinces and Oudh, the Central Provinces, Bengal, and Assam. Some rain has fallen also in Madura, North Coorg, and Kurrachee.

Harvesting continues in Madras, and, except in Bellary and Anantapore, the standing crops are generally good. In Mysore there is a scarcity of water, both for rice sowings and for cattle. Fodder is also becoming scarce.

The rabi harvest is in progress in the Bombay Presidency, in the Central Provinces and in the Berars, and has begun in the North-Western Provinces and Oudh, where it promises well. In the Punjab rabi prospects are generally very good. In the Central India and Rajpootana States the crops are in fair condition. In Bengal the rabi crops are expected to yield a good outturn. Boro paddy promises well; tobacco is being cut, and sugarcane-pressing continues. Ploughing for next season's crops is in progress in some districts. In Assam ploughing operations are well in hand. Sugar-cane is being cut and pressed in the Ganhati and Dibrugurh districts.

The public health is generally good. Prices are as a rule steady, but show an upward tendency in parts of the Punjab.

Madras.—General prospects fair, except in parts of Bellary and Anantapore. Cholera and small-pox prevalent in many districts.

Bombay.—Rabi harvest nearly completed in parts of Poona, Satara, and Belgaum; in progress in other districts; standing crops injured by mildew in parts of Nasik and by rust in parts of Shikarpore; scarcity of fodder in 3 talukas of Dharwar, and of drinking water in 5 talukas of Dharwar and one of Kaladgi; cholera and small-pox in parts of nine districts; cattle-disease in parts of 6, and fever in parts of 12 districts.

Bengal.—Slight rain fell in several districts; it has facilitated ploughing operations for next season's crops; harvesting of rabi crops continue, and a good outturn is on the whole expected; boro paddy is doing well; pressing of sugar-cane is still going on, and tobacco is being cut; price of rice is almost stationary; cholera and small-pox prevail in some districts, otherwise public health good.

N.-W. Provinces and Oudh.—Harvesting has begun; outturn promises well; markets well stocked; prices steady.

Punjab.—Slight rain in some of the districts; health and prospects good; prices rising in Ferozepore, Lahore, Rawul Pindie, and Peshawur, and stationary in other districts.

Central Provinces.—Wheat harvesting is in full swing, linseed having been all reaped; prospects continue favourable; price of wheat in Raipore is now 40 seers per rupee; weather slightly cloudy; days getting warm, mornings and evenings pleasant; crops progressing favourably; health good; prices easy.

British Burmah.—A little cholera in Akyab, Promé, and Thongwa districts; small-pox prevalent in 2 towns, Henzada and Thayetmayo; sporadic in 2 or 3 other quarters; a little cattle-disease in Akyab, Bassein, and Thongwa districts; otherwise health of province satisfactory.

Assam.—Mornings and nights still cold; days becoming perceptibly warm; sugar-cane being cut and pressed; ploughing operations for new in progress, but rain wanted to facilitate ploughing operations; public health good.

Mysore and Coorg.—No water in tanks for rice sowing; water and fodder for cattle becoming scarce; public health fair; prices rising slightly in parts. Paddy nearly threshed out; grain light; rain needed for coffee blossom; fall in price of coffee and cardamoms in local markets.

Berar and Hyderabad.—Weather getting hot; rabi harvest continues; prospects favourable; wheat 22 and jowari 26 seers per rupee.

Central India States.—Rabi crops good; opium collection commenced; weather and health good; prices stationary.

Rajpootana.—Opium crop in north-west pergunnas withering up; disease among some crops in one pergunna reported; health good.

Letters to the Editor.

MR. CASAMAJOR ON BROWN COAL AS A DECOLOURIZER.

TO THE EDITOR OF THE SUGAR CANE.

SIR,—In the November number of the *Sugar Cane* is an article by me on experiments with bone-black, vegetable charcoal, brown coal, &c., to show their decolourising effects on solutions of raw sugar.

I write now to say that brown coal has certainly a greater decolourising effect than I had stated. It may also be that by proceeding differently from the method I used, bituminous coal, anthracite, &c., may also give improved results. As to brown coal, there is no doubt that my results were too low. Within a week, Mr. D. M. Service, the agent of the "Sugar Appliances Company" of Glasgow, was two days in my laboratory, to show the decolourising effect of brown coal. He treated two solutions of raw sugar, each with 10 per cent of brown coal. One of these was of Hilo-hilo mats of about 86 co-efficient of purity. The decolouration was equal to 83 per cent. The other sugar was a muscovado of 88% cost of production. The decolouration with the latter sugar was equal to 60 per cent.

The only things which Mr. Service did to obtain these improved results, beyond what I had done, were, in the first place, to use moist brown coal, while I used this material dry; and, in the second place, to leave the sugar solution a longer time in contact with the brown coal. The samples of brown coal I had received from Glasgow came in paper bags by mail, and the material was consequently dry. The brown coal used by Mr. Service contained, according to his estimate, about 25 per cent of water.

As to the power of brown coal to facilitate filtration, the Hilo-hilo sugar filtered pretty well with 10 per cent of brown coal. Mr. Service thinks that with that particular sugar the filtration would have been better with 15 per cent of brown coal.

As to the muscovado sugar, 7 per cent of brown coal gave an unsatisfactory result, but 10 per cent gave a good cake, with a flow equivalent to $2\frac{1}{2}$ gallons per square foot of filtering surface.

All the solutions passed through very clear. I must also add that the solutions from muscovado sugar were afterwards filtered over bone-black, and that the filtered solutions showed that the one treated with brown coal gave a much better colour than the untreated liquor.

I could not give an opinion as to the value of brown coal as a decolouriser. This depends entirely on the price at which a refiner can actually buy it. As an additional amount of bone-black can always give a decolourising effect equal to that due to treatment by brown coal, every refiner can calculate for himself the comparative cost of using either brown coal or an additional quantity of bone-black.

As to Mr. Service, I will here take the opportunity to congratulate the "Sugar Appliances Company" on their choice of an agent. He is entirely free from the habit of gross exaggeration, too common with persons seeking to introduce new processes. His manner conveys the impression that he is truthful and straightforward, and therefore worthy of confidence.

I hope soon to send you a communication on another subject.

Yours very truly,

P. CASAMAJOR

New York, December 7, 1884.

Editorial Notes.

VETERINARY art seems to have been practised in India long before the advent of Europeans to the Far East, and it was left for Mr. James Mills, Inspector of Cattle Diseases, Madras, to light upon a curious little treatise on this subject, written in the Tamil language on the leaf of the palmyra or *kadjan*, the original author of which is said to have been a *rishi*, or Hindoo sage, and which Mr. Mills has translated into English. Although the prescriptions given in the quaint pamphlet will not add to our knowledge of veterinary science, some of them are remarkable for the cruel methods adopted by the ancients for the alleviation of pain in dumb animals. We may instance one for the cure of anthrax, or Loodiana disease, which is prevalent throughout India:—"Tie a bundle of straw, light it up, and with it burn the jaw of the animal. Internally, give the following medicine:—Bring a blood sucker and remove its head. After all the blood is passed out of its body, boil it well with varigoo rice, squeeze well by the hand, and give to the animal a piece about the size of a wood-apple. Keep the animal in the shade, and well covered."

THE following report has been received regarding the prospects of the wheat crop in Mysore:—"Mysore Durbar supply following approximate statistics—wheat cultivation, acreage 21,740; average annual outturn per acre; 516½ lbs. probable outturn per acre 1884, 350 lbs.; total estimated outturn, 1884, 6,082,720 lbs."

A FYZABAD correspondent writes:—"The Horticultural Show here was quite a success; the flowers were delightful. Mr. J. D'Cruz's roses were fine specimens, and his collections of cut-flowers were tastefully arranged; in many cases the arrangement of cut-flowers was not good, being too crowded and void of foliage. The vegetables were all that could possibly be desired. Mounster cabbages, English carrots, peas and turnips, really made one hungry; whilst the beautiful roots of celery were finer than any we recollect having seen in England. The potatoes and onions exhibited were beautiful specimens. There was a fair collection of fruit. The enormous bunch of plantains exhibited by Moonshee Khadir Buksh called forth general admiration. Garden tools there were none; we should have liked to have seen some. Mr. Gokulchund, the Municipal President, and Baboo Raghunundun, Honorary Secretary, deserve great credit for the trouble they took to make the show a success. This is the first Exhibition of the sort we have seen in Fyzabad, and if others to follow depend on the success of this one, it will not be the last. The 'management' were a little late in getting their notices round; otherwise we are informed the exhibits would have been much more numerous. The following is a list of the prize-winners:—

"*Flowers*.—Mr. D'Cruz; Major Forbes; Gooptar Park; Miss Fallen; Colonel Woodcock; Major Collum.

"*Vegetables*.—Colonel Woodcock; Public Garden; Narain Mali; Mr. Fox, 100th Regiment; Major Forbes; Mr. D'Cruz; Dyal Mali, N. I.; Khoob Chund; Lotoy Mali.

"*Fruits*.—Khoob Chund; Moonshee Nadir Buksh; Manick Baboo, 1st quality; Manick Baboo, 2nd quality; Colonel Woodcock; Public Garden; Pundit Kishen Lal; Narain Mali; Ramadhi Mali; Ganesh Morao; Khanroy; Ramsaroop Morao."

THE Liverpool Cotton Association has declined the request of the Calcutta Cotton Trade Association to reduce the Liverpool standard, in consideration of the fact that the Bengal crop has been seriously damaged by the October rains. It is pointed out by the Liverpool Association that the standards are not made from last year's crop, or, indeed from any particular crop, and if altered from time to time, complications of a very serious nature would arise. The standard ranges from "fine" to "middling fair," and in cases like the present, where the crop proves to be inferior in quality, the only safe course for shippers is to sell their cotton on the basis of a lower grade.

ONE of the most interesting subjects with which the last review of the administration of the land revenue department of the Central Provinces deals, is the subject of cattle and cattle-disease. It seems that the lands set apart at the time of settlement as pasture ground for village cattle are diminishing periodically, owing to encroachments, made by cultivators upon the available pasturage. The inroads made by malgoozars and villagers have also attracted the notice of the Deputy Commissioners of several districts, and steps are immediately to be taken to prevent a recurrence of the practice, which ultimately tells on the condition of the cattle in the province as will be shown a little further on. The malgoozars have no right to appropriate to their exclusive use what was devoted for the benefit of a community, and land taken from the *ghotán* has been ordered to be restored to its original purpose in some of the villages. The malgoozars go a step beyond this, and reserve the grass on the village pastures for sale. On this subject the Commissioner of Jubbulpore says:—"The Government reserved waste and forest lands are used also as the principal grazing lands for cattle, the village uncultivated waste lands not sufficing for the purpose, and gradually undergoing diminution as cultivation spreads. In a way, these reserves suffice; but it is impossible to see the village cattle at the end of the hot weather, and not to feel convinced that if the present small cattle are to be improved, they must be better fed: and that they will only then be properly fed when a store of food is raised and laid up for them. At present there can be no question that vast numbers die of starvation and the weakness caused by insufficient food."

UNDER these circumstances there can hardly be a doubt that to insufficient food may be attributed the chief sources of disease among cattle. On this subject, the Commissioner of Chuttagurh remarks that the considerable mortality among cattle which occurred during the past year, was partly caused by the continuous heavy rain, and partly by the fact "that an insufficient fodder supply brought the cattle to a low state, and predisposed them to disease. The loss in all the districts has been so heavy as to appreciably raise the price of cattle, and to be a subject of universal complaint. From inquiries made from individuals as to actual losses among their own herds, I should estimate that in some villages as large a proportion as 20 per cent of the cattle have been carried off, and that in few villages has the loss been less than 10 per cent. Separate application has been made for sanction to assist the people, where necessary, with *tucoaves* advances." The Director of Agriculture in his report says that the principal cause of this heavy mortality was pleuro-pneumonia, induced by the excessive dampness of the season, but it is just as likely that the emaciated and weak condition of the cattle predisposed them to sickness. In the Nerbudda Division also, we are told the cultivators have lost a great many plough bullocks, and the Commissioner is of opinion that "the decreasing supply of grass, and perhaps also of salt has something to do with it. That forage for cattle cannot be had in sufficient quantity can be easily known from the fact that the price of grass has everywhere enormously increased of late years." Another reason for the mortality may be found in the fact that proper care is not taken of these animals, and the people do not show sufficient intelligence in segregating those which are diseased. "The people hardly believe," says the Commissioner, "in sanitary precautions as likely to affect their own health: and it will take time to convince them that it is to their direct interest to treat their cattle more carefully, and to provide for their sustenance more liberally."

THE Deputy Commissioner, Balaghat, draws a graphic picture of the causes of mortality among plough cattle in rice-growing districts. "As a rule," he says, "during the hot months the cattle barely subsist on the especially scanty herbage then to be found in the cultivated tracts, with some allowance of rice straw. Cows are sent away to the pastures above the hills, but the bullocks generally have to take their chance. When the rains come on, they are put to the plough, and given a little extra food in the shape of *mehwa* and *chaff*;

but for nearly two months they are kept working in the mud below and the drenching rain from above. The first month is taken up in the first ploughings, and the second in making liquid mud, knee-deep, for the rice transplanting. The only animals that can bear up against this kind of life are the exceptional few that are really well fed and cared for during the whole year. Everywhere, in the hills and plains alike, the cattle-sheds in the rains, with rare exceptions, are several inches deep in mud impregnated with urine and dung. In these, for three months, the cattle have to pass the nights. The roads and paths through the villages are worse: so that with great difficulty, the cattle can find a dry standing-place."

.

Now when we come to reflect that this highly undesirable state of affairs is brought about mainly by the insufficiency of grazing lands, the prospects are not at all cheering when it is known that with every year, the cultivation of excess waste progresses, and the number of plough cattle to maintain becomes larger than the diminished pasture lands will support, it becomes a matter of necessity to adopt special measures for the supply of fodder. In this matter of cattle-fair, the report says:—"It would seem as though the very facility with which fresh cattle can be obtained to replace those which are lost, encouraged carelessness. Some of the cultivators in the Balaghat district buy and sell cattle at the beginning and at the close of every ploughing season. Every year large droves of cattle pass through most districts, on their way to local marts. Although no accurate statistics are available, the importation of cattle into these provinces and the number of head of cattle which are sold at the numerous cattle-fairs seem to be very great. Bullocks are imported from Berar, Malwa, Bhopal, Bundelkhand, Cuttack, from the Feudatory States on the eastern marches, and from district to district. At the great cattle-fairs of Garakhota and Kurai in the Saugor district, there was a considerable increase in the number of sales registered during the year under review. The Deputy Commissioner says that about 40,000 head of cattle were sold at the Garakhota fair which was held in February and March, and lasted four weeks. The Kurai fair is a weekly one: and between 40,000 and 50,000 cattle change hands there during the year. At Rahatgurih in the same district a small cattle-fair is held in the rainy season, where buffaloes are chiefly sold; and purchasers come from as far as Chuttisgurih. There are cattle fairs held at Mahankali (close to Chanda), Sonagaon in the Nagpore district, Dewalwarra in the Wardha district, Tumsar in the Bhundara district, and at many other places."

These cattle-marts, it may be incidentally observed, are the only kind of fairs which do not seem yet to have suffered from the changes in trade effected by the railways. In every district there are held annual fairs or bazaars of a general kind, which are no less frequented than they formerly were. The reason is that the ordinary local markets are now better supplied, that people travel more than they used to do, and that they commonly resort to the large towns for the purchase of imported goods, in the certainty of finding there a wider range for the exercise of their choice.

.

THE formation of laterite of the oxydation of ferruginous rocks is thus noticed in a paper on the geology and mineralogy of Malacca by the Rev. J. E. Tenison Woods of Australia. The paleozoic rock is largely mixed with poor iron ores, and where the surface water charged with carbonaceous matter has come into contact with these ores, they have been oxydized and converted into a red and reddish brown limonite called here laterite. This laterite has been a geological puzzle to most of those who have written on the geology of the Malayan peninsula. It is remarkable what a variety of guesses have been hazarded as to its origin. Some writers who have pretended to offer an explanation seem purposely to have obscured their meaning from inability to deal with the difficulty. It has been called volcanic, and regarded as a tertiary outpouring of basalt, and so forth. As already stated, the real character of the stone is simply due to the oxydation of a ferruginous series of rocks. The formation which has mostly supplied the materials for the laterite is the stratified paleozoic slates, and

the granite in contact with them. It is a decomposed rock. Water and air have been the decomposing agents. It is a most significant fact that there is no evidence whatever of recent upheaval from the sea, or even marine action. It would be hardly possible for this laterite or limonite with silicates of iron to be in course of formation without entombing some marine remains had they been in contact with them. Malacca is no exception to the general rule throughout the Malayan Peninsula that there is no evidence of recent upheaval in all the great extent of its coast line.

.

A RETURN was lately published, giving an account of the imports and exports of the respective French and Portuguese colonies, from which it appears that, as regards the French possessions in India, the total value of all imports and exports is only 89 lakhs. Of this, 53½ lakhs come under the heading of foreign trade, and 35½ lakhs under that of the coasting trade. This appears to have been about the average figure for the last five or six years. Of the imports, only 1½ lakhs come from France and 1½ lakhs from the United Kingdom, whilst 8½ lakhs come from the Straits Settlements, and 9½ lakhs from ports in British India, the trade with the other French-Indian possessions only amounting to half-a-lakh. Of the exports, 22½ lakhs went to France, 1½ lakhs to the United Kingdom, 4½ lakhs to Reunion, 6½ lakhs to the Straits Settlements, 24 lakhs to ports in British India, and a little over half-a-lakh to other French possessions in India. Turning to the Portuguese possessions, for which the latest return is that of 1882-83, we find that the total value of all imports was 26½ lakhs, and that of exports 17½ lakhs. The total customs duty collected on imports during the year was Rs. 20,737, almost the whole of which, with the exception of Rs. 191 for salt and military stores, came under the head of liquors. The total exports to foreign countries amounted to only one lakh, but those to other Indian ports came to 16½ lakhs. The import trade during the year was considerably above the average, and included railway materials to the value of 5½ lakhs. Our Portuguese neighbours live in the hope that when the railway from Bellary to Marmagoa is finished, the trade of their little port will be largely developed.

.

IN the report on the operations of the Department of Agricultural and Commerce, N.-W. P. and Oudh, we find that owing to the release of the Awa estate from the Court of Wards in October last, the experiments conducted on the reclamation of usar for the last five years by Mr. W. J. Wilson, Executive Engineer attached to this Department, have now been brought to a close. They may be held to set definitely at rest many questions regarding the possibility of the reclamation of usar on an extensive scale, and as such to be of great value. Large as the cost, spread over several years, may collectively appear, it is in the end more economical than frittering away smaller sums in a spasmodic way on unsustained efforts with subsoil drainage, deep ploughing, manures, and various crop. Mr. Wilson's conclusions briefly are, that where canal silt is available it can be used for usar reclamation with every prospect of success; and that the only other remedies feasible are the enclosure of the land for reclamation by the uninterrupted spread of usar grass and possibly with salt-bush and arboriculture. Under arboriculture again, *kikar* in moderately bad usar and *reunja* and *chaunkar* in bad usar are the only trees which have given notable results. Two plots of usar land were, with the sanction of Government, taken up towards the end of 1882 and enclosed. Out of several salt-bushes put down last year one only survives, but that is noticeable as growing well and strong in the open on a bit of usar on which there is no sign of any other sort of vegetation.* The rains of 1883 were unfavourable; but this year the usar grass is making head, and there are a fair number of young *kikar* trees.

.

IN the matter of arboriculture there would appear to be an unusually large sum realized by the sale of loppings and fellings in the Agra and Allahabad Divisions. Receipts from the sale of fruit, too, are much in advance of last year; the Benares Division heading the list as usual with nearly half of the total income for the Provinces. The net cost under this head was

Rs. 21,587-0-3, against Rs. 27,312-12-4 in 1882-83. The number of trees planted out were far in excess of those of the year previous. It is noticeable, however, that the ordinary country mango is extensively planted, and that little or no attempts are made at introducing varieties, if grafts of several varieties were used for avenue-planting a considerable income, in excess of the present, would be realized from the sale of fruit and also from the sale of young grafted trees from nurseries. The attention of district officers will be invited to the subject, and efforts made to extend in this connection the nurseries established by different municipalities. In the matter of irrigation there is nothing special to notice save the fact of an apparatus invented by Mr. Twigg, the Collector of Hamirpore, for watering forced plants without destroying the fence. Briefly described, it consists of a long tin tube sheathed with split bamboos. One of these is carried on each water-cart, and one end having been thrust through the thorn fence, the water can be easily delivered from the earthen pot furnished with a nozzle fitting into a leather bag which is attached to the outer end of the tube.

.

EXPERIMENTS with agricultural implements were conducted as in previous years at Cawnpore, and for the most part on the lines indicated in last year's report. The kharif season of 1883 was characterized by scanty and ill-distributed rain and in consequence by a general outturn less than in the preceding year. The deficiency in rain, however, served to bring into greater prominence the advantages of deep over shallow ploughing; one ploughing with the improved farm plough giving 18 per cent increase over two ploughings with ordinary native plough. Thus the additional cost of an improved plough is quickly recovered in an increased yield. In the cotton experiments following the observation that the cotton plants on the outside ridges of the fields were the finest, plots were formed with ridges 3 feet apart. A large increase was obtained by that method from New Orleans and Nankin seed over plots where the seed was sown broadcast or in drills. The largest yield was 188 lbs. clean cotton to the acre obtained from selected and acclimatized New Orleans seed. The manufacture of sorghum sugar was carried out with no more difficulty than that experienced with ordinary sugarcane juice; about 1,600 lbs. were manufactured and sold well. The rabi season for 1884 was marked by an entire absence of rain, the crops having been dependent, for germination even, on artificial irrigation. Yet the maximum outturn, amounting to 51 bushels, was the largest ever known on the farm, and the average was likewise in excess of previous figures.

.

In the manure experiments cowdung proved to be the cheapest in comparison to its value as a fertilizer. Green soiling experiments were conducted on an extensive scale and results of value recorded. The experiments in deep ploughing were as successful as in the case of the kharif plots. An experiment of some interest was that of planting wheat on ridges alternating with fallow spaces, a substitute for manure being looked for in constant cultivation of the fallow spaces. This system has lately been experimentally revived in England and gives some promise of success. Laboratory experiments with ushr soil showed that, to a certain extent, sulphate of lime (or gypsum) induced fertility, and larger plots are being treated *in situ*. Ensilage received continued attention, and jwar forage was preserved successfully for eight months in simple pits dug in the soil. Elaborate experiments were made as to the feeding value of ensilage and figures given to show the cost of ensilaging, the net result being that 8,000 lbs. of jwar forage cost as ensilage Rs. 15-14-8 at a time when the same quantity of dry and inferior fodder was selling for Rs. 25. Amongst implements, the Duplex plough, devised at the farm by the Superintendent, gave excellent results, and the pattern of water-lifts in use was still further improved. The farm was well represented at different agricultural fairs, and has sent out large quantities of improved seed wheat. The indents for drugs for the Medical Department on Saharnpore Gardens were in amount double those of the previous years, and the distribution of seeds and plants showed an increase. Several additions of interest were made to the gardens, including the *Rhus vernicifera* (Japan varnish tree) and *Fucca draconis*. Improvement

by selection of hot-weather vegetables and the acclimatization of European vegetables gave good results, particularly in the case of the Scotch Champion potatoes. Salt-bush (*Atriplex nummularia*) is now an established success and seeds freely.

.

INTERESTING and instructive experiments were conducted in fruit culture, at the Lucknow Horticultural Gardens, and with several varieties of cottons; 14 new varieties of acclimatized flower seeds were added to the garden catalogue. An interesting experiment with *dab* grass showed that by scraping the surface, or "chiling," as practised by natives, an advantage of 10,320 lbs. per acre per annum is obtained over the plan of allowing it to grow and then cutting with a sickle. The arboricultural and exotic nurseries show good results and progress.

.

As regards sericulture, Messrs. Lister and Co. are pushing forward operations with energy, and have already completed far more than they stipulated for. Two hundred acres of mulberry have already been planted, and so far back as March last 200 acres more of land were cleared for planting, while there was an abundance of seedlings, amply sufficient for planting out a thousand acres. Fifteen and-a-half ounces of seed used during the year produced 1,076 lb. of green cocoon, or 67 lb. to the ounce of seed, at a total cost of Rs. 110-9-5. From the cocoons reserved 20 lbs. of seed were produced, worth at Rs. 5 per ounce Rs. 1,600. The management have hitherto felt the want of a sufficient number of rearing-sheds, which are now being rapidly constructed. As in the previous year, prizes were offered for the best cocoons produced under cottage cultivation, but the result was scarcely satisfactory, and there appears little hope of cottage cultivation ever becoming popular so long as cultivators are expected to rear the worms in all stages from seed. In August and September, 1883, a quantity of freshly-imported American tobacco seed was sent for experimental cultivation to seventeen districts of these provinces. The result cannot, however, be said to have been generally successful, as only three of the districts—Pertabgurb, Gonda, and Unao—have reported favourably. The plants are here said to have flourished throughout, and in the end yielded a good crop. At Pertabgurb the cultivators are reserving seed for future sowings.

.

A CONTEMPORARY says that few people even know that the Malta lemon grows in India, yet that grown here differs in no way from the lemon of Malta, Sicily, Naples, Nice, Spain or Portugal. The care, moreover, with which it can be cultivated by budding on the common *Khattu* trees; the rapidity with which it grows—in three years rising to 10 feet in height and being laden with fruit; above all the utility of the fruit as an anti-scorbutic in unhealthy seasons, ought to make it far better known than it is. In soldiers' gardens, jail gardens, and hospital compounds it would be invaluable. In the Etawah jail gardens, for instance, three years ago Dr. Bonavia, who has studied the growth of the orange and lemon in India perhaps more than any one else, found only one lemon tree, which he had sent there previously, among many thousands distributed in different directions, from Lucknow. From this one tree, in three years, he has now 300 large trees in full bearing, sufficient to supply not only the jail but the whole neighbourhood with their fruit. If so much can be accomplished by individual effort, how much more might be effected by the aid of a little official impulse?

.

WE take the following from Messrs. Wm. Jas. and Hy. Thompson's circular on Indian Tea:—About 35,000 packages have been catalogued for sale since the 12th inst., 1,100 of these being Ceylon and 2,200 second hand and re-printed parcels. At the commencement of last week the tone of the market was affected by the continued dulness of the country trade, and prices for all but the best teas showed weakness; subsequently there was more demand, and rates for all descriptions closed firm. This week there has been healthy competition

with a general desire to buy at previous prices, but the dealers do not yet find sufficient demands upon their stock to compel them to follow up any advance, so that the movement of the market, although upward, is scarcely perceptible. Comparing latest sales of fair to good Pekoes and Broken Pekoes with transactions earlier in the month, $\frac{1}{2}$ d. to 1d. improvement is quotable; fine Souchongs and Pekoe Souchongs are also dearer, but common sorts are unchanged, while for low Broken, prices are weak and irregular. Ceylon Teas of the new crop are beginning to arrive and meet with ready sale: quality is not of equal merit throughout, but the bulk of the teas maintain their high character. The average price of 4,500 packages sold this year is 1s. $2\frac{1}{2}$ d. per lb. Deliveries are going on well.

.

The following memorandum of the Agricultural Department, relating to the different varieties of wheat and the chief places and soil in which they are produced, has been issued:—

"It is quite impossible to reduce the numerous varieties of wheats grown in India to a uniform and scientific classification. Every district has its own names, and even if the same names are used over an extensive tract, they are often found, as is remarked in a recent work in which the subject is carefully examined, 'to be applied in different places to totally different varieties.' Sometimes the name denotes the color or texture of the grain; sometimes a peculiarity of the ear or stalk, or the character of the cultivation. But more often it is merely descriptive of the locality in which the grain is produced, or from which it is supposed to have first come. All varieties, whatever be the local names, may be primarily classed as white or red, hard or soft, and this fourfold grouping is recognised in the European trade. Adopting this classification, it appears that the soft white wheat, which commands the highest price in the English markets, is grown to great perfection in Northern India, Rajpootana, and Guzerat, and is commonly known under the names of *daudi* or *daudikhani*. It prefers a rich loam soil, well manured and irrigated, and a moderately severe winter. Soft red wheat ranks next in order of value in the European markets. Numerous varieties of this class are common in Northern India, and it is often sown intermixed with barley or gram. But the most valuable variety, under the name of *pissi*, comes from the Central Provinces, especially from the Nerbudda Valley. The predominant soil in this tract is a heavy black loam or 'cotton' soil, which owing to its fertility and its capacity of retaining moisture, will produce excellent crops in years of average rainfall without manure or irrigation. Of the hard wheats, the white variety is much prized by natives. It is less known in Northern India than in the Deccan and Southern Mahratta country. More delicate than the hard red wheat, it requires careful cultivation and irrigation. Hard red wheats also are little known in Northern India; but under the title of *kuthia* wheats they form the predominant class in Rajpootana, the Central Provinces, and the Bombay Presidency. They are preferred to the soft wheats for consumption by the natives, and up to recent years commanded a higher price. The European demand for soft wheats has, however, brought the class of soft wheats, of which *pissi* is the best known variety, into greater favour with the cultivator. In the Central Provinces it was once not uncommon, it is said, for a ploughman contracting for service to stipulate that he should not have to eat *pissi* wheat more than twice a year. Now, a ploughman who demanded it twice would certainly not receive it, as its price is now at least 5s. a quarter higher than that of the hard wheats. This is an interesting illustration both of the care with which the native cultivator selects his seed, and of the quickness with which he adapts himself to the changes of the markets. A reference to Messrs. McDougall & Co.'s report on experiments conducted by them with Indian wheats, on behalf of the Secretary of State, will show that they assigned the first place in order of merit to the white wheats, and the second to the soft red. The former is on a par with English wheat and the best Colonial wheats. The soft red wheats are 4s. or 5s. the quarter less valuable. The information summarised in the preceding paragraph places the home of the former in the Punjab, the Mahrat Division of the North-Western Provinces, and of the latter in the Central Provinces."

SILAGE IN INDIA.

We have noticed in previous issues, the origin, scope, and extension of the practice of ensilage in Germany, France, England, and India, and having given the heads under which we propose to discuss the subject, we will take them in order:—

I.—CONSTRUCTION OF SILOS.

Silos are nothing more than reservoirs for the preservation of green fodder. They are either wholly under ground or wholly above ground, or partly above and partly under ground. The practice obtaining in this respect in all the countries named above differs so much that no one particular plan can be recommended for adoption. The practice must vary to suit circumstances. In England, for instance, the plan most in favour and generally adopted is to convert old barns into silos. Attempts have sometimes been made to construct silos of wood and iron. In the report of the Bombay Director of Agriculture, mention is made of an iron boiler or reservoir improvised for the occasion to serve the purposes of a silo. Whatever be the details of silo-building, the points to be kept in mind in the construction of a silo are, that the bottom and sides of the pit should be made perfectly water tight. The sides should be perpendicular and perfectly smooth; and speaking generally, the corners should be rounded off. The length, breadth, and depth of a silo would, of course, depend on the quantity of green fodder required to be stored, the nature of the farm house economy in the cost of construction, and other local conditions. No hard-and-fast rule can be laid down for the construction of silos, much being left to individual experience. We would venture to suggest that in Bengal, for instance, old thatched houses and other buildings that disfigure almost every village might be utilized for such a purpose.

II.—FILLING AND COVERING SILOS.

When a silo has been built, the next question that arises is, how best to fill it? In this also, the practice varies. Some chop the green fodder before pitting it, while others prefer pitting it unchopped. At any rate the varieties of green fodder found in England admit of its being pitted without being previously chopped; so also in Europe generally. In America where maize is commonly used for ensilage, chopping is more generally resorted to than elsewhere. The size of the maize plant does not admit of its being stored unchopped; but grass and similar fodder could be stored, chopped or unchopped, to suit the convenience of the farmer. It may, however, be generally stated that if a crop be pitted unchopped, a great deal more treading and weighting would be necessary than if filled chopped. The latter process would, however, leave much less air-space.

While the crops are being pitted to fill the silo, particular attention should be paid to tread them layer by layer. This would pack the fodder up well, and serve to distribute more evenly the pressure caused by the weights placed at the top.

It is a general rule with farmers who resort to ensilage, to mix salt with the pitted fodder; and, as a convenient means of giving salt to farm animals, this method of doing so would meet the end in view. But whether it tends in any way to preserve or improve the fodder, is not definitely known. On this head, however, Mr. Jenkins, of the Royal Agricultural Society, writes:—"But if water of any kind or in any combination is in excess, my impression is that the addition of salt will injure the quality of the silage."

After filling the silo with fodder, the next process is the covering and weighting. In this as in the other processes, the practice must vary to suit circumstances. Some cover it up with boards, spread sawdust, earth or straw over them, and finally place weights above all. Others dispense with boards altogether, and use stones only, which both cover and weight the underlying mass. In fact, diverse contrivances are resorted to in covering and weighting the mass. The pressure caused by the weight varies from 40 lbs. to 2 cwt. per square foot. The mean, of course, lies between these two extremes, but this would be verified by experiment and careful observation.

The object of covering and weighting is simply to exclude the air from outside into the mass which, it is thought, would spoil it. The smooth perpendicular walls and rounded corners which

we have recommended for general adoption in all silos would, we think, serve this purpose by presenting a smooth surface, thereby allowing even for shrinking of the green fodder.

FOREST ADMINISTRATION IN COORG, 1883-84.

We have before us the report, which shows on the whole that the administration of the forests in Coorg during the past year was satisfactory. The survey of the Ghat forests was nearly completed in May 1883, but some parts of the line will have to be revised. No additions were made during the year to the notified Government forest area, which remains at 233 square miles. Breaches of forest law were not frequent. The forest establishment is said to be too small for the increased work put upon it. The measures taken for the protection of the forests against frequent fires were on the whole satisfactory, especially when it is considered that the year was rather trying during the unusually long dry season from November to April. Natural reproduction was rather backward, and below the average. The production of seedlings under *lanthana* was not noticeable, as the seeds had not sufficient light for germination. The year was a good one for planting, and much good work was done in artificial reproduction. The teak plantations were enlarged by 126 acres, and the sandal plantations by 107 acres. The planted area now stands at—

Teak	429 acres.
Sandal	278 "
Ruel	85 "

As an illustration of the value of these areas for the sandal alone, it is shown that about 20 trees got to a ton, and as they do not require much room, it is thought that at least 400 trees per acre will remain for the final crop. Putting the price per ton very low at Rs. 300, the value of the crop will be Rs. 6,000 per acre. Sandal is said to come to maturity in 40 years. Discounting at 4 per cent, the value of these plantations is Rs. 1,300 or Rs. 3,31,400 for 278 acres. The cost up to date has been Rs. 22,900; this accumulated at compound interest at 4 per cent for 40 years will amount to Rs. 1,09,942, to set off against the magnificent total of Rs. 16,60,000. This calculation of yield and profit shows that the sandal is a valuable and remunerative tree of the forest.

The experiments with exotics were not quite as successful as might have been anticipated. A good proportion of the *ceara* seed germinated, but are reported to have been eaten by rats, and only about 200 plants remain, which are growing satisfactorily. Such of the *cocoa* plants as survived transplanting, are said to be doing well. They seem to have withstood the dry season wonderfully well. Kutampole, where the *cocoa* was planted, is situated at an elevation of 500 ft. above sea level, and appears to be quite a suitable climate for the *cocoa*.

The experiment with *Cinchona* planting, which was made mostly on land abandoned by coffee planters, was not successful. Those plants, however, that established themselves, were doing fairly well. The experiments with *wattle* (*dealbata*) were not successful. The plants did not bear transplanting, and died when put out almost to a plant. The Java figs and plants of *figia pinnata* are said to be growing, but they suffer during the monsoon. Some seeds of *syncarpia laurifolia* were sown in beds and germinated well. There are about 200 plants put out. The financial results of the year may be summed up as follows:—

	1883-84.	1882-83.
	Rs.	Rs.
Receipts	87,742	1,38,022
Expenditure	75,042	64,783
Surplus	12,700	73,239
Percentage of expenditure on receipts	85.4	49.9

The revenue is less than the estimate by Rs. 22,258. This is said to be owing to the non-sale of sandalwood, prices having gone down unprecedentedly. This is said to be due to the large sales which have been made in Mysore for some years past. The proportion of expenditure to revenue is much larger than in any previous years, owing, it is reported, to increased expenditure on productive works, such as plantation, which cost Rs. 19,393. But this is represented as capital well laid out, and expected to give a splendid return in due time. The

receipts under timber have again increased. Those for 1882-83 were Rs. 26,221; for 1883-84, Rs. 36,771, shewing an increase of Rs. 10,550 on the previous year's.

Taken altogether, the present administration report shows satisfactory progress, and better results are looked for in coming years.

THE ANNUAL REPORT OF FOREST ADMINISTRATION IN THE PROVINCE OF ASSAM FOR 1883-84.

The Conservator, in his forwarding docket, states that the report has been "made as short as possible without omitting any essential information." This is a step in the right direction, though more might still be done; the Assam Forest Reports have not hitherto been conspicuous for brevity or conciseness. From the concluding portion of his letter, however, we think we can discern a lingering fondness for the old style in the Conservator's breast, as he states that the shortening of the report is "in accordance with the wishes of the Chief Commissioner." It is not our purpose to review in detail the Forest work done in the Province, but merely to remark on a few of the prominent points, and to note where we think the report itself is susceptible of still further curtailment and improvement. Firstly, owing to the headings of work done, being in very small type in the margin, instead of having a separate heading in bold letters, it is very difficult to find the account of the different classes of work in the divisions. Next, there is too much detail given, regarding fire conservancy, plantations, and especially roads; surely it is not necessary, nor of any general use or interest, to put in the petty details as to length of roads and cost as given at pages 18, 19, and 20; most of this might have been given in a separate statement, or better still, not given at all. Efforts are being made to reduce the cost of demarcation; that of the Nowgong District, Rs. 20 per mile, is "high;" of the Sibsagar division the cost is Rs. 10-4, and is "damned with faint praise" as being merely "reasonable, considering the great difficulty of obtaining labor in this part of the Province." In the Lakhimpore District it is "very excessive," viz., Rs. 49 per mile, and it is satisfactory to know that an explanation has been called for; but is there any necessity to state this in the Annual Report? As far as one can gather it is one of the principal duties of Forest Officers in Assam to plod along over miles of demarcation lines every year, and a sort of record is kept up as to how many miles have been inspected by each officer. This is as it should be. A note is also kept of the number of days each officer is "absent on tour," so that no doubt, a healthy rivalry is established, and there must be strenuous efforts on the part of every officer to "cut the record;" it is satisfactory to note that the present Conservator's record is better than that of any other officer, with the exception of the Durrung officer; but then the Conservator's camp was absent for 33 more days. Harking back to demarcation inspection, we note that the Lakhimpore District Officer has only visited 41 miles out of 109, "which is altogether insufficient." It does not avail him that there was a press of other work and no elephants; the Conservator cannot accept this as a "valid excuse;" the work is apparently much more important than any other, and should have been done on foot, if there were no elephants available. The Cachar divisional boundaries have also been insufficiently visited, only 12 miles inspected out of 68 miles; a very bad "record." The officer, it is interesting to know, "suffered from sore feet for the greater part of the working season," but this is considered a most unsatisfactory excuse; from the nature of the ground apparently, elephants could not be used, and as the officer's feet were "sore," he could not walk. We note that the cost of demarcation in Cachar is Rs. 13-9 per mile, which is "somewhat high." On page 8, it is stated that an attempt was made to ascertain the number of trees in the Chirangduar reserve, and much detail is given with what object it is difficult to conceive, as immediately after, the Conservator throws discredit on the work, and from his "personal observation" (which is evidently of much greater value than any countings), "knows that there are nothing like that number of sal trees above 3 ft. 6 inches in the reserve." Surely in such a case it would have been better not to mention the work at all in the

annual report. It is satisfactory to note that the establishment is on a better footing, and each member has now "definite duties;" before then, we can only imagine them to have been indefinite. An appendix, V, is given consisting of 5½ pages of close print which shows the different beats of the guards; this is most interesting, and we are sure, if every province followed this example, the Forest Department would get together in time a mass of information which would be of the greatest benefit in furthering the cause of scientific forestry in India. To show the importance attached to the posting of the forest *chuprassies*, or guards as they are called, it is laid down that none of them may be transferred without the "previous sanction in writing" of the Conservator; note that it must be "in writing"—verbal orders are not to be considered, apparently. This is very well in its way, but we are inclined to doubt whether it will not be found to hamper the Conservator, and unduly interfere with the powers of the Divisional Officer; it does not appear to be in the spirit of the ruling in the Forest Code; thus Section 19 provides that "the control of the Division will be vested in a divisional officer;" and this surely means that he has the power to transfer the establishment in his division. Seeing that Section 44 lays down that, he has the power to appoint guards, and Section 47 to fine, not only guards but "any of the members of the subordinate staff," it would seem to follow that he has also the power of moving them as he may think fit. Fire conservancy was not very successful during the year, owing to the unfavourable season; 39,000 acres being burnt out of a total of 134,000 attempted to be protected. The greater part of the area burnt was in the Goalpara Division, where the burning was intentional, and the divisional officer is mildly censured for not having the sympathy of the inhabitants with him in his labours. The Conservator appears certain that all that is wanted is sympathy, and there will be no more forest fires in Goalpara. The expenditure on fire protection in Assam has been very heavy already; we observe that up to the end of 1883-84, Rs. 51,000 have been expended on protecting some 95,000 acres; still there is no doubt it is money well spent; there must be an ample return in the shape of increase in natural reproduction. The private forest owners of Assam must be a singularly obliging class of men, as it would seem that they do not object to the Forest Department burning their forests; but it would be well to get their "previous sanction in writing," or complications might arise. There has not been much progress in artificial reproduction, only 34 acres having been added, of which 21 were caoutchouc and 13 timber trees; it was intended to extend the charduar caoutchouc plantation by 200 acres, but the Aka raid stopped all work. As before mentioned, too many details are given about planting works, such information as that about "sisu" (query? *sisu*) "not doing well on the low ground," is quite out of place; what is required in an annual report is a general but succinct account of progress, omitting all petty details and dealing only with great matters. Looking at the general results of planting it cannot be said to have been very successful in Assam, considering the number of years it has been carried out. The plantation form states that on the 31st March, only 1,223 acres have been planted at a cost of Rs. 1,04,577, or Rs. 85 per acre. At first sight this would seem to be a fairly large area, but when area is dissected, it is found that from this number 1,025 acres must be deducted as they contain caoutchouc and bamboo; this leaves only 198 acres planted with timber trees at a cost of Rs. 1,278 or Rs. 112 per acre, not a very large area but in cost per acre decidedly so. A great deal of road-making has been done during the year—a very good thing in such jungles as Assam contains; but there is no necessity to take up two pages of the report with uninteresting details as to their length and cost. There is one fact upon which the Conservator is to be congratulated, which is, that, as stated by him in para. 141, "no timber operations are any longer carried on in Assam by direct departmental agency." This is a step in the right direction; when it is fully recognized, that a forest officer's time should be entirely occupied in taking care of his forests, and not in supplying the public with wood and charcoal, &c., then, and not till then, will there be any real progress in forestry in India. The revenue has been less than that of the previous year by Rs. 37,160—not a great decrease, but as the expenditure has been much

greater than in 1882-83, there is a great falling off in the surplus; that for 1882-83 being Rs. 76,782 as compared with Rs. 11,893 in the present year. This is ascribed to the dull state of the timber market in Bengal, and to increased expenditure under live and dead stock, demarcation and improvement of forest, establishment, &c., and the Government of India in their resolution on the report consider the results satisfactory. The Conservator has devoted nearly two pages of the report to a very uninteresting account of his tour; this consists of the driest details of his progress, merely giving the date of arrival and departure at the different places, and a word as to the object of his journey. Surely all this might be packed away out of sight in the appendix. In the whole two pages, the only interesting fact is, that the Conservator reached Gauhati on the 21st January, and consulted the Deputy Commissioner about one of the departmental elephants which had killed a man! After this, follow the usual certificates of character of each officer, which are also to our thinking out of place. What general interest is there in knowing that certain officers had much improved in their management, and that others displayed very little zeal, or were sadly deficient in supervision of work, &c.? Such remarks should be made in a separate report to the Government if necessary, or more properly still, communicated in a kindly spirit to the officers themselves. Of course in the case of encomium, they do no harm; but censure, when made public in this way, does more harm than good. It is surely not the intention of Government that a man should be held up in this way, before the eyes of the world, on charges which are nearly always general, and may possibly be mere matters of opinion, based on insufficient data. The body of the report occupies 36 pages, which might easily have been cut down to about 25 pages; the next 29 pages are taken up with the forms ordered in the Forest Code, and then come 40 pages of appendices! A great number of these need not have appeared at all in the report:—for instance, Appendix IV is simply a stupendous account in minute detail of demarcation work and of each officer's demarcation inspection record; the time alone is wanting to make it read like an account in the field of a fifty-mile walk! Appendix V we have already alluded to; the guards appear like so many "sweet cherubs" who are "watching over" the various forests; this, though absolutely necessary for the divisional officer to have by him, is altogether out of place in the annual report. Appendix VI is hardly necessary, and VII and VIII not at all so; IX, X, XI and XII are laws, that is, rules published under the Forest Act, and have nothing to do with the annual report; the Forest Act itself might as well have been printed. Appendix XIII is a wonderful collection of statistics of value to divisional officers alone, and not ordered in the Forest code. The rest may be necessary, but we are not in a position to know; but in the case of XVI, the Chief Commissioner thinks that the information might be condensed, and at "pages 106, 107 the same figures are in some cases reported three times over." Statistics are most ensnaring; when once they are indulged in, the liking for juggling with figures always remains; and if not kept down results in madness, not perhaps, to the man himself, but to the unfortunates under him; who, taking no interest in them, are yet obliged to make out vexatious *nakshas*, year after year; and whose time is generally occupied towards the end of the year in dismal anticipations of the statements required with the dreaded annual report. We noticed not long ago that Sir Charles Aitchison remarked on the length of reports; let others remark on it, and in time we shall arrive at some sensible method of recording the year's transactions, which shall take the place of the dreary plan now adopted.

SOAP AS AN INSECTICIDE.

PROFESSOR RILEY, the State Entomologist of the Washington Department of Agriculture, has found, after a long series of experiments, that common soap is about the best and cheapest insecticide that can safely be used in gardens. Alcohol is too expensive, and volatile oils more or less injurious to plants; experiments with some of the latter, such as naphtha, turpentine, &c., having resulted in the total destruction of some orange-trees on which they were tried. Crude petroleum, he says, destroys the bark; and even the refined oil in hot sunshine

completely strips the tree of leaves. A mixture of kerosine with milk, which is subsequently diluted with water, was found to be apparently innocuous; but it requires trouble in the mixing, and care in using. The Professor makes the following remarks with regard to soap:—The value of soap as an insecticide has long been known; and the experiments which I tried with it were made chiefly for the sake of comparison with those made with other substances. The results, however, were so remarkable that I feel warranted in saying that taking into consideration its efficiency as a means of destroying scale insects, its effect upon plants, and its cost, there is at this time no better remedy known than a strong solution of soap. In my experiments whale-oil soap was used, and the solution was applied by means of a fountain pump to orange trees infested with the red scale of California. In the strongest solution used the proportions were three-fourths of a pound of soap to one gallon of water. The mixture was heated in order to dissolve the soap thoroughly; and the solution was applied while yet heated to about 100° F. The tree upon which the experiment was made was very badly infested, the bark of the trunk being literally covered with scales. Four days after the application of the solution, I examined the tree very carefully, and could find no living insect on the trunk of the tree, and only a small proportion of the coccids on the leaves appeared to be still alive. I was unable to examine the tree again personally, but three months later Mr. Alexander Craw, of Los Angeles, made a careful examination of this and some other trees upon which we had experimented and on this one he was unable to find any living scale insects. Taking into consideration the extent to which this tree was infested, and the fact that but a single application of the solution was made, the result is remarkable. In another experiment the solution was made as in the above, and then an equal amount of cold water added. The tree experimented upon was similar to the one used for the former experiment. Four days after the application no living insects could be found on the trunk of the tree and only a very few upon the leaves. In fact, the experiment was as successful as could be expected, it being very difficult to reach every insect on the leaves by a single application. When Mr. Craw examined this tree three months later he found but few living insects on it. As a result of all of my experiments with soap, I recommend the use of it in the proportion of one-fourth pound of soap to one gallon of water repeating the application after an interval of a few days. If a cheap soap be used which can be obtained for from four to six cents per pound, the cost of the remedy will not be great compared with what is to be gained.

Miscellaneous Items.

REPORTS from Cachar and Sylhet mention that rain was beginning to be badly wanted for the tea in those districts.

A NEW reservoir, 191 feet square and 40 feet deep, to hold nine million gallons of water, has been made at Maliga Kanda, the hill in the centre of Colombo.

A LARGE amount of stores of all kinds is being brought into Rawul Pindie, so it is probable that prices will not be so exorbitant as was at first feared.

ALTHOUGH the Amir's visit is some three weeks off, the prices of provisions in Rawul Pindie are daily rising. Gram has gone up 8 annas a maund in two days, and everything else in proportion.

It is stated that the British India Steam Navigation Company's ship *El Dorado*, which was wrecked on the Birlings, off Lisbon, had on board, in addition to 600 tons of war stores, £80,000 in gold. An attempt is being made to recover a portion of the valuable cargo.

ACCORDING to the weekly report of the Assistant Superintendent of Police, North Malabar, dated 24th January 1885, "large quantities of pumice, originating no doubt from the volcanic eruption which occurred in the Straits in 1883, are drifting to the north-west along the Malabar Coast."

WE learn that the Government of India have approved of the abolition of the Saldapet Experimental Farm proposed by the local Government. In expressing their approval, they have given it as their opinion that the improvement of Indian agriculture must be as a rule based on native traditions and implements, but not on those of Western countries.

THE North-West Elephant Kheddah has wound up well, making a catch of nine elephants after a chase of fully 40 miles on the 3rd, when operations came to an end. The total catch was 44, of which 36 are alive. The Maharaja's best season was 29, so Mr. Greig has distinguished himself.

GROUNDNUTS are coming in from the districts to Pondicherry in much larger quantities than was expected, and the crop available for export is now estimated at between 400,000 and 500,000 bags, or about two-thirds of last year's out-turn; the price, however, is high, being, for the present, Rs. 21-4-0 per candy, delivered at Pondicherry.

WE are sorry to learn that over the greater portion of Parnas district, long black caterpillars have attacked the rapeseed and pea crops—the former when it was nearly ripe for reaping, and the damage done in some places has been so complete that the ryots have grazed down the crops with their cattle rather than pay the cost of gathering.

ABOUT twenty-one million acres of land in the United States are now owned by members of the nobility of Europe, chiefly Englishmen. How many acres are held by untitled aliens is not known. In the opinion of the Committee on Public Lands of the House of Representatives, this large alien ownership is an evil which should be prevented by legislation. The passage of a bill to remedy this state of affairs is under discussion, but with little chance of success.

THE Government passed the following order on the report of the late ploughing competitions held at Sydapet:—"The Government agree with the suggestions made by the committee, and observe that the arrangements, which were made at this exhibition for testing the general efficiency of the various implements used as well as the skill of the competitors, were successful. The proposal to hold the next exhibition in August, instead of in December, should be considered by the Director of Agriculture."

THE Government having directed the transfer to the Museum of the art exhibits which Mr. Havell, the Superintendent, collected during his recent visit to the South, he has pointed out to Government that such a step will not be in the interests of the School of Arts, as it is essentially necessary that the exhibits should be in the building where the drawing classes are held, and the location of a museum and drawing class in one and the same building, as obtaining at South Kensington, does not exist at Madras.

AN old Indian writes to the *Standard*:—"I see that your special correspondent states that our soldiers in the Soudan suffer greatly from the dry air of the desert, that their faces get parched, and that they are tempted to waste their precious supply of water. I have lived for many years in India, and perhaps my experience will be of a little service when I say that a little olive or other vegetable oil rubbed over the lips and face will prevent the parched feeling complained of, and that a small piece of lime or lemon in the mouth will check thirst. It ought not to be a difficult matter to provide a lemon or two for each soldier leaving Suakim for Berber."

THE shareholders of the Colar Gold Company have decided, after some opposition, to ratify the agreement which had been made for them by the liquidators. Under this agreement they received £1,000 in cash, and 38,000 shares from the Indian Consolidated Company, who are thus placed in possession of a property from which great expectations are entertained; based on what has been already done in the same district. The Colar shareholders have already had a return of 6d. a share, and the present arrangement came on them in the nature of a pleasant surprise. In their own hands their property "was as dry bones;" it now remains to be seen whether the Indian Consolidated Company can kindle the vital spark.

THE exhibition of art workmanship for the Mayo prizes annually given at Bombay does not appear to have been very successful last year. There were 13 specimens of Kutch silver repousse work sent in—two by Comaral Mowjee, and 11 by Hajje Dood, while 11 ornaments were also sent by a silversmith at Hoshiarpore in the Panjab. The first prize of Rs. 150 was awarded to Comaral Mowjee for a *lotan*, the form and design of which were said to have been far above the average of Indian work. Only one competitor came forward for the prize offered for enamelling, but his work was not considered sufficiently good to entitle him to a prize. It is to be regretted that one of the oldest art industries of India should attract so few competitors.

THE Agricultural Department of the Privy Council have published an official estimate of the yield of the cereal and other crops in Great Britain for the year 1884. England and Wales together produced a wheat crop of rather more than 77,887,000 bushels; or 1.19 bushels per acre above the estimated ordinary yearly average yield. For Scotland, the estimated total produce amounts to 2,348,000 bushels; at an average rate of 34.17 bushels per acre; or 1.48 bushels above the estimated ordinary average yield. The new total of the results for wheat in Great Britain is thus brought up altogether to 80,235,000 bushels; the estimated average rate being 26.26 bushels per acre, or 1.19 bushels per acre above the normal standard of production. The variations in yield have been remarkable; and, even within the limits of a single district, estimated quantities of from 10 to 44 bushels per acre have been recorded, according to the character and situation of the land on which it was grown, and the mode of culture pursued.

Mr. B. D. PLUMMER reported on January 13:—"At this time a Hladoo feast is going on, and our work is slightly impeded; otherwise all goes on well, and the lode in bottom of the mine is as good as reported last week. I informed you we should take down some lode from the hanging side. We have taken off 3 or 4 feet; the stuff is rich, and the lode looks healthy. Stamping goes on satisfactorily. We shall clean up at the end of this week, and the yield will come up to my expectation. We have treated all the old stuff which had accumulated before the trial stamping commenced. Surface work:—the masons are getting on very well with the foundations for the California stamp engine. In the first instance we intend to set up 12 heads; others can be added afterwards as they are required."

FARMYARD MANURE.

By DR. A. P. AITKEN,

Chemist to the Highland and Agricultural Society.

LONG before the exhaustion of the soil began to manifest itself, the attention of the husbandman must have been directed to the extraordinary fertilizing effect of the dung of animals, and advantage of this experience would no doubt be taken to increase the productiveness of some part of the farm. As population increased and fertility diminished, a regular system of preserving and applying farmyard manure would gradually take shape, and become of ever-increasing importance, until eventually it came to be regarded as the very foundation of successful agriculture. In a new country and on a strong, fertile soil, there is no inducement, there is no economy in storing and using farmyard manure—it is a superfluous labour; but in all populous countries, and notably in our own, where the soil has been reduced by centuries of cropping, the basis of farming is the manure heap. Although in these days, importation of artificial manures has made farmers less dependent on farmyard manure than formerly, yet it is still, as of old, the central system of the farm, and its careful manufacture, preservation, and use are more than ever deserving of careful attention.

Farmyard manure consists of the solid and liquid excrement of animals, combined with the straw or other substance used as litter, and when fresh consists of about one part solid matter and three parts water. About one-half of the total dry matter contained in an animal's fodder is found again in the manure, so that it is easy to estimate approximately the amount of manure produced upon a holding in ordinary circumstances when the amount of dry matter contained in the fodder is known. For every 1000 lbs. live-weight of the animals fed upon a farm, the amount of dry fodder daily consumed is about 24 lbs., and if we add to the half of that one-fourth for litter, *viz.*, 6 lbs., we obtain the sum of 18 lbs., which represents the total dry matter in the manure. To this has to be added three times as much water, *viz.*, 54 lbs., and we obtain a total of 72 lbs. wet manure per 1000 lbs. live-weight per day. This is only an average, for when animals are fed mostly on turnips, containing 92 per cent of water, the manure will be much wetter; if on hay, much drier.

The loss of dry matter which occurs in converting fodder into dung is mostly loss of carbon, which is partly burned in the animal's body in keeping up its temperature, and is partly stored up as fat and flesh. There is also a loss of nitrogen, which amounts on an average to about a fifth of the total nitrogen contained in the dry fodder, but which may be more or less, according to the kind and amount of fodder and the state of nutrition of the stock. There is very little loss of mineral matter. The potash contained in the fodder is mostly voided in the urine, while the phosphoric acid is almost entirely contained in the solid excrement.

The manurial value of the dung is influenced by various circumstances. In the case of oxen in forward condition, the loss is very slight, while in the case of cows giving milk and in the case of calves or other young stock, more than half the nitrogen and about two-thirds of the phosphoric acid are lost to the manure.

The general character of the dung made by various kinds of stock is also very different owing to the different kinds of fodder, and the more or less perfect mastication and digestion to which it has been subjected. Milch cows fed on watery diet produce a dung containing only about one-sixth or a seventh of solid matter, while the dung of most oxen fed on a dry diet contains about one-fourth of solids. Owing to the perfect mastication which takes place in the ruminating process, the constituents of the dung are in a fine state of division, and the whole forms a mass through which air does not penetrate, so that the rotting process goes on very slowly, rendering it a very slow-acting manure. It is called a cold manure, since there is no apparent heat generated during its very slow fermentation. On that account it is necessary to mix it with a large amount of litter, in order to keep it free and permeable to air, so that the rotting process may be hastened. The dung of horses is a dry dung, and more open and porous, so that it ferments very easily and heats rapidly. When too concentrated, the heating is carried so far as to kill out the ferments in the heap, and cause a loss of manurial matter.

The urine of horses is also a more concentrated material than that of cows or oxen, and therefore it is very advantageous that

the manure derived from oxen and horses should not be collected separately, but mixed together in a careful, uniform manner. The dung of sheep resembles somewhat that of horses, but it is somewhat drier, and therefore well adapted from counteracting the too fluid character of cow dung.

There are many questions that arise as to the making and using of farmyard manure. It may be asked whether fresh dung is not a better manure than that which has been preserved in heaps. It will usually happen that less loss of manurial matter occurs when manure is made directly on the field, inasmuch as the methods of preserving farmyard manure are usually imperfect. It cannot be said that the droppings left by cattle on a field are properly distributed; on the contrary, the manure is applied in about the worst conceivable manner. It remains for months protected by a hard resinous covering, and ferments with great slowness; it kills out the grass immediately beneath it, and renders that part of the pasture unfit for food for many months; the rank vegetation which grows on the spot next season is not acceptable to cattle, and the pasture becomes coarse and uneven. This might easily be avoided by a little attention, such as the employment of boys, or other unskilled labour, to scatter the dung and secure its more even distribution, or the removing of it altogether to the dung heap. The applying of fresh cow dung to the soil is not attended with any loss of substance, and in some cases is much to be preferred to any other method. This is especially the case when it is wanted to improve the mechanical condition of stiff clay soils; but, as a rule, some preparatory fermentation in the heap is very beneficial. The chief improvement that occurs to dung when heaped is the rapid rotting of the substance, whereby the hard straw or other litter is softened, and made more capable of yielding up its manurial substance to the roots of plants. The albuminoid matter in the heap is decomposed and converted into ammonia, and the ammonia is in turn converted into nitric acid, so that, from being a slow-acting manure, the dung becomes one of the strongest and most rapid manures on the farm. In cases where it is desired to prolong the action of the dung over a long period, it should be ploughed in fresh; but when it is wanted to expend itself chiefly on the crop to which it is applied, it should be as well rotted as possible. That the rotting process may be satisfactory, it is necessary that the manure heap be carefully made. It must be uniform throughout the whole mass, and this uniformity should be attained during the making of the heap rather than by turning it over at a later stage. When a heap is not uniform or equally fermented, the turning it over, although attended with some loss of ammonia, is to be recommended, as it is highly desirable to have the whole heap uniform; and the loss of the ammonia is not so great as is apt to be imagined from the pungent smell during the operation. When a manure heap is carefully mixed and layered in the making, and where there is a due proportion of litter and dung, the fermentation goes on equally through the heap, and there is no need of turning.

The preservation of farmyard manure is a subject which has been much neglected. There are now many covered courts and covered heaps; but as a rule the dung heap is exposed to the weather. In wet climates this is a great misfortune, as even with the greatest care, it is scarcely possible to prevent waste, and if there is no special care taken, as is usually the case, the loss of fertilizing material is enormous. An uncovered manure heap in a wet district is the biggest hole in a farmer's pocket. In dry districts the loss need not be very great; and if care is taken in the making of the heap, it may be quite unimportant. While a dung heap is maturing there is a constant evaporation of moisture from the hot mass, so that it is apt to become too dry; and where the heap is under cover, it becomes necessary to run over the heap with water, or, better still, with urine. In a dry climate the amount of rain which falls upon the heap just about compensates for the loss of moisture during fermentation. In order that there may be no loss in such circumstances, the bottom of the heap requires attention. The water in the heap gradually drops down, and flows away as a constant brown steam highly charged with potash salts, and this may occur when the upper parts of the heap is too dry. It is therefore necessary to have the heap placed upon a dry bed of earth or straw, or some absorbent material, and it should be surrounded with a gutter filled with this absorbent, and the earth or straw, or whatever it is should be frequently renewed, the soaked matter being tossed up on to the top of the heap. When manure is exposed to the rain it had better not be quickly fermented, as in the process of fermentation the great change which occurs is the increase of soluble matter, and as this is liable to be washed away, it is well that manure which has to stand long should be very slowly fermented. In such cases it should be packed closely together, and exposed as little as possible to the direct force of wind.

There are some substances which are valuable in preserving manure and hastening its decomposition, but unless the heap is under cover or exposed to very little rain, they should not be used. Chief among these substances is *gypsum*. The effect of gypsum is to prevent loss of ammonia, and it may also hasten the nitrification process. It is a safe substance to employ, and it should be sprinkled over the heap as it rises, so that it may ultimately be fairly well distributed throughout the mass. Carbonate of lime or marl may also be added with advantage, and even fresh lime may be safely sprinkled through the heap in small quantity (about 1 per cent), and if put only on fresh dung, there need be no fear of loss of ammonia. Fresh dung does not contain ammonia; it is only after fermentation has set in that ammonia is formed. The action of lime and its salts is to hasten the conversion of ammonia into nitric acid, so that nitrate of lime is formed, and as that is a very soluble salt, it would plainly be a mistake to encourage its formation in a manure heap exposed to rain and liable to leakage.—*North British Agriculturist*.

MR. T. NEILL ON SUGAR BOUNTIES.*

We commend to the attention of the Board of Trade in general, and Mr. Giffen in particular, a pamphlet that has been published setting out in brief and clear terms the whole "case" of the sugar trade as against the foreign bounty system. We do so not because we agree in all that this valuable pamphlet advances, but because we feel that the Board of Trade has not yet thoroughly understood the arguments that it contends it has finally answered. This will be at once evident from a summary account of the pamphlet itself.

The author, Mr. T. Neill, is a well-known and experienced sugar refiner; and he writes in a dispassionate spirit which will do his cause far greater service than the passionate and obviously biased denunciations that are far too common in this controversy. The issue of the pamphlet is explained in the words,—"At the request of a number of working men directly interested, as all workmen are, in the preservation of British industry, and directly and indirectly interested in the preservation of the special industries selected for attack by foreign Governments, and who desire to have in as short a compass as possible, the leading facts and opinions on the foreign bounty question presented to them, I have written the following pages."

There next follows an account of the "diplomatic efforts made by the Government of this country to obtain the abolition of the bounties," which provides an explicit summary of what diplomacy has attempted. Commencing with the declaration in 1863 of the French Government that "it is the desire of France, and no doubt of other countries too, to relieve the Treasury of a charge, the only effect of which is to permit refined sugar to be sent to foreign markets at a reduced price," the account tells of the five Conferences that were held in rapid succession, in the years 1864, 1865, 1866, 1868, and 1869; and how the series was then interrupted by the Franco-German war, but renewed in the years 1873 and 1874; in which year the French National Assembly "voted by a majority of 364 to 167 in favour of refining in bond," and again there were Conferences in 1875 and 1877, and invitations were issued for a final Conference in 1881, which only failed because Great Britain declined to assist on the conditions laid down by France. The fact that no less than nine Conferences for the abolition of bounties should have been held in 18 years, and chiefly on the initiative of the Continental Powers, is not quite in agreement with Mr. Neill's original contention that foreign Governments, by their bounty systems, have specially selected the British sugar industry for attack. Mr. Neill, however, is rightly of opinion that this record seems to show that "diplomacy has utterly failed to have the evil removed." But we must not therefore give up all hopes for the future; indeed, in our opinion, the very fact that so many attempts have been made at such short intervals goes far to prove that diplomacy may succeed in the end, for they show that among the nations concerned, there is at all events a will, if only we can find a way.

Working men, for whom this pamphlet is specially written, will profit not less than the Board of Trade authorities by the perusal of the clear account Mr. Neill gives as to "how the bounty is given," which is summed up in the general result that "fabricants," in the various continental countries, actually obtain a bonus of from 1s. 9d. to 3s. per cwt. In the description that follows of the effects of the bounties on raw and refined sugars respectively, the figures given are well worthy the close attention of the Board of Trade. Mr. Neill, indeed, assumes throughout that the bounties are the one only cause of all the results he tabulates, but among these results are two startling facts. The one is, that "the increase in the importation of soft sugar in 1884 over 1882 is 97 per cent;" and the other is, Mr. Neill points out, that "in 1864 the quantity of foreign refined sugar used in this country was only about 2½ per cent of the total quantity of sugar consumed. Under the bounty system the quantity has been gradually increasing year by year, until it has reached 20 per cent."

In regard to the effect of bounties on raw sugar, Mr. Neill is not quite so successful in his statement. This is much to be regretted, as there is plenty of exact evidence which he has not adduced. His adversaries are sure to take hold of the somewhat contradictory statement as to the "demand for cane sugar having materially fallen off, and that a very large percentage of cane sugar has been replaced" by beet—placed in such close juxtaposition to the statement that in 1864 we consumed 523,203 tons of cane sugar, and in 1884, 598,001 tons. But he is perfectly right in declaring that cane sugar can be produced at less cost than beet. He weakens his case by agreeing with Mr. Ritchie's Committee that cane cultivation in the West Indies is at all perfect, or that "no want of attention can be charged against the growers"—because, as a matter of fact, very much remains to be accomplished by way of improved methods of agriculture and manufacture in nearly every one of our West Indian colonies.

Mr. Neill states well and concisely the effects of bounties to the British consumer. "It ought to be clearly kept in view what amount of reduction in the price of sugar which has recently taken place is due to natural economic laws and what amount to bounties. To the reduction from the former cause the British consumer is legitimately entitled to its fullest extent, and neither the colonial producer nor the home refiner can, nor I believe does, make the slightest complaint. . . . To the reduction of price under the latter of the two causes mentioned above, viz., State aid or bounties, there is no system of political economy yet promulgated which asserts that the consumer has any legitimate claim. It is to the reduction from this latter cause alone that both the colonial producer and the home refiner enter their protest, and desire the Government to adopt an efficacious remedy."

In estimating the amount of fall in price due to bounties, Mr. Neill shows conclusively that the whole of the bounty received is

* Foreign Bounties: how they affect working men and consumers. By T. Neill. W. Hatchison, Greenock, 1884.

not expended in lowering prices, but only sufficient of it to enable the recipient to undersell English sugar in the English market; the remainder he retains, and the English consumer only gains that fall in price which is necessary to enable the foreigner to undersell the English producer. Mr. Neill does not enter into the wider argument as to the effect of bounties in causing overproduction and artificial glut of neutral markets. In discussing "the remedy," Mr. Neill has not noticed that the Select Committee did not, as he contends, report that a countervailing duty should be imposed, although he is quite correct in stating they reported in favour of manufacturing and refining "in bond." The international position, however, could not be better put than in Mr. Neill's words:—"Why, then, is it that when most of the bounty-giving countries profess a desire to abolish bounties on sugar, they still exist in every sugar-producing Continental state? The reason is, because they say no one State can individually cease to give bounties so long as its neighbour continues to give them, otherwise its manufacturers and refiners would be thrown out of the markets of the chief consuming country so long as that country is willing to admit bounty-fed sugar on the same terms as free-trade sugar." Mr. Neill next points out that France demands adhesion to the principle of countervailing duties, although England, "and, perhaps, Holland," are unwilling to agree to such a condition. Mr. Neill scores a decided point in reminding us that that Cobden's main argument was contained in the words, "we require corn at the natural price of the world's market . . . every source of supply freely opened;" and, on this he asks, "how can the natural price be restored to an article on which a bounty is given?" With the obvious reply that either the bounty must be abolished or the importing country must put on "a duty exactly equivalent to the bounty given."

The passages in this pamphlet showing that the particular countervailing duty proposed is not in itself contrary to free-trade principles; that it is not a protective duty; that in principle it could not be extended except to commodities that had received bounties; that it is not a retaliatory duty—are all clear expositions of the arguments with which Mr. Giffen must contend. In disposing of the objection that such a duty would be an infringement of "most favoured nation" treaties, Mr. Neill's chief argument is that the duty would be imposed on the bounty and not on the sugar, asserting that "the countries sending bounty-fed sugar would be treated alike. . . . If they wished their sugar admitted on the same terms as non-bounty giving countries, all they would have to do would be to comply with the conditions which this country insisted on in the importation of sugar, namely, that it should not be bounty-fed." His argument comes practically to a request to Government simply to place as an item in our Customs tariff—applicable to all nations alike—"Sugar, bounty fed, duty equal to amount of bounty received—all other sugars free." We are afraid, however, that our Customs authorities have already declared they can only take cognizance of goods as they receive them, and that while it would be possible to take beet sugar and allow cane sugar to enter free, it would not be competent for them to draw distinctions according to what takes place elsewhere, but of which they have no evidence in the goods themselves.

In regard to the benefits of which a countervailing duty is declared to deprive the consumer and the refiner, Mr. Neill points out that the advantage to the consumer is, after all, but infinitesimal—"four-pence in the year per head of population"—and that all that the manufacturer really needs is to obtain his raw material at equal prices to his competitors. He argues that even the mere threat of such a duty would at once bring bounty-giving countries to terms, and that in this respect it differs from more retaliatory tariffs, in that it destroys directly the effect of the bounty and thus cuts away the only cause of its existence.

Altogether the arguments are stated with a clearness, brevity, and force that is bracing, and, as we have said, the pamphlet must be carefully studied by the Government authorities if they wish to know what arguments are being, and will be, pressed forward to influence public opinion. "It is the abolition of bounties that is demanded. The countervailing duty is only a means to that end. If the Government can secure the abolition of the bounties by any other method . . . then such a duty will not be asked for." The great object is that sugar, whether as a raw material or as a commodity ready for consumption, should be obtained in England "at its natural price, and with every natural source of supply freely open." Mr. Neill's pamphlet is calculated to render valuable aid at the present time, and it should be closely studied not only by those who are agitating this question, but also by those advisers of the Government who have discountenanced further action in the matter. It appears to us that all possible pressure should be brought to bear on Government to place the whole question in the hands of a special Commission, composed of two or three unbiased and properly qualified experts, with instructions to negotiate forthwith for a Convention among the powers interested. With a full and firm conviction as to the end to be secured, such a special Commission would readily devise some efficient means.—*The Sugar Cane.*

WET WEATHER DETRIMENTAL TO THE HEALTH OF HORSES.

THE recent wet weather, although almost unseasonably mild, has increased sickness amongst live stock. Hard-worked horses, especially when burdened with long coats, become over-heated, and perspire exceedingly; the rough hair, in damp, close weather, interferes with healthy skin transpiration; animals not properly attended to when brought in from a heavy day's work, often stand throughout the night in what is virtually a wet, close-fitting blanket. If no worse trouble befall this chilling ordeal, the night's rest brings very inadequate refreshment, and the poor

animals proceeds to work next morning dull and inert. With less vigour or recuperative powers, other horses under such depressing circumstances are attacked with cold, cough, or sore throat, varying in type and intensity according to predisposition of the care or nursing bestowed upon them. Not only does the mucous membrane of the air passages thus become irritated, and animals are laid up with colds in the head, throat, or chest, but from the like exposure others suffer from catarrh of the bowels, and are gripped and attacked with diarrhoea. The damp, mild weather engenders still another class of ailments. Amongst hard-worked horses, both in town and country, swelled legs, professionally known as lymphangitis, are now common. Further illustration of retarded blood purification occurs in increase of rheumatism and of purpura, or transpiration of blood from congested weakened vessels of the mucous and skin surfaces. The wet weather has also multiplied the attacks of pink-eye, which has for three months prevailed, especially amongst the heavier class of horses, in London, and has increased the number of relapses and mortality. When most horses are dull, as they are apt to be in close, damp weather, slight ailments and premonitory symptoms are apt to be overlooked, and the horse, which should be rested and nursed, continues at work for one or two days, greatly damaging his chances of prompt and entire recovery.

How, it may be inquired, are horse owners during onervating damp weather to guard against such a chapter of ailments? Most, as pointed out, are traceable to impaired action of the important purifying skin functions. It will hence be essential to overcome as much as possible the mechanical difficulty which the skin has in doing its work in a damp atmosphere and with a low barometer. The close hair covering, saturated with moisture usually both from without and within, should be rubbed dry—an operation which, moreover, conduces to equable circulation. Excess of long hair, so seriously retarding drying, should be got rid of. Although it is injudicious to deprive horses exposed to all sorts of weather of the whole of their natural winter covering, there is no injury in trimming off the thick hair along the lower part of the body, the thighs, and arms, whilst long hair elsewhere may be singed off. While these processes are in operation, or diseases of any kind prevail, there should further be redoubled watchfulness for slight aberrations from health, such as the neglected meal, the staring coat, hot mouth, cough, or deranged bowels. And noting any such irregularities, the careful horseman will at once adopt some such appropriate treatment as an extra wiping, a dry, warm rug, or a comforting gruel with a stimulating draught.—*North British Agriculturist*.

THE THOROUGH-BRED HORSE—HIS ORIGIN AND BREEDING.

THE great son of Diomed, Sir Archy, did as much for the thorough-bred racehorse and turf in America as the Godolphin Arabian, King Herod or Matchem for that of England. Nearly all of the best horses in this country have been produced by his sons and daughters, and wherever stamina, quality, speed and great staying powers are shown, it would be found that there is a deep infusion of his blood. The best produce of the imp. Barb mare Sultana, whose dam and sire were presented by the Bey of Tunis to his Excellency President Jefferson, was Lady Burton by Sir Archy; she was the dam of the famous Couter Snapper, by imp. Chance, Robin Adair by Sir Archy, her own sire; Sidi Hamet, and Melli Melli by Virginian, son of Sir Archy and Moretrix, by Magog, son of Chanticleer, by imp. Wildair, Magog's dam by Symme's Wildair, son of Fearnought, by Regulus, by the Godolphin Arabian. Lady Burton's daughter, by Shyllock, son of Bedford, produced Maria Shepherd, the dam of Lilac and Tishamingo, by Leviathan; Macbeth, by Sir Archy, and Betsey Ruffin, by Virginian. Sultana is the only Arab or Barb imported into America which had any substantial reputation, and that came from the Archy blood. The most reputable of Potomac's get, he a son of Diomed, was Tenny Cockracy, and the best of her descendants were Yankee Doodle and Maid of Lodi, by Virginian, Creeping Kate, by Sir Archy, Betsey Harrison and Susette, by Aratus, son of Director, by Sir Archy; Aratus' dam, Betsey Hazell, by imp. Sir Harry, by Sir Peter, by Highflyer, by Herod, his grandam Timoleon's dam, by Saltram, by Eclipse, Susette produced Berthune, sire of Release, and Rescue, by Sidi Hamet, and Isola by Bertrand. Betsey Harrison was the dam of Denmark, the noted old racer by imp. Hedgeford. The value of the Diomed and Sir Archy blood can best be illustrated by giving a few instances of its value when inbred, almost incestuously so. Duchess of Marlborough, by Sir Archy, dam by Diomed, was a superior race mare. The best of her produce were Red Tom, by Bertrand, son of Sir Archy, and the good race mare Luda, by Medoc, a great grandson of Diomed. The famous Lady Lightfoot, by Sir Archy, bred a number of colts. Black Maria, Terror, Shark and Bay Maria were her best, all by a grandaun of Diomed, American Eclipse. Reality, by Sir Archy, was a famous race mare; the best of her produce were Medley, by Sir Hal, son of imp. Sir Harry, son of Sir Peter, by Highflyer, and Mat-on, by Alfred son of Matchem, Slender and Bonnets o' Blue, by Sir Charles, son of Sir Archy, his dam by Citizen. Slender and Bonnets o' Blue were superior racers, and the latter the dam of the noted Fashion. The famous Trifle, by Sir Charles, produced Gloriana, American Eclipse, and she produced Jack Malone and Pat Malloy, by Lexington, a horse with three direct crosses of Diomed through Sir Archy and Ball's Florizel. Lecompte, the first horse which ever ran four miles better than 7-30, was by Boston, dam Reel, by Glencoe. The great race mare Idlewild, the first mare to beat 7-30, running in 7-26½, had four direct crosses to Diomed through Sir Archy, Ball's Florizel, and Eclipse. She was the dam of Wildidle, by Australian, that ran four miles in 7-25½. Lexington, the first horse to beat Lecompte's time, running in 7-19½, has

three Diomed crosses, and is closely inbred to Eclipse, Herod and Matchem. Fellowcraft, the first horse to beat Lexington's time, running in 7-19½, has four Diomed crosses on his dam's side and is much inbred to the three great lines of blood. Florida, with the best record at four miles of any mare, has four Diomed crosses on the maternal side. Ten Broeck, by Phaeton, whose performances, one mile in 1-39½, two miles in 3-27½, three miles in 5-28½, four miles in 7-13½, have never been equalled, has no less than seven crosses of Diomed through his dam Fauny Holton. Drake Carter, the best long-distance horse now on the turf, has no less than fifteen Diomed crosses through his sire and dam; his three miles in 5-24 has never been equalled in the world. Eole, acknowledged to be one of the best race-horses ever shown, has seven crosses of Diomed through his best sons, Sir Archy and Ball's Florizel. Hindon, one of the best race-horses of modern times, has five crosses of the same blood, three through his dam and two through his sire, Virgil. Louisa, the crack three-year-old filly of last year, has four crosses of this desirable blood. Glenmore, whose three heats of four miles in 7-29½, 7-30½, 7-31 have never been equalled in the world, has three crosses of Glencoe and four of Diomed blood. Miss Woodford, acknowledged to be the grandest mare of our time—her two miles in 3-33, 3-31½, the best ever made—has nine Diomed crosses. Foxhall, one of the best race-horses ever bred in America, and winner of the Grand Prize of Paris, Cesarewitch and Cambridgeshire handicaps, has seven Diomed crosses. Wanda, by Mortemar, the crack two-year-old filly of last year, has seven Diomed crosses, and all of them are closely inbred to the three great strains of blood which originated and perfected the race-horse. Colonel Hoopes imported several other stallions: Dion, foaled 1795, by Spadille, son of Highflyer, by Herod, dam Faith, by Paoclet, son of Blank, by the Godolphin Arabian, out of Atalanta, by Matchem. He was a capital race-horse, but sired very few horses or mares. He, Col. Hoopes, imported Dragon, foaled 1787, by Woodpecker, son of Herod, dam Juno, sister to Diomed's dam, by Spectator. He sired the dam of Sally Walker and Dragon, dam by Truxton. Dragon died in Tennessee in 1812; also Druid, foaled 1780, by Potomac, son of Eclipse, dam Maid of the Oaks, by Herod, out of Rarity, by Matchem. He was a good race-horse. He was sire of Palafox, out of Mary Gray, dam of Wonder and Paoclet, by Tippoo Saib. Spread Eagle, imported by Col. Hoopes, was foaled in 1792 by Volunteer, own brother to Mercury, by Eclipse, dam by Highflyer, son of Herod, grandam by Engineer, son of Sampson, by Blaze, by Flying Childers, great grandam by Cade, son of the Godolphin Arabian. He was a superior race-horse, won the Derby in 1795, and was the only horse that beat the great Hambletonian winner of the St. Leger by King Fergus. Spread Eagle got some good stock, such as Maid of the Oaks, dam Annette, by imp. Shark; Floretta, dam by Hall's Union; Paragon, dam by Bellair; Red Eye, dam by imp. Shark; Adeline, dam by Whistle Jacket; Maid of the Oaks was dam of Young Maid of the Oaks, by Expedition, son of Pegasus, by Eclipse, and Active, by Woodpecker, son of Herod. Young Maid of the Oaks, bred to American Eclipse, a grandson of Diomed, produced Medoc, one of the best race-horses of his day, and a wonderfully successful sire. She also produced Cora, Midas, Highland Mary and Gipsy, all by American Eclipse, and Katy Ann, by Ogle's Oscar, son of imp. Gabriel, and Vixen, by imp. Medley. Cora was the dam of Lucy Toland, by Priam, and third Boston, by Cost Johnson. Gipsy was the dam of Pryor and his two sisters, by Glencoe, owned by the late Keene Richards, one of which was the dam of Glycours and Colossus, by imp. Sovereign, the other dam of Reporter, by Lexington Alumina, by imp. Eclipse, &c. Katy Ann, bred to American Eclipse, produced Lady Thompson, and so produced Traubyan, by imp. Trauby; Motto, by Barefoot, son of Tramp, by Dick Andrews, by Joe Andrews, by Eclipse, his dam Rosamond, Buzzard, son of Woodpecker, by Herod, out of Rossbery, by Phenomenon, also son of Herod; and Fiatt, by Hedgeford. Motto produced Nannie Lewis, the dam of Aldebaran; My Lady, dam of Onward, by Ringgold, and Sallie Lewis, all by Glencoe. The latter produced John Morgan by Sovereign, Hunter's Lexington, Glenrose, Susan Beane and Acrobat, all by Lexington; Lotta, by Hunter's Glencoe, the latter the dam of the good race-horse Glenmore, by Glen Athol, Glenmore being very much inbred to Eclipse, Herod and Matchem; Susan Beane produced, by Leamington, Surquhanna, Onondaga and the great unbeaten Sensation. Leamington was much inbred to Herod, Eclipse and Matchem, having twenty four crosses of Herod, sixteen of Eclipse and ten of Matchem blood, besides numerous others to the original sources of the three strains of blood. Sensation, in addition to the blood lines in Leamington, derives a very large infusion of the same blood on the maternal side, in addition to four crosses of Diomed. Col. Hoopes imported many other stallions and brood mares, none of which were of any great prominence as sires or matrons. Speculator, by Dragon, son of Woodpecker, by Herod, dam sister to Sting, by Herod, out of Florizel's dam, by C. gnot, son of the Godolphin Arabian, was about the best. The cross appears in the pedigree of some good race-horses: Trumpetta, by Trumpator, son of Conductor, by Matchem dam by Highflyer, son of Herod, grandam by Eclipse; she was the dam of Trumpator, by Dragon; a filly, by Dare Devil, from which many good race-horses descended; and a filly, by Hickory, son of imp. Whip, by Saltram, which was the dam of Fertility, by Boxer, son of imp. Expedition, by Pegasus, by Eclipse; Trumpator by Sir Solomon, and others. He also imported Janette, by Mercury, son of Eclipse, dam by Highflyer; Favorite, by Volunteer, son of Eclipse, dam by Matchem; she was dam of Volunteer, by imp. Bedford, by Hackabout, by Escape, son of Highflyer, dam sister to Syphon, by Tandem, by Squire, by Bartlett's Childers; she was also the dam of Maid of All Work, by Stirling, son of Volunteer, and Harriet, by Highflyer; Miss Eagle, by Spread Eagle, and Cowslip, by Bedford; Gausteria, by Balloon, son of Highflyer, dam by Marske, sire of Eclipse, by

Squirt; she was dam of Cremona, by Spread Eagle, Miss Marake and Rosa Munda, by Bedford. He also imported Alexandria, by Alexander, son of Ellipse, dam by Woodpecker, son of Herod; she was the dam of Rosalba, by Spread Eagle, Megg of Wapping, by Bedford, and Poll of Plymouth, by Archduke. The families are extinct.—*The Turf, Field, and Farm.*

A COMPARISON OF THE COST OF LABOUR, AND THE PRICE OF PROVISIONS, BETWEEN 1834 AND 1884.

A VERY carefully-prepared paper on the economic and social conditions of Manchester and the surrounding districts, as they exist now, and as they were fifty years ago, was read in November last, before the Manchester Statistical Society, by its President, Mr. Robert Montgomery. Although the statistics refer specially to Manchester and the neighbourhood, they are applicable to all parts of Great Britain where manufacturing is carried on, and even to many agricultural countries.

As a result of careful investigation, Mr. Montgomery shows that the increase in the wages during the fifty years averages 40 per cent—that is to say, where 10s. was paid fifty years ago, 14s. is now paid; and if we take into account the lessened cost of the principal necessities of life (for whilst some articles of food, such as meat, milk, butter, potatoes, and cheese have advanced from 10 to about 50 per cent, others have fallen to a much greater degree), which averages about 18 per cent, this 14s. is equivalent to 16s. 6d.

We all know that wages are much higher now, and the cost of many articles of food is much less; but it is only by a reference to statistics such as Mr. Montgomery furnishes, that we fully realize their extent.

The following gives the increase in wages in the respective trade:—

Trades.	Percentage of increase.
Spinning	63
Weaving	43
Drying	16
Calico printing	46
Calendering	47
Bleaching	32
Mechanical engineering	18
Glass-making	40
Macclesfield Silk trade	37
Building trades	46
Tailoring	53
Police	48

Average per cent of increase for all trades, 1834 to 1884, 40 7/12.

The following prices of the different articles of food are taken from the books of the Manchester Infirmary for 1834 and 1884:—

	Prices.		Percentage.	
	1833-34	1883-84	Increase.	Decrease.
	s. d.	s. d.		
Flour, per sack ...	35 0*	38 0	—	8
Meat, per lb. ...	0 7½	0 5	48	—
Milk, per doz. quarts, ...	2 6	2 2	15	—
Butter, per lb. ...	1 2	0 10	40	—
Cheese, per cwt. ...	66 4	60 0	11	—
Coffee, per lb. ...	1 0	1 10	—	48
Tea, per lb. ...	1 9½	5 0	—	65
Potatoes, per load ...	8 8½	7 6	29	—
Coal, per ton ...	9 0½	11 8	—	23
Soap, per cwt. ...	80 0*	50 6	—	40
Sugar, per cwt. ...	26 0	72 0	—	64
Glass, 1,000ft. ...	2 8½	10 8	—	74

Rent is not brought into the account—but respecting this, Mr. Montgomery says: "Rent is probably a larger item in the expenditure of a householder living in a town than it was in 1834. The price of land affects the rent, and has increased manifold; but in this matter, as in those of food and clothing, our standard of comfort is higher, and if we pay more rent, we get a better house."

Mr. Montgomery, after commenting upon the large sums, out of savings of the working classes, which are invested in Co-operative Stores and Limited Companies, concludes his instructive paper as follows:—

The inhabitants of Manchester are now enjoying these advantages of communal life, most of which were wanting 50 years ago, literally without cost, for in the year 1834 the local rates in the township were 4s. 11d. in the pound, and in this year they are only 4s. 4d. In knowledge, manners, and even in morals there is improvement to note in the past fifty years. Education is more diffused, and assuredly more thorough. In economic conditions the advantage has been with the workman rather than the master, and this will remain with him if he will save his money and employ his political influence and power of combination in fostering the growth of capital and applying it to productive uses. In the social progress of half-a-century, all classes have shared; the poor most of all. And in a fuller civic life, wider corporate action and a more fruitful use of the nation's power, it may be anticipated that the working classes will enjoy a still more conspicuous advantage.—*The Sugar-cane.*

* Estimated

WHAT IS THIS DISEASE THAT IS COMING UPON US?

LIKE a thief at night it steals in upon us unawares. Many persons have pains about the chest and sides, and sometimes in the back. They feel dull and sleepy; the mouth has a bad taste, especially in the morning. A sort of sticky slime collects about the teeth. The appetite is poor. There is a feeling like a heavy load on the stomach; sometimes a faint all-gone sensation at the pit of the stomach which food does not satisfy. The eyes are sunken, the hands and feet become cold and feel clammy. After a while a cough sets in at first dry, but after a few months it is attended with a greenish coloured expectoration. The afflicted one feels tired all the while, and sleep does not seem to afford any rest. After a time he becomes nervous, irritable, and gloomy, and has evil forebodings. There is a giddiness, a sort of whirling sensation in the head when rising up suddenly. The bowels become costive; the skin is dry and hot at times; the blood becomes thick and stagnant: the whites of the eyes become tinged with yellow, the urine is scanty and high-coloured, depositing a sediment after standing. There is frequently a spitting up of the food, sometimes with a sour taste, and sometimes with a sweetish taste; this is frequently attended with palpitation of the heart; the vision becomes impaired with spots before the eyes; there is a feeling of great prostration and weakness. All of these symptoms are in turn present. It is thought that nearly one-third of our population has this disease in some of its varied forms. It has been found that medical men have mistaken the nature of this disease. Some have treated it for a liver complaint, others for kidney disease, etc., etc., but none of the various kinds of treatment have been attended with success, because the remedy should be such as to act harmoniously upon each one of the organs, and upon the stomach as well: for in Dyspepsia (for this is really what the disease is) all these organs partake of this disease, and require a remedy that will act upon all at the same time. Seigel's Curative Syrup acts like a charm in this class of complaints, giving almost immediate relief. The following letters from chemists of standing in the community where they live show in what estimation the article is held:—

John Archer, Harthill, near Sheffield:—I can confidently recommend it to all who may be suffering from liver or stomach complaints, having the testimony of my customers, who have derived great benefit from the Syrup and Pills. The sale is increasing wonderfully.

Geo. A. Webb, 141, York-street, Belfast:—I have sold a large quantity, and the parties have testified to its being what you represent it.

J. S. Metcalfe, 55, Highgate, Kendal:—I have always great pleasure in recommending the Curative Syrup, for I have never known a case in which it has not relieved or cured, and I have sold many gross.

Robt. G. Gould, 17, High-street, Andover:—I have always taken a great interest in your medicines, and I have recommended them, as I have found numerous cases of cure from their use.

Thomas Chapman, West Auckland:—I find that the trade steadily increases. I sell more of your medicines than any other kind.

N. Darroll, Clun, Salop:—All who buy it are pleased, and recommend it.

Jon. Balkwill, A.P.S., Kingsbridge:—The public seem to appreciate their great value.

A. Armstrong, Market-street, Dalton-in-Furness:—It is needless for me to say that your valuable medicines have great sale in this district—greater than any other I know of, giving great satisfaction.

Robt. Laine, Melksham:—I can well recommend the Curative Syrup from having proved its efficacy for indigestion myself.

Frickheim, Arbroath, Forfarshire, Sept. 23, 1862.

Dear Sir,—Last year I sent you a letter recommending Mother Seigel's Syrup. I have very much pleasure in still bearing testimony to the very satisfactory results of the famed Syrup and Pills. Most patent medicines die out with me, but Mother Seigel has had a steady sale ever since I commenced, and is still in as great demand as when I first began to sell the medicine. The cures which have come under my notice are chiefly those of liver complaint and general debility.

A certain minister in my neighbourhood says it is the only thing which has benefited him, and restored him to his normal condition of health after being unable to preach for a considerable length of time. I could mention also a great many other cases, but space would not allow. A near friend of mine, who is very much addicted to costiveness or constipation, finds that Mother Seigel's Pills are the only pills which suit his complaint. All other pills cause a reaction which is very annoying. Mother Seigel's Pills do not leave a bad after-effect. I have much pleasure in commending again to suffering humanity Mother Seigel's medicines, which are no sham. If this letter is of any service, you can publish it.

Yours very truly,

(Signed) WILLIAM S. GLASS, Chemist.

A. J. WHITE, Esq.

15th August, 1883.

Dear Sir,—I write to tell you that Mr. Henry Hillier, of Yatesbury, Wilts, informs me that he suffered from a severe form of indigestion for upwards of four years, and took no end of doctor's medicine without the slightest benefit, and declares Mother Seigel's Syrup which he got from me has saved his life.

Yours truly,

Mr. WHITE.

THE INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA.—SATURDAY, MARCH 28, 1885.

[No. 13.]

Crop and Weather Report.

[FOR THE WEEK ENDING THE 18TH MARCH 1885.]

General Remarks.—The rainfall of the past week has been confined to a few districts in Bengal, Assam, to one or two places in British Burmah and Madras, and to Rawul Pindie and Sumbulpore in the Punjab and Central Provinces, respectively.

The standing crops are generally fair in the Madras Presidency, but the harvest yield is below the average. The *rabi* harvest is nearly complete in most districts of the Bombay Presidency. It is in progress in other parts of the Presidency, as also in Bengal, the North-Western Provinces and Oudh, Central Provinces, and the Berars, and gives promise of a good outturn.

In Mysore scarcity of water is becoming more felt, while the outlook for cattle and the prospects of the rice harvest are unfavourable. In Assam, crop prospects are generally good; ploughing operations still continue. In the Central India and Rajpootana States agricultural prospects are favourable; the *rabi* is being harvested in Harowtee and Jeypore.

Cholera and smallpox are reported from most provinces, otherwise the public health is generally good.

Prices are rising slightly in parts of the Punjab, elsewhere they remain generally steady.

Madras.—General prospects fair, except in parts of Bellary and Anantapore.

Bombay.—*Rabi* harvest nearly completed in most districts of the Deccan and in Belgaum; in progress in other districts; standing crops injured by rust, blight, and drought in parts of Sindh, and by mildew in parts of Nasik; cotton slightly injured by cloudy weather in parts of Broach; scarcity of fodder and drinking water continues in parts of Dharwar and Belgaum; fever and small-pox in parts of 11, and cholera and cattle-disease in parts of 9 districts.

Bengal.—Slight rain fell in a few districts; ploughing operations for next season's crops are generally going on; harvesting of *rabi* crops still continues; *boro* paddy, *cheena*, and *kuon* are thriving; pressing of sugarcane is going on with good outturn; price of rice is stationary; cholera and small-pox prevail in some districts, otherwise public health is good.

N.W. Provinces and Oudh.—Weather seasonable; harvesting in progress; markets well supplied; general health good.

Punjab.—Slight rain in Rawul Pindie district; health and prospects good, except in Lahore district, where wheat crops attacked by *kunji* (rust) and suffering for want of rain; prices slightly rising in Delhi, Mooltan, Rawul Pindie, and Peshawur, and stationary elsewhere.

Central Provinces.—Weather continues cloudy; *rabi* harvesting almost concluded in southern districts, still in progress in northern districts; cholera has broken out in Chuttigarh, and cases of it have occurred in Nimar district.

British Burmah.—Small-pox prevalent in several districts, but for the most part trifling; a little sporadic cholera also, otherwise public health good; cattle generally healthy; weather very hot.

Assam.—Weather warm in the day, but cool at night; no crops on the ground; common rice 17 11/16 seers per rupee; one death from small-pox reported from Lbakhipore; general health good.

Mysore and Coorg.—Standing crops reported withering in Bangalore and Kolar, but the area concerned is not large; scarcity of water generally becoming more felt; prospects for cattle and rice harvest unfavourable; public health fair; prices rising.

Berars and Hyderabad.—*Rabi* crops continue to be reaped; *tabi* crops prospering; general health good; prices—wheat 14½, coarse rice 11, white *juar* 16, yellow *juar* 22, and *tur* 19½ seers per *hali* sicca rupee; weather clear and warm; prospects favourable.

Central India States.—Health and prospects good. Weather variable; opium and other crops good.

Rajpootana.—Heat increasing; grain being harvested; some measles in Tonk; otherwise, health good.

Letters to the Editor.

A STEAM THRESHER FOR INDIA.

TO THE EDITOR OF THE TIMES OF INDIA.

SIR,—I read to-day with much pleasure the succinct and correct account given by your correspondent of the trial with the steam thresher at Niphad. I hope that your readers will be glad to get more detail.

I saw the steam thresher at the Calcutta Exhibition. It is the work of Messrs. Marshall, Sons & Co., of Gainsborough, whose agents in India are Messrs. Balmer, Lawrie & Co., of Calcutta. After careful enquiry into the cost of cleaning wheat under the native system, I pressed on the Calcutta firm the advisability of experimental working with steam. The question was incidentally raised whether machines worked by hand or bullock power would not be more suited to the conditions of the country. I thought not. The native craftsmen cannot yet be trusted to repair machinery, and the jerky uneven work of the bullocks would be fatal to the success of the delicate operation of threshing wheat. I offered the use of bullock power; but the offer was wisely declined. Messrs. Marshall & Co. have sent out a trained engineer, who has introduced the machine into parts of Russia, Italy, Spain, and elsewhere, while Mr. W. Gallon, C. E., has been deputed by the Calcutta firm. It is evident that whether the present venture is successful or not, it will show what special modifications are required to adapt the thresher to local requirements.

The engine is a small four H. P. one. The thresher separates the corn into *firsts*, *seconds*, and *thirds*. A fourth bag catches any unfinished grain which escapes the riddles, and the contents of this bag are passed a second time through the machine. The straw is separated into long straw, short straw, and chaff. This separation is not necessary in this country as far as the straw is concerned, but is unobjectionable. The separation of the good grain from the bad and from chaff and earth is of the first importance, seeing that a clean sample appears to be almost the only thing wanting to secure a certain market in Europe for Indian wheat and a price apportioned to its intrinsic value. The experiment showed that the machine can easily turn out 8 tons (216 imperial maunds) of good wheat (*firsts*) in a working day of eight hours. In order to calculate the proportion of the various products, a careful trial was made with 50 sheaves. The results were—

CORN.

Firsts ...	92.2 per cent.	Absolutely pure grain.
Seconds ...	4.9 per cent.	Small and broken grains.
Thirds9 per cent.	The seconds contained no chaff or dirt.
Tailings...	.8 per cent.	Usually reaped through the riddles.
Grain in Straw ...	1.7.	

STRAW.

Long Straw ...	80 per cent.
Short " ...	40 per cent.
Chaff " ...	30 per cent.

The *firsts* at the beginning showed a very small percentage of broken grains, but this was much reduced by alteration of the drum, which had been tightened in order if possible to bruise the straw. The short straw and chaff were very carefully dressed over again by hand, but were found to include no grain. The long straw alone showed the percentage given; but this does not mean a loss to the owner of the grain, as will be shown. The straw was not reduced to "bhuss" as when the wheat is trodden out by oxen. When this fact became apparent to the owner, his alarm began. He insisted on having the engine stopped. An enquiry was made. It was clear that the straw was not, as turned out, fit for cattle. The wheat awns remained unbroken, the chaff and long straw were hard and stiff. This was a rational objection. But most of the ryots

irrationally asserted that it would be impossible to make it fit for fodder, urging that it would not be broken up by the oxen, without the help of the grain. To settle this point, the straw and chaff from 50 sheaves were trodden out before their eyes, and in half-an-hour were certified by competent agriculturists to be fit for fodder. I may state that it took three hours to tread out 50 sheaves in order to separate all the grain. The defect is easily remedied by the addition of a straw bruiser; which, however, cannot be brought out till next year. The next objection to the machine was that some of the grain goes over with the straw. As I have said, this is only with the long straw. The straw bruiser will again remedy this defect, for it is furnished with an extra set of riddles, which catch all the grain separated from the long straw. But even without the straw bruiser no loss need occur. When the straw is trodden out, the grain is all collected, and, as I have said, the time required to trample the straw is very small in comparison with that needed to beat out the grain. So far the objections made were rational; but when the bags which caught the good and the poor grains were shown, the ryot exclaimed, "Why should I suffer this loss? I can sell good and bad together." At the same time, the village Bunniah said, "This is good for the trade." I may here parenthetically remark that these expressions are pregnant with deep meaning. My interpretation is that, under present conditions, the ryot does not reap the benefit he should reap from care in preparing his produce. In his primitive method he cannot altogether keep out field earth and pebbles worked up from the threshing floor into his grain. The wheat merchants are compelled to recognize the fact, and accept tenders with a percentage of impurities. Even if this percentage is fixed as low as is possible, dishonest middlemen only clean down what they buy sufficiently to pass muster, and when they are lucky enough to receive a sample, containing impurities below the allowance, they say, "Why should I suffer loss? I would be a fool not to bring up the impurities, and raise the weight if I can make the wheat pass muster." And so the clean produce of the threshing machine, which is so necessary to raise the Indian wheat trade to its just position, will, if middlemen are not ousted in the matter, only put unjust gain into their pockets. It is for the Chamber of Commerce to assist in this crisis.

It must, however, be noticed that even if the ryot does not get a fair price for his produce, he cannot suffer loss by the machine. He pays a share of his grain as *ba'uta* to the village carpenter, blacksmith, and mhar, and he eats a certain quantity of wheat on feast days. The 8 per cent of produce which is not classed as good grain will not be more than is required for these purposes. True, he is no longer able to sell dirt as wheat, but I confidently hope that even under present conditions, the price he will receive for clean wheat will more than compensate him. The village bunniah even said that he would give Rs. 80 per candy for the wheat, whereas the market price was Rs. 70. I have sent samples to the Chamber of Commerce for opinion.

The next point is the charge which the owners of the machine will exact. The experiment, as may be inferred from the facts noticed, was carried out in the face of much opposition, yet showed that a charge of one anna per maund (of 82 lbs.) will pay the enterprising firm, and this, as based on the outturn, is of itself only, the machine bearing all the cost of fuel, water and labour, save and except the carting of the wheat. Now I have satisfied myself that the treading out process costs the ryot, at the very lowest estimate, three annas per maund, when he has a strong wind to winnow with, and when his cattle are not absolutely required for other work. Dr. Fairbank, whom your readers know, and who was present at the trial, thinks my estimates too low, but I advisedly took care not to run the risk of fixing too high a figure when corresponding with Messrs. Balmer, Lawrie & Co. In many places wheat straw is of little value as fodder. Wheat straw is the least nutritive of the straw of all cereals. It is, unfortunately for the present experiment, almost the only fodder in Niphad, where wheat straw can be used as fuel (the machine is specially adapted to using it; as such), the cost per maund is reduced to 8 pies. Not only is there a direct saving in cost of threshing, but there is as direct a saving in the fact that re-winnowing in Bombay is rendered totally superfluous. The Chamber of Commerce have estimated this cost at 3s. 2p. per maund. I believe a few other minor expenses are included in this figure. But there are other and more important results to be secured. In enumerating these, I will conclude what I have to say at present—

1. The cost of carriage is reduced, because dirt and other impurities are eliminated.

2. The wheat can be put into the market as new wheat almost as soon as reaping is completed. New wheat must fetch a higher price than wheat kept for a year in pits.

3. The loss which must result from pitting or otherwise preserving wheat is avoided.

4. The loss from wastage in transit and breaking of bulk is saved.

5. The ryots' cattle are freed for field work, which, under present conditions, is neglected, but which would repay the farmer many fold.

6. The profits of middlemen are reduced, and with proper arrangements are capable of total extinction. This means profit to the grower, which now he does not dream of, and cheaper wheat in the foreign market, which can undersell the wheat from other countries, now gaining in the competition, owing to the apathy and ignorance of India. May I not add that if the owners of steam threshing machinery can either directly or indirectly ship the wheat direct from the machine to England, they will soon secure a special quotation in the home markets? They have the choice of the crops of the year. They can refuse to thresh a poor one, and can confine themselves to the best which the season can produce.

It cannot be yet expected that village communities or native zemindars will at once buy this steam machinery. But to my mind Messrs. Marshall, Sons & Co. have wisely recognized this fact, and will reap profit from their foresight. Albeit the ryots of Niphad asked me, "Why do you bring this machine? Why disturb this calm current of our lives?" I verily believe that they think I have a pecuniary interest in the concern. Is there not encouragement in the success of steam ginning in cotton? Could it have been anticipated that ryots would have carted the seed cotton twenty or thirty miles to the gin and taken the seed back? It is a fact even now that ryots will cart their wheat even longer distances to secure a slightly higher price for wheat—a difference which seems absurdly small when the cost of cartage is estimated.

I am about to meet the machine at Puntamba in the Nizam's district, and, as noticed by your correspondent, the chief of Vinchur has bespoken it from the 2nd instant at Usalgaon. The machine has a special drum to adapt it to threshing rice, and if I err not, it will be known throughout the length and breadth of the Presidency, where it has made its first appearance.—I am, &c.

E. C. OZANNE,
Director of Agriculture.

Poona, March 16.

Editorial Notes.

WE are glad to learn that the Madras Government have awarded a gold medal to M. R. Ry. C. Kistnaswami Mudaliar of Shiyali, in appreciation of the interest he takes in the improvement of the agriculture of Southern India. Mr. Kistnaswami holds extensive estates in the Tanjore district, wherein he has introduced improved systems of agriculture, and at Shiyali he has opened a workshop where he makes improved ploughs of the pattern of Massey's, and sells them at a much easier price than that of the originals. Southern India—especially Madras Presidency—must indeed be proud of possessing such excellent agriculturists as Messrs. Kistnaswami Sabapathi Mudaliar of Bellary, Bashinkarnu Naidu of Coimbatore, and Rangiah Naidu and Dhankoti Raju of Madras. The Government, by its recognition of the services of such gentlemen, gives indeed a healthy impetus to the progress of agriculture, which is, in fact, the wealth, nay the all, of Southern India.

THE report on the prospects of the wheat crop in the Central Provinces, for the month of February is as follows: "Returns of actual area under wheat have only been received from six districts, and they show that the contraction in area has been in some cases rather over-estimated; thus the deficiency of 32 per cent in Wardha has been reduced to 21 per cent, and that of 10 per cent in Damoh to 8 per cent. It is however quite impossible to make a precise forecast of outturn, and all that can be indicated with certainty is that the crop is an excellent one, and the excess of its outturn over the normal will more than compensate for any contraction in area. The produce of fields harvested experimentally in the Raipore district has given grounds for an all-round estimate of 13 maunds per acre for one of the principal wheat-producing tracts in the Provinces. Wheat is now selling in the Raipore market at one maund per rupee. Exports from the Provinces still continue at the rate

of about a lakh and a half maunds per week, and the total amount exported up to date since October last is not less than 3,300,000 maunds."

.

A CORRESPONDENT writing from Niphar to a Bombay contemporary says:—"To-day was a remarkable day in the agricultural history of the Deccan generally, and the Nassick district in particular. The strong impetus that of late has been given to the wheat trade of India has induced the district officers and the Bombay Chamber of Commerce to take more than a passing interest in this important branch of our trade. Several efforts have recently been made to explain to the cultivators the paramount necessity of keeping their wheat free from dirt and chaff and grains of different varieties. Some of them have even afforded good seed selected by the Chamber of Commerce. The upshot of all these endeavours has been the importation of a thrashing and winnowing machine from Calcutta to this place, which is situated on the G. I. P. Railway between Nassick and Munmar. The working of this machine was shown to a number of agriculturists in the presence of Mr. Woodward, the Collector of Nassick, Mr. Ozanne, the Director of Agriculture, and several European and native district officers. The machine was worked by a steam engine by two European experts. Though the experiment did not quite fulfil the expectations of the kumbis, who always look upon an innovation with great distrust, the result taken, as a whole, was not discouraging. The machine worked with wonderful rapidity, and separated grain from husk and stalk so quickly that the natives who were present on the occasion were astonished with what was accomplished. Five gunny-bags were attached to the machine. All of them received grain that was being thrashed down in varying quantity and quality. The first bag received the largest and the best cleaned quantity, the second proportionately less than the first, both in quantity and quality, and so on. The wheat in the first bag was without the least dirt or chaff, and was such grain as would command very high price in England. The cultivators had, however, objections to the machine, the chief of which were that grain broke down to some extent, and that straw was not powdered down so as to be of use to them as fodder for cattle. Both these objections are remediable. In the case of the first objection there were 13 bags of the first quality to only one of broken wheat mixed with chaff. The experts in charge of the machine assured the people that this defect can be remedied. Considering the large proportion in which good wheat free from dirt and chaff was obtained, the machine cannot be considered a failure, because, even supposing that the drawback complained of cannot be overcome, the price that good wheat will fetch in the market will more than compensate the loss that may be sustained in broken grain. Besides, the work is done so quickly that a large quantity of new wheat which is always in greater demand, can be exported during the same season in which the crop was reaped. The other objection concerning straw can be met by making bullocks tread it as the farmers do at present. The kumbis, of course, shrugged their shoulders at all this. But there were enlightened native gentlemen present—the Vinchurkar and others, who have offered to give a fair trial to the machine on their estates. This spirit of enterprise is indeed creditable to them, and there is no doubt that their example will be eagerly followed by others at a time like the present when the price of wheat is rising, as the machine will give them an advantage over the orthodox system of slowly thrashing wheat by means of bullocks. As this is the first attempt of the kind on this side of India, it deserves every encouragement at the hands of those who have at their heart the welfare of the cultivators and the wheat trade of India."

.

The following report is furnished regarding the wheat crop of 1884 in the Rajpootana States (the figures are approximate only):—"The total acreage of wheat grown during 1884 in Rajpootana, exclusive of the States of Jaisalmer and Dungarpore, amount to 2,224,784 acres, and the total outturn to 14,482,637 maunds, giving an average yield per acre of 6.50 maunds."

From a review of the Agricultural Department in the Madras Presidency, we find that Mr. Mills conducted a series of experiments in preventive inoculation for anthrax, according to M. Pasteur's method. The results so far are satisfactory, and in Mr. Mills's opinion establish definitely the following conclusions:—

- (1) That the anthracine can be imported from Paris with safety.
- (2) That it readily becomes virulent if the tubes are exposed to tropical heat for any time.
- (3) That the tubes must be kept in an ice chamber.
- (4) That all animals can be with safety inoculated.
- (5) That the inoculations can only be conducted by a specially trained person.
- (6) That animals so inoculated enjoy perfect immunity, but for how long has not as yet been settled.
- (7) That the anthracine is a highly dangerous fluid in the hands of any one ignorant of its properties.

.

THE experiments conducted by Mr. Mills for the denaturalization of salt so as to make it available for agriculture and cattle without detriment to the public revenue were failures, and the late Chemical Examiner, Dr. Rogers, gave it as his opinion that the problem was insoluble by chemical or mechanical means. The real solution of it will probably be found in the increase of facilities for transport and reduced prices. Mr. Mills notices a new drug, "nitrite of sodium," which, from experiments made by him, promises to be of great therapeutic value in the treatment of *paraplegia*. It has been tried successfully in the treatment of neuralgia and allied diseases of the human subject. The exact quantity of carbolic acid that could be administered to a buffalo has never been determined, but Mr. Mills's experience in the year under review shows that as much as an ounce ~~can be safely given~~ if it be properly diluted. The smallest dose of this drug is a dangerous and irritant poison, if administered pure and undiluted.

.

MR. MILLS's experiments with aconite have led him to the conclusion that the doses laid down in the various pharmacopœias are erroneous and misleading. The official dose is put at from 30 to 50 minims for a horse and from 40 to 80 minims for cattle. In Mr. Mills's experience 3 oz. were administered to a pony within a few hours without the slightest effect. A further experiment went to show that the *herbivora* can take fifty times the quantity of this drug that the *omnivora* can. Mr. Mills speaks again very highly of the antiseptic value of boroglyceride, which he regards as almost a specific for unhealthy ulcers. Its price, however, Rs. 5 a pound, he considers to be prohibitive of its general use. The *Rudrakshan* seed, three hundred doses of which were sent out in 1882-83, did not prove of much value in the treatment of rinderpest, for which it was supposed to be a specific. Experiments were conducted, and are, under the orders of Government, being continued in animal cremation. A pamphlet on the subject written by Mr. Mills was widely distributed. Mr. Mills paid 134 visits during the year to the various slaughter houses in Madras. These visits which were entirely voluntary have, beyond doubt, resulted in good. It is satisfactory to know that the sanitary condition of the yards was generally good. Mr. Mills's efforts have had the effect of almost entirely stopping the slaughter of gravid animals, which was formerly frequent. His endeavours to prevent the spread of parvotic diseases by taking measures for the exclusion of dogs and the destruction at the slaughter-house of the cysts of the tape and other intestinal worms deserve all praise. All that is wanted is a plenty of boiling water. The butchers appear to have readily seconded Mr. Mills's efforts.

.

THE statistics for that Presidency show that rinderpest and anthrax were the two most prevalent diseases during the year. The deaths from all diseases were 15,108, of which 7,821 were due to rinderpest, and 5,871 to anthrax. The latter was, as usual, more fatal of the two diseases, the deaths in the year being 64 per cent of the attacks; in rinderpest 46 per cent of the animals attacked, died. Both diseases prevailed in every district of the Presidency, but not to the same extent nor so fatally

as in last year. The mortality from all causes was for the corresponding period of this year rather more than half that during the seven months embraced by the figures of last year, and the percentage of deaths to attacks was only 41.94 as against the 59.36 of 1882-83. It was found necessary to enforce the provisions of the Madras Cattle Disease Act II, of 1866 in the districts of Vizagapatam and Chingleput. Further enquiry has led Mr. Mills to conclude that his last year's estimate of the value of cattle, &c., was too low; and now, taking Rs. 25 as the average value per head of cattle and buffaloes, and Rs. 2.12-0 for sheep and goats, and deducting one-fifth from the total number on account of young and undersized animals, he estimates the value of the cattle lost from disease during the year at Rs. 2,68,080. In addition to their ordinary duties of inspection, advice and treatment, the District Inspectors attend all local cattle fairs and make reports on the cattle exposed there for sale. Some of these reports, Mr. Mills says, are excellent.

THE following report has been received regarding the prospects of the wheat crop in the Baroda State :—" Probable area in ordinary years, 69,982 acres; probable gross production when the crop is a 12-anna one, 82,900,555 lbs.; estimated area in 1883-84, 111,578 acres; estimate gross production on crores, 4,597,700 lbs."

THE question of storing water in tanks with a view to its utilization for irrigational and other purposes in seasons of drought, is one of some importance, and our farmers, cultivators, and the people generally would hail with satisfaction any means by which a good supply of water could be kept in tanks, with the least possible waste of the precious fluid by evaporation and other causes. A meeting of the New South Wales Royal Commission on Water Conservation was recently held, and some valuable suggestions were thrown out by the Inspector of public tanks and wells on the most useful methods of storing water in tanks and dams. It was pointed out by the Inspector that the expediency of storing water in deep excavations instead of in shallow ones, was of such importance that there was scarcely any need to go into the causes. It was however pointed out that the ratio of evaporation in shallow excavations increases in a compound ratio, and it was therefore recommended that tanks should be deepened, instead of having the evaporating surface increased by sloping the banks—a plan that is generally adopted in the excavation of tanks.

It was also suggested that water-lilies (a plant that is common enough in India) should be planted in tanks and dams with the object of lessening as much as possible the loss by evaporation, if, as is supposed, the presence of these plants was likely to produce that effect. This is, however, a point which could easily be determined by careful observation.

It may be added, in this connection, that on English farms it is the practice to plant weeping-willows, alders and other water-loving trees closely around water-holes, with the object of keeping the water cool, and preventing the banks from being injured, leaving only one opening, and that paved with boulders, for the access of stock.

In the English climate, however, the question of water conservation, and the means of preventing waste by evaporation, are not of such moment; but here in India, they are a matter of vital importance. It may be remarked that the suggestion about planting trees round about tanks is one which must be received with caution, as it is pretty well known that plants absorb a good deal of moisture during the day through the pores of their leaves, and give off exhalations of vapour at night; so that any process which drew upon the tank for moisture would tend to reduce the water-supply. It is true that pools of water exist embedded in thick clumps of trees without any perceptible diminution of their contents; but this would only apply to situations where the sun did not penetrate at all. Lower Bengal teems with such pools; but it would be rare to find

them higher up in the N.-W. P., the Punjab, and particularly in the sandy wastes of Rajpootana and Sind. It is for consideration, however, whether the suggestion about deep excavations in preference to shallow ones would prove of sufficient practical value if their surfaces are wholly exposed to the rays of the sun. If by any means these deep excavations could be shaded over with some dead material instead of by planting trees around them, there would be every prospect of preventing loss by evaporation. Any way, these suggestions will doubtless commend themselves to all interested in the subject, with the view of calling forth further expressions of opinion on a matter of so much importance as the conservation of water.

THE Government of Madras have lately had under consideration the subject of water-supply in the event of their existing stock proving inadequate to the demand during the ensuing hot season. There are two tanks—the Koratur and Ambatur, and two lakes—the Red Hills and Chembrambaukum—upon which the city depends for its supply of water for drinking and irrigational purposes. We would therefore commend to the notice of the authorities these suggestions of the New South Wales Royal Commission on Water Conservation.

EVERY one interested in the expansion of the Australian trade with India, and especially in the export of stock to this country, will be glad to hear that Mr. Thompson of Sandridge has built a steamer named the *Ducophalus*, expressly for this purpose, and which, when the last mail left, was loading a cargo of horses, as well as cattle and sheep for our market. Mr. B. Gray, who was once upon a time a large exporter of horses to different parts of the world, was invited by the owner of the vessel to inspect it, and pronounce his opinion as to its suitability for the purpose. The following is the result of his inspection. He says :—" I found a steamer capable of carrying 350 horses, or a larger number of cattle, with some passenger accommodation. I had not the slightest idea that there was such a vessel afloat. Some 18 years ago I sent several shipments of horses to Colombo, also a few cattle and sheep to my friends, Messrs. Rudd Bros., of that port, and although I spared no expense in procuring the best ships and fitting them in the best manner, the losses on each shipment were a heavy drawback on the transaction. I think I am safe in saying that in nearly all shipments to India and Mauritius since that time, heavy losses have been incurred, of course materially interfering with the trade. I was much pleased, therefore, to find that in this steamer there is everything necessary to minimise these losses to an extent quite marvellous compared to the days I refer to. The space allotted between decks to each horse is 3ft. x 9ft., with 10ft. in height, and some 18ft. from head to head in the rows. The hatchways are from 20ft. to 24ft. long, 10ft. wide, and there are four of these, supplying a current of air equal to any requirement, while 50 horses can be placed on deck in equally comfortable quarters, for the gunwales are some 5ft. high, and these are supported by iron arches, over which an awning can be thrown, thus protecting in all weather, furled in fair weather. All the fittings are of the most substantial kind, the floors battened and filled with sand between, and these are cleaned every two days, making all comfortable. The food is supplied in movable mangers to which the men have easy access.

" QUITE a novel feature in our export of stock to India were a large number of dairy cows that are being sent up for the purpose of establishing a herd of these cattle in the hill countries, and it appears to me that it will be a most successful venture, for there can be no doubt of the superiority of such stock over the native breeds, both as milk and beef producers, and comfortably lodged as these are in this fine vessel, I feel sure they will be landed in as good condition as when shipped. There was also a small lot of sheep, but I fancy those selected, being cross-breeds, are not the animals suited to that climate; however, it will test the practicability of sending sheep to India; in fact, the whole shipment is one of great import to Australia, and such an enterprise as building this vessel lays all stockbreeders under a great obligation to her owner, and I see no reason why

live stock could not be carried in such steamers to the English market, especially from northern ports, where such large tracts of country are being stocked. The facilities for putting stock on board this vessel are so great that a whole cargo can be walked safely on board in some three or four hours, and transhipped with equal facility. The lines on which she is built strike the most unnautical to be such as would ensure speed and safety, and Captain Currie told me her record was 12 knots an hour. No doubt, a good deal of the success of the trips of this boat is due to the sterling character of her commander, who strikes one at first sight as a thoroughly practical seaman, with his weather eye always open. The horses which form the chief cargo this trip, are the property of Mr. Learmouth, well-known in the Indian trade, and I think Colonel Williams must be more critical than he is if he rejects any of those I saw waiting to go on board. They were also in splendid condition, speaking volumes for the pasturage they had come off, and I shall be much disappointed if this does not turn out one of the most successful ventures of stock that Australia has shipped; and have only to add that my description falls short of what might be said of so interesting a subject to stock owners."

.

In our last issue, want of space prevented our taking more than a cursory view of the report on the forest administration of Coorg. We shall now refer to some interesting details connected with the subject. We are told that last year was a trying one. Owing to the long dry season, lasting from November till 20th April, numerous fires occurred which however were usually put out before much was burnt. There is no doubt that most of these were put in intentionally, so easy a thing to do that it is not surprising that no one was found out. To light a fire in the jungle is the work of an instant, and, before the fire is discovered, the person may be miles away from the place. The only thing to do, is to increase the number of guards, encourage vigilance by suitable rewards in case of success, and make smaller forester's charges. With the available means, every effort was made this year to ensure success. The two forests in which the worst fires occurred were Dubare and Hatgatnad. They are always difficult forests to protect: Dubare, because the labor is very uncertain and independent, and because of the coolies' habit of absenting themselves on bazaar's day and not returning for two or three days. It was during one of these periods that the big fire occurred. Hatgatnad was most unfortunate in the forester getting seriously ill in the very nick of time. The ranger took up the work until another man could be brought up. This man being a stranger to the forest, the result was unfortunate as it was natural to expect. In the other forests the trees, although numerous, were not extensive. Much has been learnt by the year's experience, and no doubt a better success will be attained in future years. But the Coorg forests, overrun as they have always been by kurambars, yoravars and Coorg ryots after game, are certainly not easy to protect. The results however compare well with those of 1882, although the season was almost as bad as regards the duration of the dry weather. The area successfully protected was 113,665 acres out of 123,292 acres attempted, or 92.2 per cent. The cost of protection was Rs. 2,029 or Rs. 10-8-0 per square mile, against Rs. 2,446 and Rs. 13 per square mile last year. This saving of Rs. 2-8-0 per square mile is the result of better supervision and measurement of work, and is thus satisfactory.

.

In the matter of artificial reproduction, the year was a good one for planting, and much good work was done. The teak plantations were enlarged by 126 acres and the sandal plantations by 107 acres. The planted area is now—

Teak	429 acres.
Sandal	278 "
Fuel	85 "

To show the value of these areas for the sandal alone, it is shown in para. 63 that about 20 trees go to a ton, and as they do not require much room, it is thought that at least 400 trees per acre will remain for the final crop. Putting the price per ton very low at Rs. 300, the value of the crop will be Rs. 6,000 per

acre. From all that is known of sandal, 40 years seems to be the time for it to come to maturity. Discounting then at 4 per cent, the present value of these plantations is Rs. 1,300 or Rs. 3,31,400 for the 278 acres. The cost up to date has, it is true, been heavy, because experience has to be bought, but even that is a mere nothing when compared with the value. The total expenditure has been Rs. 22,900; this accumulated at compound interest at 4 per cent for 40 years will amount to Rs. 1,09,942, to set off against the magnificent total of Rs. 16,68,000. Previously planted areas were well tended. A few small new clearings have been made for sandal aggregating about 10 acres; also 3 small clearings for teak above ghat, and one large one below ghat at Kutampole aggregating 150 acres. At Kutampole the clearing on being surveyed turned out only 37 acres, instead of 60 as was estimated. This arose from the deceptive nature of the land, and to avoid any mistake of the kind this year, the new clearing has been surveyed before planting and turns out about 140 acres. Mr. Tod, the contractor, has received the contract rate for planting 60 acres, and thus owes the department a considerable amount, namely, the contract rate for planting 23 acres, which will have to be deducted from the amount he has to receive during the year for planting the new clearing.

.

The new plantings at Kutampole, both those of 1882 and 1883, have been very successful, and the growth of the plants is remarkable, compared with other plantations in Coorg. In December last, the plants being then 19 months old in the 1882 clearing and 7 months old in that of 1883, the former averaged 11 ft. in height and the latter about 3. Since that, however, owing to the long dry weather, there has been hardly any growth. The work done at Karmad was principally clearing the weeds in the lines, cutting creepers, girdling old jungle trees of which there are still a good many left, although the work has been going on for a good many years at intervals. If it had not been for them, something would have been obtained already from thinnings, but the latter have been as yet too insignificant to mention. By clear felling and careful weeding from the first, the new plantations will be made to pay very much sooner than the old ones, which were planted partly under shade and allowed to get weedy directly after planting. A clearing of 30 acres was opened in Anekadu in North Coorg, and successfully planted by the forester at the rate of Rs. 43 per acre. It is hoped that this rate may be lowered for future clearings. Scraping was resorted to to get rid of the enormous stifling crop of grass which grows up as soon as jungle is cleared, and prevents all tree growth except that of the inferior fast growing kinds. This operation is expensive, but will be cheaper in the end than constant and what seem to be interminable weedings. Teak nurseries for the coming season's work are ample, and contain more plants than will be required for the plantations. What remains over will be put out in open spaces in the forest. The sandal plantations were fairly successful, and would have been more so, had it been possible to allow money. As it was, in North Coorg somewhat more land was got ready than was ordered, and it was necessary to stop some of the work. The areas left unstocked on this account are being now cleared, and will be planted up in the coming season. With the 278 acres now fully stocked, it will not be necessary to make large additions in future, and there will be a good deal of work to consolidate what is already planted.

.

In South Coorg, owing to a scarcity of seed very little was done to supply up the half-planted areas in Nalkere and Karmad, measuring in all some 15 acres. This was unfortunate as a year's growth was lost, and the same weeding had to be done as if the plants were really there. At Titimatti the forester did good work, and this is now one of the best sandal plantations in Coorg next to Gangavara. The average cost for new work was Rs. 49 the acre and for weeding and up-keep Rs. 15. It is probable that considerable expenditure will be incurred for some years on the up-keep of these, as it is noticed that even in the oldest parts (4 years old) a thick crop of grass still grows up, and if the grass is allowed to get any height, and partially cover the trees, the branches die back. The

growth of grass is however becoming much less thick, so that gradually the weeding expenses must diminish. In a few years it will be possible to allow a limited amount of grazing which will effectually keep down weeds. Some of the older planting might now be grazed over, but they are too small to make it worth while to fence them off from the younger bits. It is, however, better to lay out money on weeding and insure the future of these plantations so long as due economy is observed. This year's experience has shown that sandal grows better with lateral shade than alone. To get this lateral shade all jungle-tree stumps in the clearings are now allowed to keep their shoots, these being kept within bounds by judicious thinning.

.

THE report on the prospects of the wheat crop in the North-Western Provinces and Oudh for the month of February is as follows:—"Wheat area of United Provinces is 5,266,319 acres, which is greater than January area by 57,667 acres, and greater than normal area by 300,636 acres; taking normal at 100, the area now under wheat in the United Provinces is 105. Area under white wheat, 1,211,762 acres; under red wheat 2,003,643 acres; under mixed red and white wheat, 2,050,914 acres. The crop has suffered a good deal from rust caused by the cloudy weather and easterly winds following immediately upon the rain of the end of January, and prospects are not so good as in January. Taking 100 to denote full average, the condition of the crop is as follows:—56,264 acres stand at 100; 160,515 acres at 90; 1,346,124 acres at 81; 3,309,963 acres at 75; 93,453 acres at 60. The gross outturn of a full average crop would be 2,480,000 tons. The February estimate of the season's crop is 1,950,000 tons. Taking 100 to denote full average crop, season's crop thus stands at 80."

.

A SHORT time ago, Mr. Commissioner Loring, the head of the American Department of Agriculture, delivered an important address at the National Convention of Cattle-breeders, held at Chicago, with special reference to the cattle and dead-meat industries in the United States. The figures quoted by him show that the enumeration of the cows in all the States and territories gives 13,501,206, and that of other cattle gives us 29,046,101. The estimated value of the cows is \$423,486,649, and the estimated value of other cattle is \$683,229,051. The total amount of this species of property is \$1,106,715,703. The average value of the cows is \$31.37, and that of other cattle is \$23.52. New York has the largest number of cows used in the dairy (1,510,904), and Wyoming the smallest (4,533). New York has \$54,89,142 in cows, and \$33,084,771 in all other cattle. Wyoming has \$149,589 in cows, and \$23,446,550 in other cattle. The improvement of cattle by care and judicious breeding during the last three-quarters of a century, is made evident in a table giving full details on this point. In the New England States, the value of this improvement is 34 per cent; in New York, New Jersey, and Pennsylvania, 38 per cent; in the Western Central States it is \$125,575,324 on \$316,007,714; in the Cotton States, \$36,802,499 on \$106,629,757. In an investigation by the Bureau of Statistics of the Department, made last April, estimates of the number of high-grade cattle ranged from 5 per cent in New Mexico to 40 per cent in Ohio and Kentucky, and averaged 18 per cent, or 7,723,539 of a total of over 42,900,000 animals. An attempt was made to indicate approximately that portion of the present value of cattle represented by improvement in breeding since the introduction of improved herds—that is, of the present value of all cattle, how much is due to the efforts of breeders, and what would be the value of present stock if in size and quality of the unimproved natives. The average improvement is 35 per cent, and amounts to \$287,000,000. This would make the value of cattle, as unimproved natives, \$819,000,000, and the real value, as improved, 35 per cent more, or over \$1,106,000,000. To show the extent to which improvement, by superior blood, has been carried, attention is called to the large percentage of high-grade cattle now found in the States and territories. It is interesting to know how large this percentage is in States where agriculture is the leading business. While in some of the States the amount of high-grade and pure-bred cattle is only 8 or 9 per

cent, in Kentucky it is 40 per cent, in Ohio 40, in Indiana 33, Illinois 35, and Massachusetts 32 per cent. The total number of horned cattle west of the Mississippi River is estimated at 21,943,574, with a money value amounting to \$533,650,871 divided among the States and territories of that section. Arizona, with 216,057 horned cattle, valued at \$4,494,352, stands lowest on the list, while Texas represents the largest number, 4,945,261, valued at \$91,256,301. Iowa comes next, with 3,040,887 cattle, at \$85,302,255; Missouri, 2,009,647, at \$49,087,375; then Kansas and Nebraska.

.

THE entry of beef and cattle into the American foreign trade was a point dwelt upon by Mr. Commissioner Loring, who gave some comparative tables, showing the growth of this branch of commerce during the last four or five years. The exports of beef during the fiscal year ending June 30, 1884, were—

	lb.	\$.
Fresh beef	120,784,064	11,987,331
Beef, salted or cured	43,021,074	3,270,083
Beef, canned	...	3,173,767
Total value for 1883-84	...	18,431,181
Total value for 1882-83	...	16,663,345

The exports of fresh beef exceeded those of any previous year. The nearest approach in former years was 106,004,812 lb. in 1880-81. The export price in the year 1883-84 averaged 9.9 cents per lb. The number of cattle exported also largely increased, being 190,518 against 104,444 the previous year. There were about 360,000 slaughtered beeves exported, which, with 190,000 shipped alive, make a total of 550,000 beeves exported. Exports of cattle were formerly of the long-horn race from Texas and Florida to Cuba and neighbouring islands. They were valued at \$16 to \$17 per head at most, and those of Florida sometimes \$13 to \$14. This southern trade had little variation and little growth from 1850 to 1877, when the era of exports of fat beeves to Europe began. The northern exports from 1870 to 1876 inclusive did not much exceed 1,000 annually, but increased with wonderful rapidity after 1877. The exports from Boston and New York show this increase, and the miscellaneous exports have been mostly from northern ports. The largest proportion of these exports have gone to England, though they have found distribution in Scotland, Germany, Belgium, France, Cuba, and other countries. The trade to Mexico is mainly young or stock cattle. Cuba takes beeves of the Spanish type at a low value. Canada receives stockers and beeves of northern breeds at much lower prices than the fat and heavy beeves shipped from New York and Boston.

.

THE report for February on the prospects of the wheat crop in the Berars is as follows:—"Wheat crop in good condition and nearly reaped. Area under crop 2 per cent above average, being 819,033 acres average yield generally reported; it is anticipated that the total outturn of the Province will come to 122,000 tons. At beginning of year, 40,496 tons wheat was in store; of this 16,600 tons were exported to end of December by rail."

.

THE areas of unreserved forests under the control of the Forest Department have decreased by 245 square miles. During the last camping season it was discovered by the Divisional Officer in the Lahore Division that settlements were forming in our unreserved *rakhs*. This might have become a danger to complete control over these *rakhs*, and at some future time have affected the very area of Government property by the acquirement of rights. The history of these settlements is that in such *rakhs* where *zeinindars* and others had been allowed to graze their cattle, either under contract or on *tirni*, they had built themselves huts of grass and mud, and constructed cattle-sheds. These were at first of the most temporary character, but since then people always returning to the same *rakh* have made themselves more comfortable, and these huts are now never pulled down and are rarely unoccupied, and have been added to year by year. The majority of these settlements have been started within the last six or seven years by villagers whose cattle have increased to such an extent that they have been obliged to almost permanently remove from their original

villages. They bring their families out into the *rakh* during the winter, and only send them back to their parent villages during the hot season. These settlements have now in the Lahore Division all been carefully measured up, and a ground rent of one rupee per *ghumao* is levied from the occupiers, and an agreement is taken from them stating that they have no right or claim to the land, and that Government may turn them out at any time without compensation.

**

The management of the grazing areas in the Punjab is a question of great importance and great difficulty. The inhabitants of the great southern Bar districts are entirely dependent on it, as the annual rainfall is by no means in every instance sufficient to permit of agriculture being carried on as the main means of livelihood; moreover, the water is in very many places too far from the surface to allow of extensive well-irrigation. Altogether these people live under difficulties from which the inhabitants of the happier situated irrigated districts and the districts underlying the Himalayas are luckily exempted. If left to themselves, the dwellers in the Bar will permit their herds to increase in favourable years, and consequently suffer still greater hardship in years when rainfall is scarce. It will be therefore our duty to create much more extensive grass reserves for such eventualities than has been done as yet. The scarcity of grass occurs both annually and periodically, and two kinds of reserves should consequently be created; those to supply the annual want to be opened in those months when the scarcity in the outlying grazing-grounds is mostly felt, which may be earlier or later in the season according to the rainfall of the year, but falls as a rule between October and the summer rains. The latter reserves, those closed for periodical scarcity, should only be opened when such extreme scarcity really occurs, though in other years the cutting of grass might be allowed in them at the end of the season. In the plains districts, which are either irrigated or which underlie the Himalayas, and have consequently a sufficiency of moisture and rainfall, the grazing question, though it may become an annoying one, can never be one of the same vital importance. In the Lahore District the steadily increasing pressure of cattle-owners into Government *rakhs* indicates a large increase of cattle, but though they may have to be stall-fed at some future time, it will always be possible to produce sufficient food for them on irrigated land.

**

The grazing in the lower hill districts is partly local, partly pertains to the vast system of Himalayan grazing. Far away in Chamba, Bashahr, Kulu and Cashmere, and even in Spiti and Lahoul, every summer opens immense grazing-grounds of the richest pasture. The proprietary right of these is, as a rule, only claimed by the ruler of the country, and every comer may graze his cattle, sheep or goats for a small fee. The natural consequence of this is that people from all countries within reach of such pasture-grounds flock to them. Their herds increase rapidly under the most favourable conditions, and when winter begins to cover the rich pasture-land with snow, they have to retire from the Alpine regions to the winter grazing-grounds in the outlying hills, the areas in the interior valleys, which are not always even sufficient for the local herds being by far too cramped to receive them. The consequence is that large, and, it is feared, increasing, numbers of animals have to be wintered in the lower hills of the Punjab, which certainly bear the traces of a long period of this annual inroad. This evil can only be alleviated by the creation of forest reserves and their strict closure.

**

The higher hill forests suffer mostly from local herds which have been wintered in the upper valleys. These herds are not very extensive, and there is no fear but that the question with regard to them will gradually settle itself. By judicious management much has already been done in this respect in the Bashahr Division and the Bhandal valley in Chamba, and there is every reason to believe that in the rest of the country it will in time be settled as satisfactorily. In the most western and most eastern divisions of the Punjab, we are threatened by an inroad of Gujars. In Hazara this is due to our mismanagement immediately after completion of the Hazara Settlement.

We allowed the villagers to enter our forests and graze their cattle in our reserves, and the villagers not requiring their own land leased their guzaras to Gujars. These nomads once admitted are difficult to get rid of, but during the last two years they have either retired or settled. In the Bashahr Division the Gujars approach by the Pubbar. The maximum number to be allowed into the forests of that valley was two years ago fixed at 500 head of buffaloes, but at present some 4,000 are said to graze within that valley. They have tried to sweep down into the Nogli and Behra valley as a route to new pastures; but luckily a belt of reserves extending from Hatta to Moral Peak lies straight across their way of ingress. The reservation of these areas is most popular with the people of the Nogli Behra and Sutlej valleys.

**

The following information has been furnished regarding the area under wheat cultivation, and the probable outturn in the Native States under the Central India Agency, during the year 1881. The figures are founded on a rough estimate:—"In Gwalior, area 1,037,491 acres, outturn 4,407,894 maunds; in Bhopal, area 1,781,706 acres, outturn 6,585,160 maunds. For some of the States information is still wanting; in Baghelkhand, area 410,161 acres, outturn 1,321,432 maunds; in Bhopawar, area 167,589 acres, outturn 815,435 maunds; in Chaukhari, area 41,660 acres, outturn 256,573 maunds; in Goona, area 21,505 acres, outturn 155,832 maunds; and in Bundelkhand, area 184,220 acres, outturn 423,905 maunds. Information regarding the Western Malwa States is still wanting. From the statistics at present available, the total approximate area under wheat in the Central India States is therefore 3,670,394 acres, and the probable outturn, 13,966,131 maunds."

THE AGRICULTURAL COLLEGE AT CIRENCESTER.

WITH two or three young Bengalees amongst us, who have returned as successful graduates from the Agricultural College at Cirencester, the Lieutenant-Governor should not permit them to bury their talents in a napkin, as ordinary members of the Statutory Civil Service. Give them this status by all means, but devote them to the purpose for which they were educated. If we were Mr. FINUCANE, we could find we think, something better for these young gentlemen to do, than the outline grind of the Civil catcherry. Send them out as lecturers on 'how to improve agriculture,' into the Mofussil towns and villages. There are but two or three of them we believe at present, while our administration is so nerveless that having trained and educated them, we are now puzzled what to do with them. Give each of them at once, a proper laboratory for the pursuit of agricultural chemistry, in connection with one or other of the great centres of our educational efforts, and set them to work upon qualitative analysis of all the staple products of the province, and of its soils. Require them to publish their analyses, and an account of their work, not in the official *Gazette*, but in the newspapers, or better in the *Indian Agriculturist*, the *Tea Planters' Gazette*, and the *Indian Planters' Gazette*. Give them respectable salaries to start with, not extravagant, but such as well educated and able young native gentlemen and scholars might reasonably expect. But above all trust them, and instead of putting them strictly under the Educational department, point out to them that their mission is to awaken the bucolic mind of Bengal, and that what you ask is that they address themselves to the task as earnest workers, adopting their own methods, and reporting at intervals with honest candour, exactly what they have done and are doing. We have seen two or three of these young gentlemen ourselves, and think very highly of them, and we are most averse to their being absorbed in the ordinary hum-drum ranks of the Statutory Civil service. If there is anything in them—and we certainly think there is—set them at once to work, as lecturers upon scientific and practical agriculture, giving each of them a laboratory, as we have said, at some great educational centre, where they might perhaps deliver a course of lectures twice a year. But freedom to them to choose their own methods of approach to the mind of the peasantry, is the first condition of all in our own eyes. Government cannot lay down rules for the conduct of such

work, for it is of the pioneer order. We have spent a lot of money in the education of these young men, and they are back amongst us, with the 'hall mark' of academic success upon them. What we want them to do, is to administer a shock to the Indian peasant's mind, of the same order that our peripatetic lecturers gave to the minds of British farmers, forty years ago. The Lieutenant-Governor takes a wise interest in the new Agricultural Department, he is organizing. Well, send these young men out as light horsemen, to make known everywhere what the Government hopes to accomplish. By their mixing freely with the people, and lecturing, with 'chemical illustrations,' before every audience they can get, they may do real work we believe in the mofussil. What does it matter if their first efforts fail? It will be easy—if these young men are what we think they are—to create a good deal of excitement and interest in their work, all over the Province. It is better that their connection with the Government should be as slight as possible, for the sake of giving them perfect freedom of method, and securing the ear of the people. To permit them, now that we have technically trained them, to be absorbed in the ordinary Civil Service, will be another of those mistakes we are constantly committing, through want of considering what we wish to accomplish by the money we spend.

We started the *Indian Agriculturist* ten years ago, for the purpose of making it a sort of centre, or focus, in which the public and the Government itself, might find a contemporaneous record of all that was being attempted in the way of improved agriculture all over the country. We never had any hope of making it an 'authority' upon Indian agriculture, but a Gazette in which every fact of interest connected with the ordinary agriculture of the country, and every experiment made, in the hope its improvement might be recorded for reference in years to come. There is no journal in India devoted to the ordinary agriculture of the country except this one. The planters have their Gazettes, very efficiently conducted, but 'planting enterprise' lies outside the scope of general agricultural improvement altogether. We have tried to induce the various Governments of the country to co-operate with us, in getting up a really valuable paper devoted to the improvement of the ordinary agriculture of the people, but have not had very much success as yet. With the advent of these young men from the Agricultural Colleges at home, something ought to be at last done.

FORESTRY IN SOUTHERN INDIA.*

We have received a copy of this book of 140 pages octavo. The author, from his long experience of Indian Forests, has a right to speak with authority on a subject which can never fail to be of interest to the Indian Government. Forestry in India has always held a prominent place in the economy of the land. It is a subject of so much importance, that nothing that tends to increase our knowledge in this direction should be lost sight of. Nearly everyone is alive to the great influence exercised by forest trees on the health and well-being of man, and the part that vegetation plays in the regulation of the seasons is perhaps not the least of its functions. Apart, however, from these considerations, it is essentially necessary that our Forest Officers, who come out generally with a training in the Forests of Germany, should have a hand-book to guide them in the satisfactory performance of their duties in India. A book in short that will furnish them with every information as far as possible. General Morgan rightly says that the duties required of a forest officer are multifarious. "To be really useful," he says, "he should know the language of the people, without which he is useless. . . . In addition to the language, he must know the habits and customs of the people; then arboriculture in all its branches; next engineering and surveying, how to build houses and bridges, survey roads and blocks of forests, &c., run boundaries by a pick-axe trench. . . . Physic his people when ill, treat them with tact, attend to the health of his bullocks and elephants, . . . and keep his own health;

answer endless letters, and understand accounts." General Morgan has produced an admirable little treatise on Indian Forestry, which will not only apply to Southern India, but we think to all parts of India. His remarks on the management of Teak Forests are fraught with singular practical knowledge come of long experience. At page 8 he refers to the unwise policy of constant change of appointments in these works: "A Forest Officer had no sooner established an understanding with the Collector and got things to work amicably, then there came another Collector, who had quite different views and ideas, and every thing went to ruin. One member of Council was in favour of shutting up the Auamallies, another was not, and so the matter went on until what ought to have been an admirable department storing up the sources of a large revenue for future years, became like a certain other department, not a saving department, but a spending one." These remarks apply with equal force to many other departments of Government, where a constant change of staff subverts the labours of the one immediately preceding. General Morgan's remarks (page 29) on the decline in the quality of Teak timber obtained from Pegu are worth noting. He ascribes the cause to "girdling."

The Sandal wood tree (*Santalum Album*) is treated of in a way that admits of no doubt. This tree is one of the most valuable we possess from a pecuniary point of view. It is much in demand in the China markets, and the price varies from three to six annas a pound.

The remarks on dry forests are full of instruction. Fires are looked upon as being both beneficial and injurious. "They render the jungle less pestiferous, and the grass comes up earlier, but fires ruin saplings, and should never be allowed in reserved forests." In his general remarks (page 40), the author makes the following trenchant observation: "What has already happened in Algeria threatens to occur here, unless speedy measures are taken to secure reserves, and save what yet remains of existing forests. Fire and cattle are worse even than ryots, and should be excluded. Perhaps when Collectors are Conservators, they will be able to use their authority to more effect than the Forest Department has been able to do. I quite agree . . . that there is enough for all, if it is properly conserved, but that is the difficulty. In vain does the Forest Department try to save the ryots from themselves, their improvident habits too surely destroy the jungles which ought to last them for centuries."

The book contains a list of useful Forest trees, with remarks for their proper cultivation and treatment, and concludes with the author's two prize essays on fuel plantations; humus and the defertilization of forest soils, etc., in India, and forest products.

The work is a practical guide for Forest Officers, and Government cannot do better than place a copy in the hands of every forest officer in the service.

TEA CULTIVATION IN CHINA.

It appears that the decrease in tea exports from China has awakened the tea merchants of Foochoo to a sense of their situation, and to the danger which threatens their tea trade at the present time. In view to improving the present unsatisfactory condition of things, the tea merchants of Foochoo—a place well-known as one of the principal ports in China for black teas—have addressed a circular letter to the various Chinese hongas and dealers, drawing their attention to the unsatisfactory condition of the foreign tea trade, which, it is pointed out, is due to the deterioration in quality that has of late years marked the teas exported from China. It reminds them of the serious decline in value in the London market of nearly every description of Foochoo tea, which in many cases amounts to fifty per cent. It goes on to say that during the last ten years India has gone on increasing her exports of tea, and improving its quality by greater care in cultivation and manufacture; and the tea growers of Foochoo are requested to evince more care and management with their trees. The authors of the circular seem keenly alive to the causes that have brought about the present low quality of much of the China teas recently exported. As a means of counteracting the evils complained of, they call upon all tea growers to follow the

* "Forestry in Southern India," by Major-Genl. H. R. Morgan, late Deputy Conservator of Forests Madras. Edited by John Short, M.D. M.R.C.P. and S. F. L. S. etc., Retired Deputy Surgeon-General Madras Army. Higginbotham & Co., Madras.

methods that should be adopted to secure a crop which will be good in quality, and fetch a good return in the London market. The method recommended is that tall trees should be pruned annually and reduced to low stature, and that 5 to 10 per cent of the old trees should be cut away annually, and these replaced by new ones. They should be well manured; and, in picking the leaves, a distinction should be made between the old and the young. "Beau cake" is recommended as a good manure; but before manuring, the old earth should be removed and replaced by new earth. By this means, the growers are told the color and taste of the leaves will be perfect.

With regard to plucking, to which much importance is attached, the following instructions (which are remarkable for force and clearness) are given:—

"The picking of the leaves should be promptly made according to the time, and the growers should by no means allow the time to pass without picking them. At the present moment, tea leaves in the Fuhkura province are usually picked after a lapse of three or four days beyond the proper time. This practice has an injurious effect, as the leaves cannot stand the temperature, hence the finest leaves become coarse. Those who wish their trees to produce the finest leaves, will do well to pick them according to proper time. This is a matter of vital importance. At the time of picking, the leaves should be divided into first, second, and middling qualities; when this is done, they should be placed in separate baskets to prevent their mixing up. This practice was in vogue in former times. The leaves should be sieved several times, after which they should be divided into first, second, and middling qualities."

That the Chinese are becoming thoroughly alarmed at the threatened danger to their old industry, there cannot be the smallest doubt, and the issue of such a circular by the Chinese is a proof that the danger is real, and further that they seem determined to improve matters. Our Indian tea planters will do well to look to their laurels. India is marked out by the Chinese as their natural rival in tea, and we would invite the serious attention of tea planters to this matter. The methods adopted by the Chinese to secure a good crop may perhaps prove useful, and keep before their minds some very useful hints which, perhaps, do not always occur to them at the proper time.

THE JUTE INDUSTRY IN GERMANY.

CONSUL GENERAL VOGELER has just issued a most interesting and comprehensive report on the jute industry in Germany. Much attention is being devoted in that country to extending a business which, during the last few years, has developed to large proportions. Referring to the plant, he says, "the principal requisite for its cultivation is a moist, warm climate; given such a climate, it will thrive almost equally well in the low lands and on the plateau." Of course, there being no plateau land in Bengal, which has been successfully cultivated with jute, we have no means of ascertaining the correctness of the opinion, but there are certain other conditions necessary for the growth of the plant. Although it luxuriates in a hot damp climate, there should not be too much rain, especially in the early part of the season; in exceptionally dry seasons we frequently find crops standing through the cold season which the cultivator did not regard as worth cutting. It is almost unprofitable to cultivate jute upon laterite and open gravelly soil, but it will thrive upon a loamy soil or rich clay and sand. The finer qualities are produced upon the higher lands, known to the ryot as *sunn*, adjoining their homesteads upon which the *aus* paddy, pulses and tobacco are planted in rotation. The coarser qualities are grown principally upon *chirs* or mud banks and small islands on rivers. The soil is prepared at different times according to the position of the land; if it is low-lying and there is apprehension of early flooding, it must be ploughed earlier than higher lands. The more clay in the land, the oftener it is ploughed before sowing. In the former case the land is prepared in November and December, and in the latter in February and March. The soil is ploughed from four to six times, the clods are reduced to powder, and at the final ploughing, the weeds are collected, dried, and burned. The sowings commence according to the position of the soil about the middle of March and extend to the end of

June. General Vogeler says:—"The amount of seed required is from 20 to 30 lbs. to the acre. Cutting commences from 12 to 15 weeks after sowing. The plant reaches a height of 10 or 12 feet. The average yield of fibre is 2,000 lbs. per acre." The seed is seldom purchased. The cultivators allow a number of plants in a corner of the field to ripen into seed, and these are used the following year. In the matter of outturn, however, it is difficult to make an assertion authoritatively, or with any degree of accuracy. As the crop is entirely dependent upon the season, it varies considerably; sometimes the yield of fibre per bigah is 5 maunds, at others it rises to 10 or 12 maunds, while in some parts of the country the average crop is 1 to 2 or 3 maunds. The plant is cut when blossoms appear on it, and past season when the fruits appear. In the former stage the fibre is a little weaker than the other, but it is finer and has a gloss which recommends it to the purchaser. The fibre is separated from the stalk by a process which is known as retting. In this connexion M. Vogeler says:—"Flowing water is preferable because it bleaches the fibre, making it almost perfectly white, but the process of separation is quicker in standing water." Here his information is at fault. It is true in some districts bundles of jute stems are submerged in rivers close to the bank, but there is some danger attending this process. The river is at this season of the year very high, and the current strong; if the palings with which the bundles are secured to the earth are removed, the entire quantity will be washed away. It is therefore a common practice to steep them in tanks and stagnant pools, and place weights on them to make them sink below the surface of the water. "The period of retting," says an Indian writer, "depends upon the nature of the water, the kind of fibre, and condition of the atmosphere. It varies from two to twenty-five days. The operator has therefore to visit the tank daily, and ascertain, by means of his nail, if the fibre has begun to separate from the stem. This period must not be exceeded, otherwise the fibre becomes rotten and almost useless for commercial purposes." The following interesting account of the way in which the fibre is separated from the stalk is taken from Royle's *Fibrous Plants*. The operator having taken his stand in the water up to the waist begins "to remove small portions of the bark from the ends next the roots, and grasping them together, he strips off the whole with a little management from end to end without breaking either stem or fibre. Having brought a certain quantity into this half-prepared state, he next proceeds to wash off; this is done by taking a large handful, swinging it round his head, he dashes it rapidly against the surface of the water and draws it towards him, so as to wash off the impurities; then, with a dexterous throw, he spreads it out on the surface of the water and carefully picks off all remaining black spots. It is now wrung out so as to remove as much water as is possible, and then hung up on lines prepared on the spot, to dry in the sun." It must not, however, be supposed that as a rule the bundles are stacked in water immediately after being cut. In some parts of the country they are allowed to remain where they are cut for the leaves to decay, as the latter are supposed to discolour the fibre in the retting process. However this may be, it is supposed that the fibre is benefitted in this process, since it is found to separate more easily from the stems and runs no risk of rotting by over-maceration. The Consul-General is a little unfortunate in the figures he quotes. He says—"The export from Calcutta . . . now amounts to 8,000,000 cwts. per year. About one-tenth of this amount is imported into Germany." Now referring to the annual statement of trade and navigation for 1881-82, we find that the total amount exported amounted to 7,510,314 cwts., of which Germany absorbed 33,804 cwts. only. This is the smallest quantity taken by any country in the world with a rising industry. Even Egypt consumes almost a thousand cwts. more than Germany. As a matter of course, the United Kingdom take the lead with 5,637,534 cwts., then comes the United States with 1,431,014 cwts., next France, 141,181 cwts., Austria 105,540 cwts., Italy 82,308 cwts. The process employed to manufacture jute products is similar to that employed in the manufacture of linen and cotton goods, but productive of less dust, and hence is less detrimental to the health of the workmen. The process of bleaching jute has not yet reached that

point of perfection at which it may be performed without lessening the strength of the fabric. A great many fabrics are already being made out of jute. In addition to carpets and table covers, a new material called "jute velvet," adapted for furniture coverings, curtains, and wall hangings, is rapidly coming into popular favour. The body of the velvet consists of cotton, and the pile is made of jute. This pile is produced like other velvet piles, and by a simple process designs can be pressed into it according to the nature of the use for which it is intended. This jute velvet is very durable, and not liable to be injured by moths.

In Germany the jute industry is about sixteen years old. The first factory was established at Vechelde, near Brunswick, in the year 1868; since then others have sprung up in Hanover, Oldenburg, Bremen, Gera, Meissen, Potsdam, and lately in Berlin. It is estimated that at present this industry is represented in Germany by about 50,000 spindles and 4,000 looms.

It is claimed that the products of these German jute factories are in no way inferior to those of Scotland. The production of German jute mills last year amounted to about 70,000,000 lbs., which is estimated to have supplied about three-fifths of the home demand.

Miscellaneous Items.

THE Metropolitan Horse Fair will take place at Rawul Pindie this year as usual.

ON account of the Rawul Pindie Assemblage, the Lahore Horse Fair, which was to have been held on the 27th instant, has been put off to the 8th proximo.

DURING the month of January, 240,515 cwts. of wheat, valued at Rs. 9,13,605, were shipped from ports in Sind.

ACCORDING to the latest report, the season has been a favourable one for the opium crop in the N. W. and Oudh Provinces, and the collection of opium has begun in several districts.

ON the representation of Messrs. Wilson and Darrah, the Government of the North-West Provinces and Oudh have placed at the disposal of the Agricultural Department a sum of Rs. 10,000 for the formation of fuel and food reserves.

A CORRESPONDENT says:—"Mikani's guaro, a composite plant of South America, is an antidote to snake-bites. A tincture is made by infusing the leaves. The infusion is drunk, and the hot leaves are applied in the form of a poultice to the bite."

THE crop and weather report, as regards the Oudh districts, shows that the increasing heat is being generally felt. The wind is strong from the west, peas are being cut in places, opium extracting is in progress, prices are steady, supplies abundant, and the general health good.

A MEERUT correspondent telegraphs that the Nauchande Fair was opened by the Duke of Connaught, and promises to be a great success. An immense concourse of people have assembled. Cattle and horses and various wares have been brought to the fair in great numbers.

It having been fully demonstrated that it is hopeless for a native plough to compete with any chance of success against a mould-board plough, working for the same time on an equal area of the same kind of land, the Madras authorities have decided to open separate competitions for native ploughs only. A stronger proof of the inefficiency of the native implement could hardly be afforded.

THE late Earl of Lauderdale's wine was sold at Edinburgh a few days ago. The great specialty was some sixty dozen of 1820 Madeira, bottled 1844, with the following label in the cellar book: "This wine went out to India and China with Captain Sir Thomas Maitland." There were also six dozens Madeira of fabulous age, labelled "Brought home by Sir A. Maitland, from West India, in the *Pyre* frigate."

THE cry now all over Bangalore is—"Where are we to get our water if the rains hold off? Sampang tank, dry; Miller's basin, with only a month's supply; Ulwar subsidiary reservoir, dry; Ulwar tank, barely two months' supply; Shoolay tank, dry; and all smaller govt. completely parched. Where are we to look for the precious element? If some of our energetic members of the Municipal Board, instead of wasting public money on dispensaries and police wards, which are certainly useful works in their way, would give way to the more urgent need of providing water to meet the impending scarcity, by sinking ordinary pot wells in likely localities, we believe that much good could be done. A well of this kind, 50 feet deep, costs 25 rupees, so that several hundred of these might be sunk all over Bangalore, for the sum proposed to be spent on either the new Ward, Bowring Hospital, or the Ulwar Dispensary."

THIS season's kheddah operations in the Garo Hills have so far been most successful. Between the 7th January and the end of last month, Mr. Sanderson and his party had succeeded in netting 161 wild elephants. Operations were still proceeding when the last report was received. The relative importance of the enterprise in the Garo Hills is shown by the fact that the recent extensive operations in Dehra Doon only resulted in the capture of 36 live animals.

AN official return of the sales of sandal-wood in Coorg for the past five years shows that 100½ tons of the wood were sold on an average each year at the rate of Rs. 343 per ton. The largest quantity was sold in 1882-83, when 192½ tons were disposed of, and the smallest quantity was sold in 1883-84, when only 36½ tons were sold. The highest price was also realised in 1882-83, when the wood brought Rs. 402 per ton; the lowest price realised Rs. 231 per ton in the year 1881-82.

THE latest reports from the indigo districts in Behar are generally favourable. Sowings are now nearly completed, and the plant is reported to be looking very healthy, whilst the late re-sowings are also coming on well. In one or two factories in Monghyr and Chupra the young plant is said to have suffered from the west winds and irrigation has become necessary. Throughout Lower Bengal the plant is much in want of rain, but, considering the weather, it is doing well.

EXPERIMENTS are being made, according to the *Polytechnische Notizblatt*, in Paris with a new alloy having a white color, yet containing no nickel. It is said to be very strong and malleable. It is made of copper and ferro-manganese, the proportions being varied according to the purpose for which the alloy is to be employed. An alloy of forty parts of copper and sixty parts of ferro-manganese with a suitable quantity of some appropriate flux produces a metal of such tenacity that it surpasses the best steel armour plates.

THE Surat Akhbar says that the Bombay Government has at last done justice to fishermen, who were hitherto unable to obtain and use one-fourth of the quantity of salt necessary for salting fish. The result was that a fisherman sold unsalted, and often putrid fish to the people. In consequence of this, Government have directed that salt depôts should be opened on the shores of Balsar and other places inhabited by fishermen, whence salt will be supplied them for fish-salting purposes without any, or at comparatively low duty.

THE Blue Mountain Range in New South Wales is much frequented by fern-hunters, especially in the vicinity of Mount Wilson where the summit of the ridge is largely covered with a dense growth of eucalypti, the mere trunks of which almost obscure the horizon, and in the undergrowth it is no exaggeration to say that thousands of tree-ferns, ranging up to 30 feet in height, are visible in every direction. It is on the southern slopes that the *sassafras* is found, in which mosses and orchids luxuriate, and festus or lanas hang from the topmost branches.

THE serious losses that Queensland pastoralists have experienced from the severe drought of the last 18 months were illustrated in the half-yearly report of the Squatting Investment Company, submitted to the shareholders last month. Although the Company went extensively into tank sinking immediately after purchasing their property, it was too late, and for 18 months there has not been sufficient rain to put any water in the tanks. The Company has lost over 100,000 sheep in 18 months, although its property is said to be one of the finest stations in Australia.

BESIDES the unusual pressure caused by the camp at Rawul Pindie, the Sind, Punjab, and Delhi line will have an extra strain on its traffic owing to the Hurdwar Fair, which is expected to be on a very large scale, owing to the Koomh which recurs every six years. The fair does not commence till the 13th April, but the pilgrims from the Punjab are already pouring into Hurdwar. The East Indian and Rijnpooteans lines will also have to run specials to meet the extra traffic for Saharunpore. It is hoped that the branch line from the latter station to Hurdwar will be ready for traffic by the end of the month.

LANTANA, called the planters' curse in Coorg, does not appear to be so black as it is painted. It is remarked of this plant that its growth in Coorg is very vigorous, and the spread of lantana in the Attur Forest close to Fraserpet is said to be truly wonderful, and may be expected in time to improve the character of this forest; while in and about Merora the growth of young forest trees under the shelter of the lantana is most marked. At present, therefore, the spread of the lantana has its value by making the forest impenetrable, and leads to the hope that it may enrich the soil of abandoned estates which may be overgrown with it.

THE enquiry instituted by the Department of Revenue, Settlement, and Agriculture, last month, regarding the alleged ill-effects of the *Erythrina indica* (Dahlia or Indian coral tree), in producing leaf disease when planted for shade among coffee trees has, according to Mr. W. Wilson, the Director of the Department, elicited replies from several gentlemen well qualified by their practical knowledge to speak with authority on the subject, to the effect that there has not been observed in southern India any connection between the presence of *Erythrina* trees and the production of leaf disease, but that on the contrary the effect of planting *Erythrina* has been distinctly beneficial, not harmful, to the coffee trees which it is planted to shade. The replies given are in complete accord on the point.

An attempt is about to be made in the N.-W. Provinces to secure protection for the cattle in time of scarcity, and to benefit agriculture generally by organising, through Government agency, fuel and fodder reserves. A scheme has been prepared and submitted to Government by Mr. Wilson and Mr. Darrab, on the receipt of which the Local Government placed a grant of Rs. 10,000 at the disposal of the Agricultural Department for the formation of fuel reserves in the Alighur district. Suitable plots in the district have already been selected, marked out and surveyed, and an application will soon be made to Government for their utilisation.

NORTH BORNEO bids fair in the future to rival Singapore in the timber trade. At present the barque *Ellen* is loading a cargo there for one of the Australian ports, and this is the second large shipment to the Colonies, a former one having been made by steamer. The wood shipped is something similar to our sarayah, and it is expected that a large trade with Australia will in time spring up. It appears that in all countries a soft easily worked wood is the most useful, but there are, besides, many fine kinds of hard timber in the North Borneo forests, some of which cannot be excellent in any part of the world.

The following extraordinary statement is from the *Electrician* of the 7th February:—"A new process was recently tried in America for sugar refining, in which the principal agent employed is electricity. The cost is said to be not more than 3s. 4d. per ton, and the result a hard sugar of almost absolute purity without any syrup whatever." As the cost of refining under the present remelting processes varies from £3 to £5 per ton, the above alleged discovery would be a startling one if it were true; possibly the cost of electrical refining should be given as 3s. 4d. per cwt., and not per ton. Sugar refining at a cost of 2d. per cwt. appears far too good to be true.

SIR SAMUEL BAKER recommended a new product when he called at Colombo. He said to the representative of the *Oryton Observer*: "When I was in Japan about two years ago, I sent to my relatives at Nuwara Eliya (Ceylon) a large quantity of the seed of the lacquer plant, and Mrs. Baker told me she has got a lot of young plants from the seeds. It struck me that this might be a new product worth growing. I am sure Mrs. Baker would be very happy to give any information on the subject. I was the first to introduce it into England. I have got large quantities in my garden. It should grow beautifully on the hills here, much better than it grows in England. It is a very valuable plant: in Japan it is considered of great value."

THE Dhurumsey Mill, Bombay, has at last been closed for want of funds. This mill stands third in the world, and is the largest in the whole of India. The cloth it manufactures is considered good; but it seems to have seen the light under an evil star, for all who have ever been connected with it have been ruined. Since the time of Dhurumsey Poonjabhoy it was a white elephant in the hands of the Pandays. The shares, originally worth Rs. 2,000, are now unsaleable at Rs. 150. By the closing of the mills about twelve thousand workmen have been thrown out of employment. We understand that the two chief creditors of the mill, Messrs. Ooculdas Madhoojee and Kesoojee Jadoojee, have some dispute with the agents, who have no funds in hand for the working of the mills.

We hear that the Kumaon Iron Works Company is extinct. Some of our readers will remember that this Company was first established in 1860, with capital largely supplied by persons connected with Kumaon and the vicinity, and that at the time great expectations were entertained of large profits from iron-working. The capital was much too small, and was soon spent, and the works were suspended for many years. The shareholders, after many ineffectual attempts to raise fresh capital and to establish claims upon the Government for reimbursement of money invested, have at last agreed to accept an offer by the Secretary of State to take over all the works, upon payment to the Company of about Rs. 37,000, in full satisfaction of all claims. This sum will be distributed *pro rata* among the shareholders.

Messrs. GILL, DEANE & Co., of Guntur, write:—"We had a good crop both as to quantity and quality and good prices, but the encouragement given by some buyers to adulteration, and upon which subject we have continually reported, since our circular of 14th November 1884, has culminated in such a state of affairs that should give those who are responsible for it, very good reason to remember this season as a warning in future. What little publicity we have afforded to those malpractices appears to have been unneeded, but we can add now that if the same buyers receive any real help from Madras, Guntur business had better be abandoned. We have done what we can to remedy the evil by attempts at joint action locally, but when the time came, those who joined us had not the courage to maintain their promises."

A curious cattle-disease has made its appearance in the You Yangs district in the colony of Victoria. An Australian paper says:—"Mr. Kendall, veterinary surgeon, has furnished a report to the Government on the cattle-disease in the You Yangs district. The report states that during the past four years, since the disease broke out, 700 or 800 cattle altogether have died of it. In the digestive organs of the dead animals considerable quantities of rabbit-bones were found, which Mr. Kendall has no hesitation in pronouncing form anthrax or blood-poisoning. The predisposing cause of this is the bad quality of the water, and the fact that the alkalis which the water contains give animals a depraved taste for chewing animals' bones. The blood of the animals was observed to contain bacilli, not in large numbers, and bacteria were discovered in the water that the animals drank."

A MEETING of the members of the Bombay Millowners' Association and others interested in the mill industry was held last week, to consider the advisability of closing the mills two days in the week, in view of the present depressed state of the market. Mr. Jehangeer Hormusjee moved a formal proposition to this effect, and it was seconded by the chairman, Mr. Dinshaw M. Petit, who observed that a reduction in the production of yarn and piece-goods would tend to an increase in the price. Mr. George Cotton said that he, having carefully considered the question in conjunction with his co-directors, had arrived at the conclusion that the proposal before them, if carried out, would effect an increase in the cost of production, and would make the small margin of profit which they now obtained, smaller still. After a good deal of desultory conversation, the original proposition was withdrawn in favour of one moved by Mr. Cotton, to the effect that it would be to the advantage of the industry if the mills were closed one day in seven, exclusive of holidays, from the 1st of April to the end of the year. The proposition, having been seconded by Mr. Pearson, was carried unanimously.

Selections.

ENSILAGE.

MR. DAVID M'QUEEN, Wishaw Estate Office, favours us with the following:—

At first, like many others, and many still, I was somewhat sceptical about the fact of being able to preserve grass in a sufficiently wholesome state for cattle to eat without producing results detrimental to their health. But now that I have been thoroughly convinced from practical experience of the utility of silage, I am anxious to impress upon those engaged in the rearing and feeding of cattle the propriety of its adoption, as there cannot be the slightest doubt about its usefulness as an article of food for cattle, being both wholesome and nutritious. There is this, furthermore, in its favour, and which is a most important point, its adaptability to the climate of this country. The grass can be cut and ensiled in any kind of weather, no matter whether it be wet or dry. And there is still another very important recommendation—you can produce about four times the weight of ensilage that you can do of the same quality of grass made into hay.

The silo from which I obtained my experience was at one time an ice-house, but it has not been used as such for many years. It is built of solid masonry, on the upper edge of a sloping bank, and there is an opening in the upper surface of the ground, which was used for passing the blocks of ice through, and suited admirably for depositing the grass in the same manner. The lower opening, or passage, has two doors, an outer and inner, and is intended to prevent the ingress of air. The silo was filled at five different times. The first, on the 25th of June, was composed of short grass cut from the bowling green; the second, on the 26th of June, of plantation grass; the third, on the 3rd of July, of plantation grass also; the fourth, on the 8th of July, of meadow grass; and the fifth, on the 17th of July, of half-made hay cut from the policy grounds. The grass put in on each occasion was covered over with planking, and weighted immediately afterwards with about 26 lbs. to the square foot, and on the 5th of August the weight was increased to 80 lbs. per square foot, and the inner door of the passage on the side of the house hermetically sealed. These grasses, I may state, with the exception of the meadow grass, were formerly used almost entirely as bedding.

No salt was used with the grass when put into the silo. The silo remained in that condition until it was opened on the 16th of last month. When the weights and planking were removed it was found that the ensilage, to the depth of 6 inches on the top, was moulded, but even that the Galloway cattle readily partook of, although only put into their shed as bedding. The quality of the ensilage underlying the 6 inches or so of moulded stuff on the top is in splendid condition, and over forty cattle are being fed with a quantity of it twice daily, and one and all of them take it with great relish. I may likewise state that park deer have also had a trial of it, and although, when they felt the smell of it, they retreated rapidly, still a short time after there was not a vestige of it to be seen.

I have not been able to make any comparative test of the feeding qualities of ensilage as against any other kind of feeding for cattle, but of this I am convinced, it must be greatly superior to having the grass in the form of hay, as it must retain the most of the nutritive juices in the grass that in the process of hay-making evaporates.

I hope to hear of some inexpensive plan of silo being adopted, and so enable farmers to take the full advantage of the grass grown upon many farms, the making of which into hay our climatic changes frequently render an impossibility.—*North British Agriculturist*.

FISH AND FISHERIES IN THE UNITED STATES.

We have so recently referred at length to the activity and usefulness of the United States Commission of Fish and Fisheries, that we must be content on this occasion to direct attention to the appearance of another of the valuable and interesting reports issued by Prof. Baird. The volume before us extends over 1,200 pages, and is, where necessary, illustrated by lithographic plates or maps. An account is given of the new schooner-rigged vessel, appropriately called the *Fish Hawk*, which has been built for the special work of the Commission. Its three trips to the inner edge of the Gulf Stream slope resulted, we are told, in the discovery of a new and exceedingly rich marine fauna, "quite excelling anything hitherto encountered by the Fish Commission off the New England coast.... The bottom appeared to be nearly continuously covered with life, as the dredge and trawl seldom came to the surface without a load of interesting forms, demonstrating that the region was eminently well fitted as a feeding ground for fish, of which several edible species were taken by the *Fish Hawk*." During the year 1881 the "unprecedentedly large yield" of seventy millions of young shad was obtained, which was distributed by the officers of the Commission among the various hatcheries and eighteen States of the Union; this increase by more than 100 per cent is regarded as being due not only to the favourable fishing season, but also to the increased efficiency of the methods and apparatus of the Commission. As we turn over the pages of this volume, we observe much that we should like to quote or upon which we might expatiate, and we know that we should interest the naturalist as well as the fishery economist; but considerations of space forbid, and we must content ourselves with saying that we have here yet another monument to the energy of Prof. Baird, and to the wise action of a legislature which is now devoting a sum of no less than 70,000*l.* a year to the work of the Fish Commission. If the things in the sea that interest the British naturalist are things with which a British Government feels it can have no concern, is the same true of those things that might need a nation such as ours? When some are calling out that the state of our navy threatens us with a loss of external supplies of food in case of war, others among us are, it is to be remembered, feeling at this moment the want of a more plentiful supply of more nourishing food. It is for statesmen to decide on the value of considerations which it is the duty of the naturalist to submit, but the naturalist, entitled to have an opinion, watches with admiration the beneficent activity of the officers of the United States.—*Athenæum*.

ENAMEL FOR METALS.

The following is said to form a good enamel for cast iron, wrought iron, or steel, and we are informed that it will not crack on being subjected to moderate changes of temperature. When an opaque enamel is required, let us suppose, as a basis for vitrified photographs, about 3 parts of oxide of tin should be added. Take about 125 parts (by weight) of ordinary flint glass fragments, 20 parts of carbonate of soda, and 12 parts of boracic acid, and melt. Pour the fused mass out on some cold surface of stone or metal, and pulverize when cooled off. Make a mixture of this powder with silicate of soda of 60 B. With this coat the metal to be glazed, and heat in a muffle or other furnace until it is fused.

MAKING IT PLEASANT FOR THE HORSE.

MR. TORREYSON, the blacksmith of this city, is noted for his kindness toward animals. He has just built a road-cart, now on exhibition at his blacksmith shop, which is destined to revolutionize travelling by road, and to materially lighten the labor of that noble animal, the horse. The idea is to occasionally give the horse a chance to ride in the cart as the driver. The idea was first suggested to Mr. Torreyson by seeing a turtle move along the road carrying his shell with him. The vehicle made by Mr. Torreyson has four high wheels and the place between them is arched, so that the horse is hitched under the waggon between the wheels, his head projecting a little beyond the front wheels and his tail justly barely clearing the hind wheels. The driver sits just over the horse's neck and the others in the waggon face outward on each side. The horse is so fastened that the pulling is distributed over his body, and does not all come on his neck and shoulders. In this position he is greatly protected from the sun and storm, and thereby enabled to make long journeys with less fatigue.

But the principal part of the invention lies in a belly band about four feet wide passing under the horse. When you reach the top of a long hill, down which the horse would have to go slowly as he held back the load, you simply turn a crank, and it lifts the horse off his foot several inches from the ground, and the vehicle then runs down the hill of its own momentum. It is provided with a steering apparatus and a brake, that the vehicle may be steered and its velocity regulated.

Several times during the day the tired horse has a chance to ride, and is very much rested. Also when the horse attempts to run away, you wind up the crank, and he is lifted off the ground perfectly helpless.—*News Times*.

GERMAN SUGAR BOUNTIES.

THE following official returns of the Sugar trade of the German Empire are summarized from the *Journal des Fabricants de Sucre*. They put, in a striking tabular form, the rapid and vast increase in the production, the miserably small character of the home consumption, and the progressive decrease in the Sugar revenue, at a time when it ought to have been increasing by leaps and bounds, if the Germans were not debarred by mistaken laws from using their own Sugar. Instead of that, they are actually paying foreigners to use it. The net Sugar revenue in 1871-2 was £ 306,719 on a consumption of 221,793 tons. In 1883-4 the consumption was 349,671 tons, which, at £9 per ton, the German rate of duty, ought to have yielded a revenue of £3,147,039, instead of which the yield was only £1,755,863. The difference of £1,391,176 represents the increased export bounty, or, in other words, the sum paid by the German taxpayers to foreigners to induce them to use Sugar which in a natural state of things would have been used at home. This represents an average export bounty of 2*s.* 4*d.* per cwt. on the extra quantity exported in the time, a rate which in the current season of 1884-5 is expected to reach 2*s.* 6*d.* per cwt. Beyond this loss to the German taxpayer, the German producers of Sugar are understood to have lost £1,000,000 or £2,000,000 in the present season, in consequence of the production, artificially stimulated by Government, of a commodity which the tax will not allow to be used at home. Further, the German consumption, if Sugar were duty-free, ought far to exceed ours, so that there is a remunerative opening at home for 1,500,000 tons of Sugar a year, when the ordinary laws of supply and demand are allowed fair play. Instead of this, the German consumers have to pay quite 50 per cent more for bad Sugar than we pay for their own good Sugar. A more melancholy example of blindness to the truths of political economy it would be hard to find.—*Produce Markets' Review*.

HOW TO USE WHEATMEAL

By A. L. F.

FOR many years back doctors and sanitary reformers have been urging the public to use meal made from the whole wheat instead of so much fine white flour. Their arguments are convincing, their reasoning sound, so masculine wisdom whispers to the house-mother to try wheatmeal porridge. The good woman accedes, buys some wheatmeal and proceeds in the approved fashion just as she would for oatmeal porridge, and produces—like Tom Hood's schoolmistress—paste. At least, such is the juvenile comment at the breakfast-table—"Oh, ma, I don't like this." Papa says, "Nonsense, children; it's good for you." He does not relish it much himself, but it was his recommendation, and so he must stand by it. However, after a few mornings, the novel dish disappears from the scene, and wheatmeal porridge is silently, but none the less certainly, pronounced a failure. I speak feelingly, for this has been my own experience, and I feel sure that it has been that of many others. But those days are past. It is now possible to obtain wheatmeal specially prepared for making porridge and gruel. It is nicer than oatmeal, sweeter and more delicate, and is in summer a less heating article of diet.

To keep us strong and well we need three kinds of food; food to keep us warm, food to build up our bodies and sturdy mineral matters, such as phosphates, to make our bones firm and hard and nourish our brains, iron to make good blood, and so on. Now, all these are found in wheat. A grain of wheat under the microscope is seen to consist of a central white mass which is nearly all starch or heat-giving food. This is surrounded by darker layers which contain the gluten or flesh-forming substance, also the phosphorus and iron. And Nature, that wonderful chemist, has even enclosed in these little cells a substance called crealin, which has the power of partially digesting the starch. To make a fine white flower a large portion of these valuable constituents are left out and carried off in the pollard and bran, with the result that we have to make up for the lost nutriment by eating more meat, while the fine, starchy flour produces constipation, and even, according to some medical men, acts as a fruitful source of the dreaded disease, diabetes.

Practically, housewives will find there are two kinds of wheatmeal—one produced either by the old process of grinding between two circular stones, of which the under one is fixed, while the upper one moves; or very finely-ground by steel rollers. This is known in the trade as wheatmeal flour, and is in appearance like rather a dark flour with flakes of bran scattered through it. It is suitable for baking, and is manufactured by, I think, all the Melbourne mills. I may mention Messrs. Swallow and Arrell and Messrs. Gillespie and Co., as to makers whose meal I have often used and always found satisfactory. For bread and cakes nothing can be nicer, and a handful added to the flour when you are making a meat-pie or any kind of suet-crust, even for roly-poly or apple pudding, is generally thought an improvement by those who have tried it.

As porridge, however, it is an utter failure, most difficult to prepare without burning, and, at best, very unpalatable. I do not think any one could ever learn to like it. Yet wheatmeal porridge may be a delicious dish, fit for a prince; but before you try to make it, ask your grocer for "granulated wheatmeal." It is very like fine oatmeal, having, indeed, been treated in a very similar manner. Like oatmeal, it is kiln-dried previous to grinding. This process reduces the amount of moisture, and so far renders the meal more economical to the consumer, and, besides, makes the wheat crisp, so that the scarf-skin, or outer woody layer of coarse bran, is

INDIAN. AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA:—SATURDAY, APRIL 11, 1885.

[No. 15.]

Weather Report.

[BY TELEGRAPH.]

SIMLA, APRIL 9.

DEFICIENT reports have been received from Madras, and none from west Punjab. The barometer has risen, with a few local exceptions, chiefly in Hazarihgh and Goa. The two low-pressure areas still exist, but that over the Gangetic plain is less marked to-day. Pressure is highest on the Eastern coast. North-westerly winds prevail north of Bengal and Assam; South-easterly winds in Madras and Vizagapatam, and variable elsewhere. Fresh winds at False Point and Sauger Island, and in Goa light generally. Skies are overcast at Darjeeling. It is somewhat cloudy in the Punjab, Western districts and the N. W. P. clear; elsewhere the air is much drier. In Behar, Central Provinces, and Chota Nagpore the temperature has fallen; in the Western parts, N.W.-P., and parts of Madras, Cuttack, and Dhubri, it has risen generally. Thunder and dust-storms with rain and hail have occurred in the N.W. P. Rain to-day—at Cuttack and Secunderabad 1 inch, and Allahabad and Agra $\frac{1}{2}$ inch.

Editorial Notes.

MR. J. A. BAUER states that he finds quicksilver to be a perfect preventive of phylloxera. The quicksilver is finely comminuted with a dry clay, so that no globules of the metal can be detected by a magnifying glass; this is added to the soil around the roots of the vine, half an ounce of mercury being the proper quantity to be applied to each vine. The cost of treating an extensive vineyard by this process would therefore be considerable.

A CONTEMPORARY, having been asked whether "smut" grows on wheat and whether placing the seed wheat in brine will prevent the disease, says that are three diseases common to wheat which look much alike—*Uredo caries* usually known as "blight," "bunt," or "brand"—in this disease the interior of the grain is filled with spores of disagreeable odor. Pickling is resorted to in order to kill the germs of this variety of fungus. One pound of cupric sulphate (blue vitriol) is allowed to every four bushels of seed, dissolved in sufficient water to wet all the grain in turning; *Uredo segetum*, "blackhead," or "smut"—Grain is converted into a mass of black spores, but these wash off before harvest and do not injure the sample; *Puccinia graminis*, "mould," or "mildew"—it is now placed beyond doubt that this is one stage in the life-history of the fungus, of which the "barberry blight" (*acidium berberidis*) is another.

appears on the leaves of the barberry as the yellow spots known as "cluster cups," and the "rust" (*trichobasis rubigo-vera*) is another. It is most common in moist seasons and on rank crops. All barberry plants should be taken out of hedges, etc., so as to reduce the chance of propagation. Brine is of comparatively little value; at least by practical test we could find no benefit accruing from its use. Sulphate of copper (blue stone), however, almost a specific.

THE following is the substance of an address delivered by Sir J. B. Lawes, on the rotation of crops, at an adjourned discussion on the Rothamsted experiment at the Newcastle Farmers' Club meeting:—Looking at agriculture from the point

of view of a chemist only, there is nothing more puzzling than the fact that a wheat crop, following a crop of clover which has been twice mown for hay, may be as large as the wheat following the clover fed upon the land. The hay contained sufficient manure ingredients to grow several crops of wheat, while the sheep feeding on the clover returned to the land by far the larger amount of these manure ingredients. The two portions of the field must, therefore, be in different degrees of fertility. Why, then, should not the crops of wheat also be different? The only possible explanation must be either that the season will not permit of a larger crop being grown, or that the manure deposited by the sheep had entered into some insoluble compounds with the soil, and had not yet assumed that active form which could influence growth of the wheat. It is quite probable that the nitrogen removed in the clover hay would amount to 100 lbs. per acre. We have only to consider what would be the effect of applying 600 lbs. nitrate of soda per acre to the wheat, to satisfy ourselves how inactive the manure from the sheep must be. The object of these remarks is to show that in all cases where animal and vegetable manures are employed on the land, they enter into various combinations with the soil; some becoming the food of plants in short periods of time, while others only become available after long periods have elapsed. It would also appear to be almost certain that while some portion of such manures becomes the food of one class of plants, others can only be recovered when a different class of plants are grown. In our rotation experiment at Rothamsted, twenty-four years elapsed between the two clover crops. Every four years the root crop was manured with 2,000 lbs. of rape cake, phosphates, potash, and ammonia, and the whole of the bulbs and leaves were carried away, as well as the wheat, barley, and beans; in fact we did everything in our power to get out of the land the whole of the manure that we had put in. Our efforts, however, were not crowned with success, and a clover crop grown at the end of the 21st season, with a second clover crop grown eight years afterwards, revealed to us what a mass of fertility had accumulated in the soil, which neither the wheat, barley, beans, or roots could get hold of. Eight tons of clover hay per acre was taken off in the two years. It is evident that the ingredients taken up by the clover could not be food for the other crops, as the wheat after the clover was better than the wheat after the fallow where no clover was grown, and it is absolutely certain that upon the land—which grows wheat, barley, and roots with a fallow instead of clover—the manure ingredients have largely accumulated, and will continue to accumulate until some deep-rooted leguminous plant such as red clover, sainfoin, or lucerne, taps the mine. That these accumulations are in a great measure due to the manure used, is quite evident from the fact that upon the unmanured land very much smaller crops were obtained; we are not yet, however, in a position to explain the exact nature of the accumulations. We have recently carried our analysis of the soil of this field to the depth of nine feet. The ingredients, however, which we are in search of—although large and of great importance in a crop of clover—are apparently of too minute a nature for us to detect when spread over the area of an acre of land nine feet in depth and weighing about 36 million lbs. Whatever the explanation may be, we have the fact that a rotation of crops is an economical process for using up the ingredients found in the soil, as well as those applied in manures. If, then, we assign to the leguminous plants the office of collecting and utilising waste products, we

may call the cereal crops the great consumers and wasters of nitric acid, as a certain amount of weeds always grows up under the protection of the corn crops. It is part of the function of a root crop to prepare the land for future corn crops. The frequent stirring which takes place during summer and autumn—when the nitrification of the soil is most active—not only furnishes the roots with nitrogen, but also brings into growth and at the same time destroys the weeds.

.

DR. H. ZERENER is the discoverer of a substance called the Antimerulion, which can be used either in a liquid or dry state for the protection of wood and other materials from rot, mouldiness, fungus, white-ants, &c. The invention has been patented in Germany and Austro-Hungary, and the inventor received a diploma of honour at Magdeburg in 1880, and a prize medal at Braunschweig in 1881. Judging from the testimonials published, the Antimerulion seems to be much appreciated on the Continent and also in Bombay where there is an agency for its sale. If it would prevent the destructive ravages of white-ants, it would be hailed as a blessing by every house-owner and householder in the East.

.

A HOME contemporary writing on the subject of Indian and American Silver, says that President Cleveland's inaugural address at Washington has been received with general satisfaction. Unfortunately, however, it contained one intimation which may possess grave consequences for the Indian Empire. Though the President only hinted in a guarded way at a possible suspension of the Silver Coinage Act, he is well known to entertain very strong opinions as to its necessity. And this, in the interests of the United States, is perfectly demonstrable. Under the existing Silver Coinage Act the American Government is bound to coin nearly five million sterling pounds of silver a year. Thirty-seven millions in silver dollars has now actually been struck. Of this only nine millions is in circulation; the rest is locked up in the Treasury vaults. In order to avoid the natural consequences of this condition of affairs the policy of issuing silver certificates was introduced, and twenty millions in certificate paper circulates on a nominal equality with gold. The equality is strictly nominal; in the last few years both silver dollars and certificate paper have steadily been depreciating. Unless American finance is to fall into chaos, this process of depreciation must be arrested, and the only way to effect this is by suspending the Silver Coinage Act. When this is done, obviously five millions a year of silver must find a market elsewhere. Unless the Indian Government declines to keep its Mint open as now, the liberated silver will naturally stream into India. As India already pays twenty millions a year interest and military charges due entirely in gold, with an increasing addition to this liability owing to the normal fall in silver, and as flagrant injustice is inflicted on Anglo-Indian remitters to this country, such a prospect is alarming. It may, however, oblige administrators to address themselves to a difficulty which they have shirked on account of its gradual development. Unluckily financiers are by no means agreed, and while they wrangle, the disaster may occur. It is not impossible, however, that the bimetalism of the Strachey's may now secure serious attention, and perhaps in the reform of her currency India may owe yet another benefit to the financial genius of the two brothers.

.

THE Government of New Zealand are doing their best to encourage the establishment of a beet sugar industry even by the offer of a bonus. Up to the end of June 1884, an offer remained open of £1,000 for the first 125 tons of sugar manufactured from beet. Nothing came of it, and it is now announced that the Colonial Treasurer will pay out of the Consolidated Fund a bonus of one half-penny per pound to the person producing the first 1,000 tons of sugar from beet or sorghum. A little calculation will show that this is slightly more than half the value of the previous offer. For the first fifteen years, however, from January, 1885, no duty by way of excise is to be paid, while the present import duty of one half-penny per pound continues; and if the import duty is increased, the excise duty is always to be one halfpenny less. On the other hand, if the import duty is reduced or removed, a bonus

equivalent is to be paid. These terms, it must be admitted, while not equal to the former, are still very favourable; and it remains to be seen whether some enterprising capitalists, either here or in the Colony, will be prepared, in the present unsatisfactory condition of the sugar market, to take advantage of them. The same writer goes on to point out that in continental beet-growing countries, the industry is only rendered profitable by the bounty. In Germany eighteen-pence per day of eleven hours, together with potatoes, light, and lodging, is all that is given to the men working in the sugar factories. This is even a long way below West Indian rates. But even with this advantage the profit of £5 12s. 6d. per morgen—six-tenths of an English acre on the beet, divided over the whole area of cultivation, gives only an average all over of 37s 6d per morgen, or a sum about equal to the rent paid. At the present time the price of sugar is £4 6s. 4d. per ton under the cost of production, and when it is remembered that beet sugar must be sold as made, that it suffers heavily from an increase of glucose if stored, it will readily be acknowledged that the cultivation of beet in New Zealand is likely to be attended with considerable risk so long as the continental bounty system exists.

.

A CORRESPONDENT writing to a contemporary on the value of corn fodder says:—"Farmers in general do not realize the value of corn fodder as a winter food for cattle. The manner of feeding it has a great deal to do with its value, for when cattle are turned into the corn field after the corn is husked, they will eat but a little and trample down nearly all of it, and this is the true nature of cattle, for even in good pasture they will eat a little in one spot, and walk on, eating as they go. This will of course play havoc in a corn field, and over half of the fodder will be trampled under foot, while if the fodder is worked up with a cutter and fed in the stable they will eat all of it and seem to relish it, and the extra trouble and expense of cutting it is amply paid for by both the cheapness of the food, and how nicely the animals thrive on it. Prior to the winter of 1882 I had been feeding nothing but hay, but that winter the price of hay was so high I thought I would look for some cheaper feed and concluded to try corn fodder. The loft, which is a very large one, was filled with the long fodder. It was then put down through holes in the loft floor and fed to the cows in their feeding troughs. The holes in the loft floor were designed to put hay through, and were not large enough to put the long stalks through easily, and consequently made very awkward handling. The cows of course would not eat the largest stalks, but would pick off the leaves and tops, and what was left had to be carried out daily, and before spring we had an immense pile of stalks outside the barn. For all this was an awkward way of feeding, the cost was so much less than with hay, we intended feeding it again the following winter, but hit upon a much more convenient method of handling it. The fodder was cut up fine and fed to the cattle in baskets. It made a very clean food, easier to handle than hay, and we were very well pleased with it. Our cattle, 80 in number, had nothing but this cut fodder, with a small allowance of grain, all winter. They ate it up clean and thrived well upon it, coming out in the spring in excellent condition. The next summer, about the 1st of July, we planted several acres of corn in drills, about three feet apart, and rather thick in the drills, our object being to have green fodder to feed to the cattle during August and September, when pasture is always dry and scant, and as it was unusually dry that year, the fodder, of which we had a large yield, made an excellent substitute to take the place of grass."

.

THE Celestial Empire has been a sealed book to the world from time immemorial. The jealousy with which the presence of a "barbarian" among the people of the Flowery Land is regarded, precludes the idea of its ever being opened up to European enterprise. Now and again, however, a traveller more daring than his brethren, ignoring his personal safety, has managed to penetrate into the distant provinces of the Empire, and enlightened the world in regard to its natural productions, and the habits and manners of the inhabitants. Mr. Hosie, of the consular staff in China, has just rendered great service in exploring a remote section of the land, and the narrative of his journey through Central Sou-ch'uan will be

read with great pleasure by all classes of readers, especially by those who are interested in the development of a new industry. The object of Mr. Hosie's mission was to make inquiries regarding the nature and economic history of the insect wax which is so extensively used to make candles, though comparatively little of it is exported to Europe. The insects which were the special object of Mr. Hosie's solicitude are produced in the galls found in one species of trees. After escaping from these excrescences, they deposit their cerous secretion on the leaves of another, to which they are carried long distances by porters, who travel at a rapid pace over mountain and valley and river, terrified lest the precious freight, by escaping from their nests, should nullify the entire purpose of what Mr. Baber has described as their headlong flights. The first coating of the wax on the boughs and twigs has been compared to a layer of quinine. This deposit gets thicker and thicker, until after from ninety to a hundred days the wax has attained a thickness of about a quarter of an inch, the period varying according to the region in which the operation goes on, and the character of the season. Then, the insects having exhausted themselves, the branches are lopped off, and as much of the incrustation as possible removed by hand. This is placed in an iron pot, with water, and the wax rising to the surface at melting point is skimmed off and placed in round moulds, whence it emerges as the white wax of commerce. A second quality is obtained by boiling the twigs, and a third by placing the residuum of dead insects in a bag, and squeezing them until they have given up the last drop of their precious fluid. Finally, as a Chinaman is the thriftiest of the human race, the crushed pulp is used to feed the pigs, which fatten into that mellow-flavoured pork so dearly prized by the Sinitic epicure. This wax, which varies greatly in price according to the vicissitudes of the seasons and the consequent mishaps of the insect-farmers, is so hard that, while tallow melts at ninety-five degrees, one hundred and sixty can be reached before the cerous excretion which Mr. Hosie was sent to study shows any symptoms of giving way. Hence, in Cheungking, a portion of it is mixed with ordinary tallow, to give the latter a firm consistency, and the candles of this alloy are dipped in melted white wax, which imparts to them a harder sheathing, and prevents the "dips" from "guttering," or running over when they are lighted. It is, therefore, clear that it is a product of which a great deal more ought to be made, and now that the Kew authorities have the subject in hand, with specimens of the different trees on which the insects live, it is to be hoped that they may be duly introduced here and in Australia, where they may reach greater perfection than in their native land.

.

DR. H. F. CARRIET, Superintendent of the Illinois State Central Hospital for the Insane, at Jacksonville, Illinois, in his official report of the management of the institution, includes the following in regard to the feeding of ensilage to the cows kept to supply the institution with milk:—In the first year's experiment we were not as successful in preserving the ensilage as we have since been, by reason of moisture passing through the brick walls. On opening our first pit we found about six inches on top mouldy. We lined up the walls with boards, and have since put about a foot of straw on top of the ensilage before covering with plank, and our success in preserving the fodder has, since the first year, been nearly perfect; we had ensilage enough, both last winter and the winter before, to feed our cows for about three months. Commencing about the middle of December we fed from forty to fifty pounds per day, or rather twenty or twenty-five pounds twice a day, with two quarts of bran and one quart of cornmeal; the cows ate it well and were even greedy for it. This was fed morning and night, and a feed of hay given at noon. Both seasons the cattle have come out looking fatter and in better condition in the spring than even before. The milk and cream more nearly resemble grass milk both in look and taste. Our cows give more milk when fed on ensilage than when fed on hay, with the same amount of grain; as evidence of this, our cows fell off five gallons of milk per day in three days after the ensilage was exhausted, and this was not caused by any change of temperature or severe storms. These, then, are some of the conclusions we have come to, without, of course, paying enough

attention to the subject to make them of much scientific value, but some of these may do to put down as facts, *viz.*—That from sixteen to eighteen tons of green corn is about the average yield of one acre; that the feeding value of this fodder, ensilaged, is two and-a-half to three tons to one of hay; that cattle do better and will gain more in weight when fed on hay; that cows will give more milk, and the cream and butter will be more like grass butter when fed on ensilage; that calves do exceedingly well when fed on it. In short, we believe in ensilage, and have put down 100 tons again this season, but we have never used anything but corn for this purpose."

.

THE statistician in the Department of Agriculture, America, delivered an able address at the late Philadelphia meeting of the American Association for the Advancement of Science before the section of economic science and statistics. What he undertook to show were the following three propositions. And it would be well if our administrators would ponder over the remarks made by him in this connexion. He said:—
"The folly of attempting to 'feed the nations of the earth,' and neglecting the organization of all constructive forces and the development of the highest skill in production. 2nd, That every nation must be practically self-supporting, making possibly a few exchanges from an occasional surplus for a few luxuries that are unessential. 3rd, The consumption of the United States is the main stimulus of its production at the present time, and will be in the future. It has been the fashion among publicists and legislators to talk boastfully of our ability to transport the raw products of agriculture across seas to other continents for the food supply of the nations of the world. It is thoughtless talk, uttered under the inspiration of our emblematic spread-eagle, that boastful bird of the nation, and unworthy of intelligent and thoughtful citizens. It is folly, born of ignorance, to talk of subsisting large masses of the population of the world after supplying the wants of our own people."

.

"It is true that our production has advanced with wonderful strides. While population doubled in twenty-seven years, the wheat area doubled in fifteen; there were four millions of farms in 1880, and but two millions in 1860. The maize crop of one year is equal to the product of four years in Europe. The supply of wheat per capita was only 4.33 bushels in 1849, 5.5 in 1859, 7.46 in 1869, and 9.2 in 1879. We might produce 20 bushels per capita, but it would be folly to do it. The area in wheat is now 38,600,000 acres, and 12,000,000 acres are cultivated in excess of the wants of the country, the produce of which must be sold abroad, mainly in Liverpool, in competition with the grain of Russia, of South America, of Australia, and of India. It is sent 1,500 miles by land and 3,500 miles by sea, and from California more than half round the world, to compete with the half-civilized fellahs of Egypt and the slavish ryots of India. It is a competition unworthy of American freemen, and utterly unnecessary, being caused by bad calculation in the distribution of crop areas, for while we export one-third of the wheat production, we import one-seventh of all the barley consumption, and \$100,000,000 worth of sugar at foreign valuation, which brings \$150,000,000 in our local markets in addition to the costs and profits of refining here. This inequality of production is the result of temporary conditions, which, it is hoped, the good sense and correct judgment of farmers will remedy in the early future. The pioneer settler is far less a farmer than a speculator. At present he is engaged in a land speculation, appropriating acres from an unoccupied domain to bequeath to posterity, possibly a little reduced in productiveness, but certainly largely enhanced in price. And he finds it convenient to grow wheat year after year, till the weeds choke out all growth, with little labor and no cultivation, to get the ready cash with which to construct houses and barns, build fences, buy ploughs and reapers, and more cheap land. At a later day the pioneer, or his successor, will be quite as progressive as the advanced cultivator of the older settlements."

.

"I do not say that we may not produce a surplus of food sufficient to feed two or three small nations of Europe, but that

it would be both impolitic and unprofitable to do it. We have both the land and the labor, but prefer to have a wiser distribution of labor in production. Doubtless our customers in Europe would find it profitable if unequal distribution of productive effort should produce a great surplus of cotton, wheat, maize, or meat. Not many years have elapsed since cotton-growers were compelled to accept \$45,000,000 less for a crop of four and-a-quarter million bales than they received for the preceding crop of three million bales. Young Jonathan wishes it to be understood that he is quite too 'cute' to cultivate a continent exclusively for the benefit of outsiders; he is not yet so philanthropic as to accept meekly all the work, and give others all the profits. He is willing to relegate to his friends across the large water all the fame and fortune that comes from that sort of philanthropy.

.

"THE facts of industry and wealth, in the history of nations, show that accumulation, thrift, national wealth, do not depend on mere numbers, as one might suppose from a careless reading of political economy. The old idea that population enhances prices is at best a half truth. It is industry rather than population that creates wealth. Paupers do not enhance prices, nor idiots nor tramps cause a rise of 'rent.' The increment is proportionate, not to numbers, but to productive forces in action, degree in skill, persistence in labor. So labor that is inharmonious and unequal in its distribution among the industries is unremunerative. If nearly all workers are in agriculture, there may be abundance of food, and but few other comforts or appliances of civilization, and little money to procure any. Agricultural nations are proverbially poor. In India 70 per cent are engaged in agriculture, yet its products have been estimated at a value of \$8 per capita; in this country 44 per cent are so engaged, and agricultural production averages \$64 for every man, woman, and child of the population. So it is everywhere in Europe as well as in less favored quarters of the globe. Should we so unequally distribute labor as to be compelled to sell grain to buy dry goods, there is a bar to the disposal of a large surplus in the fact that few nations can afford to buy, or pay for if bought, except to a very limited extent. Fifteen years ago, when our export of grain was far less than at present, less than three per cent of our wheat surplus went to all other countries exclusive of Great Britain and her dependencies.

.

"AGAIN, while our agricultural surplus is greater than that of any other country on earth, it is insignificant compared with the volume of our consumption. We exported in 1883 products valued at three hundred and sixty-two million dollars, and the same year had to pay from this sum two hundred and forty millions for food and drink imported, besides large additional sums for transportation and commission. When we remember that these exports are reckoned in sea-board prices, and that farm prices are only half or two-thirds as much, the difference between shipments and receipts is narrowed down to a sum that is small, if not insignificant, compared with the value of the home consumption. After paying for imports of food and beverages with exports, it is found that only 2 or 3 per cent of a net surplus of material for subsistence is left, and that is an exceptionally large national showing. Other countries balance far more nicely their little exchanges of food products. Nations must be independent in the matter of subsistence or risk their very existence. We cannot depend on Europe for a market for our farm products. There must be such distribution of labor here that the farmer can get a fair price for his productions without hawking them around the world to be eaten up by an army of carriers and forwarders. Our cotton is exceptional. We produce nearly two-thirds of all grown in the world, and find it profitable to supply fibre for the spindles of Europe. We consume a third, and shall, ere long, manufacture one-half, and should ultimately use two-thirds in domestic manufacture. But in cotton, in food products, and all other exports, the exportation is but one-twelfth of the production.

.

"RELATIVE to the second proposition, that every nation must be practically self-supporting, there need be little discussion.

It is a self-evident truth. Otherwise national bankruptcy would only be a question of time. But may not a nation be dependent on another for food, if an equivalent can be given in other merchandise? The facts of production and consumption show that few nations do, and very few dare, fail to produce a nearly full supply of all the essentials of food supply. I have the facts as to the principal nations of the world; there is no time here for their presentation, but they substantiate the fact that every nation makes a vigorous effort to produce its own food supplies.

There is one apparent exception. Great Britain has little land and many people, most of whom are making goods, selling and shipping them, steaming over all seas and trading over all lands, filling the small gaps that occur in the production of civilized nations, and furnishing cheap goods to the half-civilized and barbarous people. Only one-eighth of the people in occupations are engaged in farming industry, while 57 per cent are in industrial occupations. Five hundred years ago nearly all were employed in agriculture, and could only feed the people. Now 12.5 per cent only are so employed, numbering nearly or quite as many as at the former period, and yet these few are able to produce 60 per cent of the food required for all the people. If one half the area of Great Britain can thus supply six-tenths of the food required by the labor of an eighth of the workers, where can the continent of America send the raw products of its future agriculture for consumption?

.

"THE industrial policy of England tends to concentrate her manufactures, to scatter her farms to Africa, Australia, and America. She prefers to grow her meat in Montana and her wheat in Dakota, or in Australia or India. But, as I have said in a recent publication, this exception is more apparent than real. English capital owns lands, herds, flocks in other countries, and receives cotton, wool, meat, and grain as dividends. If the dividends of English capital in the United States should be made an offset to our heavy bills for exports of products of agriculture to Great Britain, there would be but a trifling balance of that trade in our favor. Great Britain has land enough to feed all its population, if applied to the production of food and cultivated to the height of its productive capacity. But Great Britain prefers to make cloth and build ships, to establish country seats, practise landscape gardening, and hold game preserves; to grow mutton in Australia, fence in the mountain parks of Colorado and Wyoming for beef production, and establish great granaries in Dakota. Land is too valuable for agriculture in England; its title-deed is held as a primogenital badge of respectability, not to say of nobility. Laborers are bidden to emigrate or starve, and tenant-farmers are willing to sacrifice their birth-right and their patrimony for a mess of English pottage or Scotch oatmeal to eke out continued meagre subsistence on their native soil. The world is henceforth England's farm, and her home agriculture must be sacrificed to the policy of underselling the manufactures of other nations—to the necessity for cheap food and low wages by which alone to make that policy practicable. We can produce a surplus by neglecting production in other directions, but we cannot sell, if produced beyond a limited quantity, and then only by accepting the prices that our customers choose to give.

.

"THIS brings me to the third proposition, that our own consumption furnishes the best stimulus to production. In some suggestions on the industrial economy of the country, entitled 'Farm and Factory,' I have said that the domestic trade of a country is always its principal commerce. In this country the foreign trade probably represents scarcely \$1 in \$20 of the grand volume of mercantile transactions. It might be less without the slightest inconvenience to a human being if the importer alone excepted. With an area bounded by the two great oceans of the globe, and touching the domain of everlasting ice on one side and that of tropical temperature on the other, there is little need to go beyond its boundaries for anything. This continental area includes a range of elevation occupied in agriculture of 7,000 feet, giving variety of climate and production without regard to latitude. North Carolina and New Hampshire have a range of 8,000 feet, and California

still greater difference of altitude. North Carolina produces rice and wheat, figs and apples, and supply both ice and sugar for its insidious yet popular potatoes of peach brandy. The productions of the United States range from lichens to lemons, and include the fruits of all zones, from gooseberries to guavas. With these resources of soil and sun, of coal, iron, of gold and silver, of water for transportation and for power, of mind and muscle, of skill and genius, how stupid the folly of desuetude, how abject the shame of inanity, how injurious the crime of idleness. To go thousands of miles for that which we can produce from our surplus labor would be burning the candle at both ends, and drifting into the darkness of national poverty. Our population doubled in 27 years from 1853. It will double again, it is estimated by Professor Elliott, in 30 years, in 1910. Assuming 35 years and 40 years for subsequent duplications, the population will be 400,000,000 in 100 years from the present date, or nearly one-third of the present population of the world, with a consuming power, there is reason to believe, of nearly half the world. This is the field, rather than a foreign one, which American agriculture is called to fill in production and distribution—a field broad enough to satisfy the largest ambition. Should it require two centuries instead of one to reach this enormous figure, the field would still be large enough to nearly monopolize the results of American labor. There is ground for belief that with a growing symmetry in our industrial development, with culture of brain and deftness of hand, there will advance, by equal steps, an agriculture replete with skill, abundant in yield, varied in production, and remunerative of labor beyond the present dream of the rural class. There are signs of such progress which should attain such fruition. The rate of advancement will depend much upon the intelligence and action of the farmers of America."

✱

A NEW YORK butter-maker gives the following rules for butter-making:—"Decide your line of dairying—butter, or cheese, or both. Select your cows according to the line of dairying chosen. Test each cow separately, and reject all not suited to your line of dairying, or that fail in quality or quantity of milk. Feed liberally, have pure water always accessible, and keep a mixture of equal parts of salt, ashes, and sulphur within reach of the cows. Be sure your stables are thoroughly ventilated, remove all droppings immediately, and freely use absorbents and deodorisers—such as sawdust, dry earth, or cut straw, never omitting a liberal use of plaster. Be scrupulously clean in every particular, both in keeping the cows and in milking and handling milk. By all means avoid exposure of the milk to the hot sun and to foul air. Air and cool your milk as fast as possible down to at least 70 degrees, if you carry it any distance to a factory or creamery. Do the same if you make it into cheese at home, though you need not go below 80 degrees if made up immediately. When the milk is kept over-night to be carried to a factory, the temperature should be reduced as low as 60 degrees. If milk is set at home for cream, the sooner it can be set after milking and the higher the temperature the better, as cream rises best, and almost wholly, while the temperature is falling. Never reduce the temperature below 40 degrees, as a lower temperature has a tendency to chill the product and injure its keeping quality, and it expands the water, rendering its relatively greater density less instead of decreasing it. To go 5 degrees below 40 degrees would have practically the same effect as raising the temperature 5 degrees, and to that extent retard the rising of the cream. Skim as soon as the cream is all up, or so much of it as you wish to take from the milk. Keep your cream, if not churned immediately, at a temperature of 64 degrees or below, but not below 48 degrees. Churn at such a temperature between 55 and 64 degrees as experience shows you is best. Conditions vary the temperature for churning. Stop the churning when the butter is in granules about the size of wheat kernels. Draw off the butter-milk and wash in clean water before gathering the butter, until the water runs clear. If one washing is in brine it is all the better, as brine coagulates the cheesy matter, which dissolves, and is then washed out. Salt to suit customers, using none but refined salt made for dairy

purposes. The best American salt is as good as any. Put up in such packages as are demanded by your market. If for long keeping, pack firkins, set in a cool, sweet place, and keep the butter covered with brine.

COCA: ITS SOURCE, CULTURE, &c.

A VERY interesting lecture was delivered by Dr. Bidie, M.B., C.I.E., at Madras on the 28th March last, on the value of the Coca leaf as a therapeutical agent, both in surgery and medicine. Dr. Bidie said that owing to the medicinal and other properties that it has been found to possess, it is likely to become of very great importance as a commercial product; and he went on to say that the substance known as coca consists of the dried leaves of a South American plant, known to botanists as *Erythroxylon Coca*; and that in Southern India there is a species which somewhat resembles the American one, viz. *E. monorynum*, which was formerly called *Sethia Indica*, and is common in Cuddapah and various other dry districts, where it is known as *Devadaru* and *Adani goranta*. He said that during the famine in Cuddapah, the starving people were found to be eating considerable quantities of the leaves of a shrub, some of which were sent to him for identification. Judging from their appearance, the leaves, which were rather dry and fibrous, did not seem likely to afford any nourishment, nor had they any special taste or flavour to commend them as a relish or condiment. They were found to belong to a species of the same genus as the South American coca, and he thought that, like it, they probably possessed the property of allaying hunger and staving off fatigue. No chemical examination had, so far as he knew, been made of the leaves of the *Devadaru* eaten by the famine-stricken people, but it was a curious coincidence that they should have been so used. Further enquiry may reveal that the Madras species contains some active principle allied to, or identical with, that of the American plant.

Botanically described, the *Erythroxylon Coca* is a native of the east of Peru and Bolivia. It belongs to the tribe *Erythroxylea* of the order *Linacee* or flax family, and its specific appellation, coca, according to Markham, is supposed to be derived from the native name, *koka* or *tree*, that is, the tree *par excellence*. Dr. Bidie said that it was now some time since the plant was introduced into the Madras Presidency direct from Kew, and also by Mr. Cross, when he paid his last visit to the Nilgiris, entrusted with some new species of cinchona. As seen here, and also in its native country, coca is a bushy shrub, with numerous smooth leaves of a beautiful golden green colour above, and paler and glaucous on the under-surface. The leaves are lanceolate or somewhat oval in shape, and tapering at the base towards the leaf-stalk. At the upper end they are blunt and emarginate with, when young, a little prickly-like process in the middle of the notch. The characteristic marks of the leaf are two arched raised lines on the back, which extend from the base to the apex—one on each side of the midrib—and enclose a space which is somewhat hollow and paler in colour than the rest of the surface. The flowers are small, on slender drooping stalks, and of a yellowish colour. The fruit is a pretty little drupe over one-fourth inch in length, of oblong ovoid shape, quite plump when green, but furrowed longitudinally when dry. It takes from a fortnight to three weeks to germinate in Madras, and is easily raised in pans containing a mixture of leaf mould and sand.

Dr. Bidie said that Coca was cultivated to a very large extent in Peru, Bolivia and Columbia, and also in parts of Brazil, the Argentine States, and other countries of South America. It is said by Bentley and Trimen, in their "Medical Plants," to thrive best in the moist mild climate, which exists at an elevation of from 2,000 to 5,000 feet above sea-level in the warm moist valleys of the eastern slopes of the Andes of Peru. But the coca plant in the Madras Presidency thrives very well at sea-level on the coast, but its culture would probably be found much easier and more successful at higher elevations, say, from 1,500 to 3,000 feet.

He went on to say that the commercial product known as coca, consists of the dried leaves, which are used as a mastic-

tory by the Peruvian Indians to give comfort and enjoyment, just as the betel leaf is chewed in India. Its history, he said, was peculiar. From time immemorial the inhabitants of countries on the Pacific side of America have used this leaf, and, according to Markham, the Peruvians still look upon it "with feelings of superstitious veneration." In the time of the Incas, the former rulers of the country, it was employed in sun-worship, and also in barter instead of money. After the Spanish conquest, some fanatical invaders proposed to proscribe its use and stop its culture, on the grounds that it fostered ancient superstitions and took away the Indians from other work. In 1569 the second Council of Lima condemned its use, because it was "a useless and pernicious leaf, and on account of the belief, stated to be entertained by the Indians, that the habit of chewing coca gave them strength, which is an illusion of the devil." About the same time the Spanish Government interfered with the cultivation, on account of the unhealthiness of that valley, in which the "cocaes" or plantations were situated. Subsequently, between 1570 and 1574, the Viceroy, Don Francisco Toledo, endeavoured, by various edicts, to regulate the industry, so as to protect the health of the Indian labourers, and to ensure their being properly paid. According to Bentley and Trimen, the total annual produce of coca in South America at the present day is probably not less than 40,000,000 lbs., which, estimating the value on an average at the low price of 1s. per lb., gives a total of £2,000,000 sterling. The great virtues ascribed to coca have from time to time attracted the attention of travellers, physicians, and chemists, but until quite lately its merits have, in Europe, been considered somewhat hypothetical. Now that the value of its alkaloid, as a medicinal agent, has been fully established, we may expect that further uses for it will be found, and that a demand for it will arise throughout the civilised world.

Dr. Bidie gave the following as the mode of culture in South America:—The coca plant in Peru is raised from seeds sown in a small nursery, generally protected from the direct rays of the sun by a thatched roof or rows of maize. Sowing commences in December and January, when the rains begin. After sowing, the seeds require to be regularly watered, and may be expected to come up in from two to three weeks. In the following year, when from 1½ to 2 feet high, they are transplanted to prepared ground in the plantation, generally in terraces, where they are placed in square holes about a foot deep, and with the sides supported by stones to keep the soil from falling in. Three or four are planted in each hole, and allowed to grow up together. In level ground they are planted in furrows separated by walls of earth, at the foot of each of which a row of plants is placed. The usual distance apart is eighteen inches each way; and the culture extends up the steep sides of the valleys, as high as 8,000 feet, where the mean temperature is 61 to 68 Fahr. "At the end of eighteen months the plants yield their first harvest, and continue to yield for upwards of forty years." The plants require to be very carefully weeded, and if the rains are favorable, three crops of leaves may be expected every year. The produce of an acre is estimated by Weddell at about 900 lbs. in a favorable season, but the average is doubtless less. The leaves should not be gathered till mature, at which time they are bright-green on the upper, yellowish green on the under, surface, break off easily when bent, and have an agreeable, and somewhat fragrant, smell. They must be collected separately and carefully so as not to injure the buds that produce the following crop, and to prevent their being torn or bruised, which would impair their commercial value. The harvest is greatest in a hot, moist situation, but the best flavoured leaves are said to come from plants growing in drier parts high upon the sides of the hills.

The green leaves, when picked, are carried in cloths or baskets to the drying yard, where they are spread out on woollen cloths or on floors formed of slate-slabs, and dried in the sun. Very great care requires to be exercised in the drying process, as, if dried too rapidly, they get shrivelled and brittle and lose their odour and green colour. On the other hand, if imperfectly dried, they get dark in colour and have a disagreeable odour and taste when packed. In small experiments in Madras, Dr. Bidie found it better to dry them on a table in an airy

room, and not in the sun. In some districts it is said the leaves, while yet green, are trodden down with the feet, so as to give them a delicate flavour. This may have the effect of producing a mild sort of fermentation in leaves which have been bruised. Well cured leaves are uncured, of fine green colour on the upper surface, and grayish beneath. They have a tea-like odour and pleasant taste, and produce a sense of warmth when chewed.

Badly-cured leaves are dark-coloured, less fragrant, and devoid of the warm feeling when chewed. When dried, the leaves are either stored in houses or packed in sacks of cloth (*costos*) lined with banana leaves, each of which weighs about 20 lbs. The size of the packages varies in different districts from 20 to 150 lbs. There can be no doubt that the Coca suffers in transit, or when long stored in bags, and that it would be a great improvement to pack it in like tin, or lead-lined chests, of tea. Shuttleworth in the *Pharmaceutical Journal*, Vol. VIII, p. 222, says that "in South America particular care is taken to procure the leaves in as fresh a state as possible, and many writers have ascribed the want of effect to the use of old leaves. I have no doubt but coca deteriorates by age, as will also tea and most medicinal plants; but I am certain that it does not become wholly inert if preserved with care." Dr. Squibb observes that "coca is well known to be a very sensitive and perishable drug;" and again, "very much like tea in this and other respects, it should be packed and transported with the same care and pains in leaded chests or in some equivalent package. It is very well known that tea, if managed, transported, handled and sold as coca, it would be nearly or quite worthless, and therefore coca, managed as the great mass of it is, must be nearly all of it comparatively worthless."

If coca grown in India is ever therefore to take an important place in the European market, it must be dried with great care, and packed so as to preserve its virtues. In South America not less than 8,000,000 of the inhabitants habitually chew the leaf, and deem it as much necessary as the people of this country consider the betel-nut. As, until within the last few months the consumption of coca for medicinal and other purposes has been small, it is probable that it will be some time before the supply grown in America overtakes the demand for it which has sprung up in Europe and elsewhere, owing to the wonderful anæsthetic action that the alkaloid made from it exercises, when applied to mucous membrane and other tissues of the body. This alkaloid, cocaine, was recently sold in London at prices ranging from 2s. 6d. to 4s. the grain, and when it is mentioned that the leaves do not on an average yield more than 0·2 per cent, it will be obvious that there is abundant room in the English market for additional importation of the leaf, and good prospects of liberal profits for the grower. It has also to be repeated that the leaf is very perishable. After being stored for five months in its native country, it is said to lose its flavour, and to become worthless. Supplies of the fresh article will always therefore be in demand.

With regard to the modes of using the coca leaf in South America, Dr. Bidie said that the Peruvian Indians masticate the coca in combination with the alkaline ashes of the stalk of the quinoa plant (*Chenopodium quinoastrum*). In other places, pulverised quicklime is used. In Brazil the leaves are first dried, and then reduced to powder in a wooden mortar along with the ashes of a plant. An Indian usually partakes of coca three times a day, and consumes altogether about three ounces of the leaves daily. As it is chewed, it emits a grateful fragrance and promotes the flow of saliva; and according to Markham, "its properties are to enable a greater amount of fatigue to be borne with less nourishment, and to prevent the occurrence of difficulty of respiration in ascending steep mountain sides." It is also sometimes infused like tea, and the beverage drunk; and Mr. Holmes, of the Pharmaceutical Society's Museum, he said, informed him that a nice liqueur is prepared from the fresh leaves in Bolivia. A fluid extract, prepared in South America from the fresh leaves, has for some time been imported into England.

As to its properties and uses, Dr. Bidie said that coca has long been regarded as a stimulant of the nervous system and a sustaining agent, and the poet Cowley, who lived in the middle of the 17th century, put the following words into the mouth

of an Indian Chief when addressing the heathen goddess Venus :—

"Our *Varlocha* first his *coca* sent
Endow'd with leaves of wondrous nourishment,
Whose juice succ'd in, and to the stomach ta'en
Long hunger and long labor can sustain ;
From which our faint and weary bodies find
More succour, more they clear the drooping mind
Than can your *Bacchus* and your *Oenanthe* joined.
The *Quitaita* with this provision stor'd
Can pass the vast and cloudy *Andes* o'er."

Dr. Mantegazzo of Florence, who visited Madras a few years ago, on a scientific expedition, always carried a supply of Coca wherever he went. He became acquainted with it while resident in South America, and carefully investigated its properties. According to him, when taken in excessive doses it causes delirium, hallucinations, and ultimately congestion of the brain. In full doses it stimulates the heart and respiration, and increases the temperature of the body. When chewed, as the natives do, or given in weak infusion, it promotes digestion. In larger doses it stimulates the nervous system, so that muscular exertion is easily undertaken. Mantegazzo recommends its use in a variety of diseases.

In 1876 Sir R. Christison, the veteran therapist, made some experiments with Coca on himself and the students attending his class. From these he arrived at the conclusion that "the chewing of Coca removes extreme fatigue and prevents it. Hunger and thirst are suspended ; but eventually appetite and digestion are unaffected. No injury whatever is sustained at the time or subsequently in occasional trials ; but I can say nothing of what may or may not happen if it be used habitually. From 60 to 90 grains are sufficient for one trial ; but some persons either require more, or are constitutionally proof against its restorative action. It has no effect on the mental faculties so far as my own observations go, except liberating them from the dulness and drowsiness which follow great bodily fatigue. I do not yet know its effect on mental fatigue purely. As to the several functions, it reduces the effect of severe protracted exercise in accelerating the pulse. It increases the saliva, which, however, may be no more than the effect of mastication. It does not diminish the perspiration so far as I can judge."

About the same time that these were obtained by the scientific observer in Edinburgh, a Mr. Dowdeswell, who had been experimenting with Coca in London, declared that the results of his investigations were negative. He said : "Without asserting that it is positively inert, it is concluded from these experiments that its action is so slight as to preclude the idea of its having any value, either therapeutically or popularly." This testimony, being so utterly opposed to the experience of other competent observers, and to the fact that Coca has been chewed from time immemorial, and is still used by millions of people in its native country, can only be explained by the supposition that Mr. Dowdeswell did not get the genuine article, or it may have been old and inert.

Dr. Bidie said that quite recently a well-known London firm sent him a sample of what they called Coca, in order that he might become familiar with the commercial aspect of the drug as now sold at home ; but, on examination, he found that it did not contain one leaf of *Erythroxylon Coca* ! But that Coca, as already stated by him, was a very perishable article, a fact which is sufficient to explain much of the contradictory evidence in existence regarding its refreshing and sustaining effect. A few years ago a number of men connected with the Toronto Lacrosse Club in Canada, resolved to try the sustaining effect of Coca in this game which involves violent bodily exertion. At the beginning of every match a dose, ranging from 1 to 1½ drs. of the leaves, was served out to each man, which was chewed gradually during the game. The trial extended over nearly a year and a-half, and the majority of the experimenters were "strongly in favour of Coca—some most enthusiastically so—while two or three out of the number remained indifferent, having derived no direct or apparent advantage from its use."

This is only what might be expected, as tea, coffee and tobacco produce, owing to idiosyncrasy or difference of insensi-

tiveness, very different effects both in quality and degree in different individuals. Quite recently Dr. Caudwell, of Westminster Hospital, London, tried on himself the effects of large doses of Coca. He first used the valoid, a fluid extract equivalent to its weight of the leaves, and increased the doses gradually from 2 drs. to 2 ozs. The latter dose produced giddiness and unsteadiness of gait for about ten minutes, and then a general sensation of comfort with considerable mental excitement, and ability to read steadily for many hours, and to keep awake all night. He next tried the alkaloid Cocaine, increasing the amount from half a grain to 5 grains. The latter dose caused toxic symptoms, and produced dilatation of the pupils, which lasted for six hours. So far as is known at present, Coca exerts a double action, being a cerebral sedative in small doses, and a cerebral stimulant in large. But it is unnecessary to pursue this aspect of the subject further. The fact that 40,000,000 lbs. of Coca are consumed annually by the inhabitants of South America, is itself suggestive and conclusive ; and when to this are added the results of independent investigations and our recent knowledge of the action of the alkaloid Cocaine, we can have no hesitation in accepting Coca as an article quite as useful to humanity as either tea or coffee, and destined, as far as present appearances go, to become infinitely more so.

Dr. Bidie went on to say that the existence of an alkaloid in the leaves of the Coca plant was suggested as early as 1853, by Wackenroder and Johnston, and in 1857 Dr. E. Gadeke, a German, succeeded in isolating it, but not being able to satisfy himself as to its identity with *Theine*, the alkaloid of tea, he provisionally named it "*Erythroxylon*." But it was not till 1860 that the physical characters of the alkaloid were fully ascertained, and the honour of their description belong to Niemann who called the substance "Cocaine." Somewhat later, Lossen found in the leaves another base, which he termed "Hygrin," and which is volatile and apparently inert. The other chief constituents of Coca are *Ergonin*, *Cocotannin* and a peculiar wax. Cocaine crystallises in small colourless and inodorous prisms, which are slightly soluble in water, more so in alcohol, and very soluble in ether. It has a strong alkaline re-action, a slightly bitter taste, and produces upon the tongue a temporary but almost complete insensibility at the point of contact.

An attempt has been made to change the designation of the alkaloid to *Cineine*, but as that would be at variance with the botanical specific name, the alteration seems undesirable. The chemical formula for Cocaine is C₁₇H₂₁N, No. 4, so that it is very nearly allied in its composition to Atropine and Dyturine. The most useful salts of Cocaine are the hydrochlorate, the citrate, and salicylate. At present the hydrochlorate is the favourite preparation. It is defined as a white crystalline powder of weakly acid re-action, with a somewhat bitter taste, and producing on the tongue a temporary characteristic insensibility. When heated upon platinum foil, it should leave no residue, and it ought to dissolve in double its weight of cold water, and not become coloured in contact with mineral acids. It also dissolves easily in alcohol.

Although the local anæsthetic properties of Cocaine were recognised so long ago as 1860, curious to say no practical use was, until quite recently, made of the discovery. This was all the more remarkable, inasmuch as Dr. Hughes Bennett, in 1874, found, on investigating the action of Cocaine on frogs and other animals, that it "exerted its influence on the sensory nerves, and that the nerve-endings in the skin and the mucous membranes were rendered inexcitable, apart from any action or influence on the nervous centres." The credit of the practical application of the anæsthetic properties of Cocaine belongs to Dr. Kollar, a young physician of Vienna. He suggested, in the course of last year, its application to the eye for producing temporary insensibility during operations on that most sensitive organ, and the momentous value of the discovery was at once recognized all over Europe and America.

That since then Cocaine has received an amount of attention which shows the high rank it is likely to attain as a therapeutic agent. Professor Kuapp, who was one of the first to carry out experiments as to the effects of Cocaine on the eye, found that when a 4 per cent solution is applied, the pupil begins

to dilate in from ten to twenty minutes, attains its maximum in from thirty to forty-five minutes, remains stationary for about half-an-hour, and then slowly diminishes. The reduction of sensibility begins in about three minutes after the application of the solution, increases from ten to twenty minutes, and is over in about half-an-hour. When applied in appropriate quantity to the eye, it completely obliterates sensation for the time being, and renders it absolutely insensible to pain, and it neither causes irritation, induces injurious re-action, nor interferes with the vitality of the tissues.

But it is not only in diseases of the eye that Cocaine is useful, as it acts equally on the mucous membranes of the mouth, pharynx, larynx, nose, trachea, &c. It also acts quickly through wounds or abraded surfaces, but is slowly absorbed by the skin. When injected hypodermically, it acts efficiently as a nervine in doses of half a grain. The dose internally of Cocaine is from one-half to 2 grains, and, unless in large doses, it does not manifest any toxic action. Dr. Bidie explained that in a popular lecture like the present it was not necessary, nor would it be appropriate, for him to say more as to the medicinal properties of this new remedy. Although its therapeutical value was discovered only a few months ago, its fame has already extended to the utmost bounds of civilisation, and the only barriers to its extended use are its scarcity and costliness.

He said it was a very curious fact, that about three-fourths of the human race consume, as beverages or otherwise, five different articles, all of which have exactly the same active principle, *viz.*, an alkaloid called *Theine*, which received its name from having been first discovered in tea. The substances referred to are tea, coffee, mate or Paraguay tea, guarana and Kola nut, and so far as we know, these are the only plants of the whole vegetable kingdom that contain *Theine*. But we now hope that we have discovered a rival to the *Theine* group in Coca, as it possesses powers that will render it still more useful as a beverage. For those who have much mental work to get through, Coca will prove a stimulating, soothing and refreshing beverage; and to those having to undergo much physical exertion, it will be found of great value from its sustaining, recuperative, and refreshing qualities.

He said he believed we had found in it the popular beverage of the future, that which our testotal friends have been so long searching for, *viz.*, an article that will, in physiological utility and popular estimation, take the place of alcoholic drinks. Tea and other substances, of which the active principle is *Theine*, increase the waste of the body, especially when the amount of food is insufficient, whereas Cocaine has a conservative and sustaining influence under similar circumstances. Again, tea is sometimes taken to prevent sleep, and Coca, in full doses, has the same effect, while in moderate doses it induces sleep, and will be found specially useful in insomnia as the result of overwork. We have thus, he said, a very useful agent in this substance, and what is now chiefly wanted is the discovery of some method of preparing it that will make its use as easy as that of tea or coffee, and the resulting preparation as grateful and acceptable to the million.

Mr. Holmes, Curator of the Pharmaceutical Society's Museum, wrote to Dr. Bidie: "It is a useful digestive and tonic, and if the leaf could be dried in the form of tea, so as to be used like coffee, as an after-dinner beverage, and flavoured like the finest Chinese tea either by a carefully watched fermentation before drying, or by flavouring with *Jasminum sambac*, rose flowers, *Olea fragrans*, *Aglaia odorata*, or any other delicate perfume that would mask the flavour of Coca, it might be introduced over here."

He concluded his lecture by observing that it now only remained for the planter and chemist to devise some mode of preparation, that would render the substance acceptable as a dietetic beverage in Europe. A fluid extract which is now in use to a small extent, apparently retains all the active properties of Coca; but it is treated more as a drug than as a seductive and comforting luxury, and what we want is an article that will appeal to the palate of the many, just as tea and coffee do. As further uses are found for Cocaine, its consumption will increase, and if we also had a tea-like Coca, the demand for the leaves would be very large. The subject, he felt sure, only needs to be brought to the notice of our

enterprising planters to secure their attention, and if the culture of Coca can be made profitable, the South Indian planter will very soon take it up.

ON TEA.

A LATE number of the *Home and Colonial Mail* contains an interesting article, full of useful hints from a practical point of view to the tea-planter, contributed by one of their confrères who writes under the nom de plume of "Artemus." That he is an authority on the subject whose opinions will be entitled to consideration, would appear from the facts that he has had many years' experience as a planter, and he has been watching the market in London for two consecutive years. The following opening paragraph will disarm captious criticism. He says:—

"The very nature of my communication will, alas! compel me to tread upon the corns of prejudice in some quarters. This is, however, no ill-omened message for those who can appreciate large facts. On the contrary, if the industry is launched into fresh and vigorous life at the sacrifice of those who will not avail themselves of the new order of things, that price will be cheap, indeed. Let it be remembered, however, that the opinions I merely chronicle here are the growth of the time, and that to abuse the chronicler is about as pertinent as to attempt to stop the progress and results of these opinions by the mere repetition of *dustoor nichin*."

The first point to which he directs the attention of his readers is the "poor prices" from which the planters have had to suffer for many years past, and there are practically unlimited number of reasons for this undesirable state of things, each of which may be said to be owing to no fault on the planter's part, beyond the other causes for which the planter might be blamed. The writer is of opinion he has been hitherto guided for the most part by the accumulated experience of his former superiors, and the knowledge he has gained in the course of his management, and therefore he may be reasonably pardoned for any shortcoming in turning out the indifferent tea of which so much is heard now-a-days. His knowledge not having been equal to the requirements of the case, it is not to be wondered at that he should fail in some measure. The question now is what should he do in the future to avoid the shoals and quicksands upon which so many have been wrecked. In the first place the planter has trusted too much to chance, and therefore his success has hinged too much in the happy discovery, by mere accident of some particularly "good" method as judged merely by the bulk of the outturn, without taking into consideration the quality of the article manufactured. Next when under the pressure of turning out unwieldy quantities from single estates the planter threw aside the Chinese methods of manufacture, and with that the experience of centuries and launched out upon a new career, with what result is patent to the world. In regard to machinery we cannot do better than quote the words of "Artemus." He says:—

We adopted machinery and mechanical dryers, and changed the whole system of manufacture, and for a time have been elated at the boasted "progress." We experienced the great advantages of machinery, but we had not counted the cost, as in our sublime ignorance we did not reckon with deterioration, which we had carefully opened the door to without knowing how or in what direction. That door has to be closed. Do not suppose that I am blaming any machine, far from that. Machines are essential to our factories, but we must reorganise our system of manufacture to bring about the good results we obtained in the old "pinning" and *chulah* days; and before we reorganise our system we have yet to discover the scientific *raison d'être* for every detail necessary to our end in view—the production of perfect tea. We want no more dallying with science, no more spasmodic efforts—we want a scientific reason for the faith that will be in us when we can say: We can make good tea in all weathers. This grand aim is the only one that will satisfy the natural requirements of the case now that these are being recognised in the proper quarters. Proprietors are sick of excuses ancient and weather. Shareholders are asking why bad weather for manufacture is allowed to affect quality in these scientific days?—and there is more sense in this question than in many asked by their class. Provide the weather admits of properly matured leaf being gathered, that is as far as dependence upon the weather

should be allowed to affect the question. After that, quality and weather should be divorced. With the introduction of ensilage and harvest-saving machinery, this has been brought about in other crops; tea "manufacture" must be overhauled in its turn, and rule-of-thumb replaced by due attention to rules formulated in strict accord with the series of chemical actions, mechanical actions, &c., involved in the production of good tea.

Taking these facts into consideration, the writer very properly asks the question, what do planters know of the reasons of their various processes, and what do they know about the chemical cause of the effect they produce? In his opinion they know nothing; as instances he cites their view about fermentation which would amuse scientific men, and the practice hitherto observed of sending the juice flying in the rolling process under the impression they were increasing the strength of their teas! The produce of "perfect tea" depends not upon one but upon all the processes involved in the manufacture, each of which is a link in a complete chain of processes which science directs to one end, and which produces as a result that state of leaf in which all the elements of good tea are to be found. But perhaps as this would be too much to aim at all at once, the planter should confine himself to the production of good tea. Here the writer refers to the manipulation in the tea-house, which he defines "as dependent upon a scientifically arranged series of processes, whereby that state of tea in which shall be found all the elements of good tea, to the full power obtainable from the green leaf as brought to the tea house, is produced." The state of the weather being at present an important factor he goes minutely into the subject, and the following remarks will be found of great practical interest:—"By sending out chemists specially selected for the purpose to each important district, with all necessary appliances for fitting up special laboratories in well selected factories, we should institute a series of tests and analyses carried on daily during the manufacture at each stage for at least two seasons. These gentlemen should keep proper meteorological records from observations taken at least four times in the 24 hours, and full comparative notes as to the effects of the rain-fall, temperature, &c., &c., upon the leaf brought in, and upon the leaf under process of manufacture at each stage. To do this the comparison must be completed with daily analyses of tea made and notes upon the hydrometer readings in the tea house, and all other points bearing on the conditions ruling. Theoretically, doubtless, chemists could formulate instructions upon the salient points to be kept in view in preparing tea, but where the weather plays such an important part as at present, I doubt whether experimental scientific investigation, such as I have briefly hinted at above, is not absolutely necessary. Again, the thorough comprehension of the present mode of manufacture is necessary to the chemist before he can properly realise the present conditions and base his advice upon these—which is a very important point to be borne in mind, as his advice should aim at utilising as much as possible present appliances. Further, without local experience, how is he to discover where wastage occurs, at present, of such vital items as the volatile flavouring properties, or of the strength-giving tannic acid, and yet to the loss of this latter will in all probability be attributed the deterioration which of late years has been so noticeable. The chemists, eventually having satisfied themselves that they had mastered the scientific detail of tea manufacture, should go into committee, and produce a *Guide to Manufacture*, explaining therein the cause for each process, and the effect to be produced, with such suggestions as to overcoming atmospheric disadvantages as may be proper. Once people know what has to be provided for or provided against, the necessary means will not be long wanting. The tea-house men of the future would thus have the chance of learning their business and of advancing in their profession, being in possession of a reliable pointer indicating that road to improvement which is so exasperatingly closed to them at present. Of course as the climatic conditions ruling in one province are not identical with those of another, the rules proposed for Assam could not be safely followed at Dehra Doon, and *vice versa*. It would therefore be advisable to have such experiments tried in various parts of the continent of India suited to the varying climates of the provinces.

Miscellaneous Items.

THE probable outturn of the tea crop in Ceylon is estimated at 3,500,000 lbs. Many old coffee estates are now entirely under tea.

OWING to the water in the tanks at Bangalore having fallen very low, large quantities of fresh water fish are now obtainable in the bazaars at nominal prices.

THE Government of India concurs in the opinion expressed by the Government of Madras, that satisfactory progress has been made by the Madras Agricultural Department.

WE understand that Mr. A. Dowling, of Chittagong, is publishing a small work, entitled "Tea Notes," which should contain much profitable reading for planters and others interested in the tea industry.

WE learn that the Kurrachee Municipality have called upon the fishermen to discontinue salting and curing fish in the present locality. They are required to carry on their business at a considerable distance from the existing site. The fishermen object to this. We shall probably soon hear of a prosecution, when the legality of the requisition will be tested.

QUETTA is said to be looking its prettiest just now. The apricot and almond orchards in the valley are in full bloom, and the effect of the pinky-white cloudlike masses of blossom is very striking and pretty. Owing to the unusual amount of rain—nearly ten inches, two-thirds more than the average annual rainfall already this year—the zemindars are looking forward to bumper crops.

ALL the tanks at Aden are full to overflowing, thanks to exceptionally heavy rains; so the troops will enjoy during this hot weather an exceptionally liberal supply of water. The rains have caused some damage, as well as conferred a great benefit. At Shaikh Othman, the place lately acquired by the British, five miles inland, a number of houses have collapsed; and some salt-pans, recently opened by an Italian speculator at considerable expense, have been destroyed.

THE Rawul Pindie Annual Horse Fair was brought to a termination on Thursday evening, the 28th ultimo. The prizes were distributed by his Honor the Lieutenant-Governor of the Punjab. A large number of the Civil and Military officials were present, as were also the Maharaja of Puttiala, and the Nawab of Bahawalpore. The Bands of the Royal Irish Fusiliers and 21st Punjab Native Infantry were in attendance. Owing to the blustery and showery state of the weather, the usual tent-pegging, &c., did not take place. The show of horses, although perhaps not so numerous as anticipated, has been good as regards quality, and numerous remounts have been purchased.

WE like the suggestion that a special inquiry be ordered into the working of the Forest Act generally, and in the Thana district in particular. Surely Government have no objection to this course? An independent inquiry will show with what cruel injustice certain provisions of the Act have been applied, how popular interests have been trampled, and the feelings of a people very little removed from childhood in their rough simplicity outraged by the underlings of the Department. We have never heard a more touching protest than the poor Thanaites are in the habit of making—"Why don't you kill us and skin and bone us? Everything else you have done"! They go about in groups, praying for mercy. We are thankful the Bombay Association has taken up their cause.

COLONEL MONEY, an authority on tea cultivation, in a letter to a Ceylon paper, remarks:—"Looking at it from an Indian point of view, it is sad for India that Ceylon has proved such a good tea-field. But though, doubtless, your yield is very large per acre, and the quality of the tea very good, there is one point not proved yet, which Ceylon planters should not shut their eyes to. In India they give the plant rest, a holiday for three or four months, less in the plains, more in the hills, and it may be, nay, it is probable, this rest is a necessity. In Ceylon you pick more or less all the year round. Is this wise? Will the tea-plant stand it? I do not say it will *not*. Manure may do much to mitigate this evil. But the chance of a collapse should not be overlooked, and were I a tea-planter in Ceylon to-day, I would, in spite of the climate, which enabled me to pick all the year round, not do so. Take it all in all, during this last year, 1884, I must admit that Ceylon has in a measure beaten India in quality."

THE Bhundarees—dealers in toddy and toddy-spirit—of Bombay have forwarded a petition to the Viceroy, in which they state that in September last, they presented a petition to Lord Ripon, the then Viceroy, setting forth the grievances under which they had been labouring. In reply they received a telegram from the Finance Office, Calcutta, stating that their memorial was still under consideration, while about a month later, they were informed in a letter from the Revenue Department of the Bombay Government, that the Government of India had intimated that they declined to interfere with the orders passed by the local Government on the subject of the taxation and sale of toddy-spirit in the town and island of Bombay. The memorialists draw attention to what they think is an inconsistency, and beseech his Excellency to reconsider their case, because ten thousand families of toddy-drawers, who were hardly able to live from hand to mouth prior to the coming in force of the stringent arrangements, have been starving in consequence of their having been deprived of their means of subsistence.

"Sir,—You were kind enough to publish a short time ago a letter from me with a few remarks on grasses, in which reference was made to opinions held by Mr. F. de Laune on permanent pastures. Since then, through the kindness of a friend, I have his pamphlet on *Laying Down Land to Permanent Pastures*, and as the subject is one of great importance to a farming community like ours, perhaps you will allow me to make a few remarks on it. Mr. De Laune was a gentleman who, as he points out, first commenced farming 150 acres for pleasure, and then 900 acres more. He determined to lay it down in pasture in preference to arable farming. He, too, like all of us, was dissatisfied with results, and determined to find out the cause of failure. His observations and experiences are of great value. He begins, speaking of English farmers, by saying that few of them know the different grasses, and look upon one as being as good as another, and adds:—'It is generally, I might say invariably, alleged, and truly so, that newly formed pastures have been found to deteriorate greatly after the first two or three years.' This is very much the same here. How often does one observe puddocks which have been laid down a few years, grow little else than weeds. What are the causes? First, we have on clay lands want of drainage. A retentive subsoil holds water to such an extent as to swell, and leave the adventurous rootlets which push their way down to live in winter in stagnant water, with little or no air to breathe. Is it to be wondered at that they are sickly? What would drainage do? It would allow the water to pass through the subsoil and be carried off gradually, an ameliorated condition would set in, air would also have free access, and the roots of plants would gain a fresh livelihood by feeding on the nourishment contained in it. This condition of things is scarcely the same in England, where the cost of drainage is within the means of most. Here it is out of the question for some time to come. Mr. De Laune says:—'The use of short-lived grasses and biennial clovers, coupled with an inefficiency of proper seed, is the main cause of deterioration in new pastures after the first two or three years.' He then goes on to give those which in his experience, and from practical test and analysis are the best grasses:—'The five coarse grasses, valuable beyond all others for permanent pastures, are cocks-foot (*Dactylis glomerata*), meadow fescue (*Festuca pratensis*), and its ally tall fescue (*Festuca elatior*), timothy (*Phleum pratense*), and meadow fxtall (*Alopecurus pratensis*). These five grasses should form the bulk of all pastures on good soil, either for sheep or cattle. The finer or minor grasses are crested dogstail, hard fescue, rough meadow grass, florin, sheep's fescue, and golden oat grass. A meadow composed of the above would be perfect as regards grasses, assuming that the proper proportions were used, and would produce food for stock during nearly every month of the year. The clovers, which, however, should be used in much smaller proportions than the grasses, are permanent red clover, cow grass, aleyske,

and white or Dutch clover. Seeds of milfoil or yarrow ought never to be omitted.' Again: 'The grasses most pernicious to newly-formed pastures are first and principally rye-grass in all its varieties, and Yorkshire fog, or soft, woolly grass.' Now, everyone knows that at least three-fourths of our pastures consist of these two latter. Practically speaking, as far as we are concerned, most of these grasses are out of our reach. They have to be imported from England, and even then the percentage of seeds germinating is small, and the voyage out reduces that percentage so much that, until we can get them locally grown, they are too expensive to be thought of. As I pointed out in my former letter, however, we have two of the principal within our reach—viz., cocksfoot and timothy. The seeds of crested dogtail and yarrow do not suffer so much from the voyage, so a little of these might be included in our mixture. The percentage of germinating seeds in foxtail is only 20, which on an average is reduced by the voyage to five, so that the cost of one pound of that grass which would grow, assuming the cost to be one shilling—it is generally more—would be £1. Now for the test of analysis. The best authority we have is Sinclair, who was gardener to the Duke of Devonshire. His book, *Hortus & Amnicus Woburnensis*, was published, I think, at the end of last century, but the analysis of the different grasses was carried out by a man of eminence, Sir Humphrey Davy. I will give the result of their experiments in the three grasses, cocksfoot, timothy, and rye-grass. Cocksfoot, when cut on April 15, weighed at the rate of about 10,209lb. per acre, which afforded about 1,190lb. of nutritive matter. At the time of flowering, the green produce was equivalent to 27,905lb., which lost in drying nearly 16,045lb., and produced only 1,089lb. of nutritive extract. At the period of ripening its seed, a reduction in weight equal to 1,361lb. per acre, had taken place which yielded an increase in dry hay at the rate of 1,413lb. in nutritive extract—about 363lb. The advantages, however, were more than counter-balanced by a deficiency in the quantity of the aftermath. Timothy, grown in a clay loam, produced when flowering at the rate 40,837lb. of grass per acre, which lost 23,481lb., or little more than half its weight, in drying and its nutritive extract in the same period was equivalent to about 1,595lb. per acre. At the time of seed-ripening, no change worth mentioning had taken place in the weight of its green produce, but the loss in drying then only amounted to about 21,440lb., while the nutritive extract had increased to 3,689lb., which anomaly is of greater importance to the seed grower than to the grazier, as the increase is fully counter balanced by the deficiency of the aftermath. Rye grass, grown on a rich, brown loam, at the time of flowering was equivalent to about 7,827lb. of grass, 3,389lb. of hay, and 305lb. of nutritive extract per acre, and the proportional value which the grass at time of flowering bore to that of time of seed ripening was as 11 to 10, and to the grass of the aftermath as five to two.' Although these experiments were crude according to later ideas, they are sufficient to show how far behind rye grass is:—

	Lb. nutritive matter at time of flowering.	Lb. nutritive matter at time of seed-ripening.
Cocksfoot	1,089	1,452
Timothy	1,595	3,689
Rye grass	305	277

Whatever one's opinion may be of ryegrass, however, there is no doubt that under certain conditions, in this country it flourishes in an amazing way on such lands for instance as the Napier plains, or in the alluvial flat on our coast. From my own experience I am inclined to favour cocksfoot on dry hills, and timothy on wetter lands. On some fern hills I burnt, I sowed and harrowed cocksfoot, and there is as close a sward as I could wish, although it has been down eight years. On a piece of low-lying land with clay subsoil, I sowed 12lbs. of timothy nine years ago, and it is better now than ever it was. On another piece of similar land I sowed principally ryegrass, about six years ago, and the result is most unsatisfactory. On the other hand ryegrass, by the use of stimulants, may be made to grow more quickly than any other grass, owing to its shallow root. On Woodendean, the late Major Willis used 30wt. per acre of bones, and the following year 20wt. of superphosphate, and although the grass was very inferior before this, when he cut it for hay it threw an amazing crop—as heavy as any I ever saw, and the pasture is still good. The following is Mr. De Laune's opinion of cocksfoot:—'Cocksfoot is by far the most valuable of all grasses, because it grows on all soils; it produces the greatest amount of keep; it is the most nutritious grass, and seems to grow faster and stronger in extremes of weather, either wet or dry, than any other grass. There is, moreover, hardly any stage of its growth in which sheep do not eat it greedily, and its flower heads appear to me to be specially nutritious to all kinds of stock, young or old, in excessively wet weather.' Cocksfoot has no chance of seeding unless there is a great abundance of it and the stock are running light. It is often objected to as it is said that stock pull it up by the roots, but it will be observed that it is not the centre root but the side shoots which are lying on the ground. Cocksfoot is different from the other permanent grasses after being mown, and its long leaves may be invariably observed whenever it is present in a meadow after it has been mown for hay. On this account it is extremely objectionable for lawns. Timothy or crested dogtail commences to grow as early as cocksfoot in the spring, and bears feeding off remarkably well, as it seems to produce as heavy a crop in summer after having been fed off in the early part of May as it would have done had it not been touched. Like cocksfoot, it is never allowed to seed by stock, and its flower heads are extremely grateful when the seed is ripe to both old and young stock. This grass is much objected to by many on account of its apparent coarseness, but as all kinds of stock like it, there is no force in this objection. The aftermath of this grass does not appear so strong in growth as that of either foxtail or cocksfoot.

Crested Dogtail.—'When it abounds in too large a proportion, it does not do to lamb early, as the land will not yield early grass.' It will also be found that where stock fatten admirably chiefly on this grass about midsummer, they rapidly fall off if left in the pasture after the dogtail is ripe. 'Yarrow is a herb that sheep especially like, and however great may be the quantity in a meadow, it is rare to see it in blossom where sheep are. Cattle have not such a predilection for it as sheep, but before autumn comes it will be found closely eaten.' Of rye-grass, he says, in a paper read at Canterbury (England) before a farmers' club:—'The most important conclusion I have arrived at is the necessity of discontinuing to sow that popular grass, rye-grass, and of getting rid of it from our pastures. I have never been able to see that it has any merits beyond its early abundance and great capacity for bearing fertile seed. My own observation leads me to condemn it absolutely, but, in condemning it, I am aware that I have opposed to me some great modern authorities, amongst whom are Sir J. B. Lawes, in Hertfordshire, and Sir Kenneth Mackenzie, in Rosshire.' And again, 'It was only by constant and continuous observation that I arrived at the conclusion that it was the cause of so much evil, and I have learned to dislike its presence more than thistles. I assure you, gentlemen, I detest the sight of it.' Dr. Voelcker, chemist at the Royal Agricultural College, Cirencester, whom he calls 'one of the most scientific, and one of the most practical agriculturists in the world,' writes to him thus:—'Rye-grass is a very rank feeder, and gives the better kind of grasses and clovers a poor chance to grow well when it has once taken possession of the ground. In my opinion, the less rye-grass there is in the mixture of seeds intended for permanent pastures, the better will be the produce taking all things, quality as well as quantity, into account.' I lately read an American book on grasses by Mr. Flint. This writer spoke highly of cocksfoot, timothy, and red-top (*Agrostis vulgaris*), which is peculiar to America, but said that American farmers sowed down with timothy and red-top. Ryegrass, he says, does not find favour. You will see, I think, from all the foregoing that if we wish to have good pastures we must give up sowing ryegrass, which unfortunately for us, is what we have hitherto been depending on. As for myself, I shall, in the future, sow 20lb. of cocksfoot, 10lb. of timothy with some clovers, per acre, and, although I cannot expect to have such pastures as Mr. De Laune has at Shasted-court, still I am convinced that it will be a great improvement on those I have already sown. I should like to have added a few remarks upon turnips, and upon artificial manures, but I have already trespassed too much on your space. I hope to do so at some future time.—*Australasian*.

HOP BEER.

MY. DEAR "HUMMING BEE,"—Seeing under the above heading that you desire a receipt for making the same, I will endeavour to instruct your many readers upon the subject. I have observed that you kindly gave many receipts before, which, with ordinary intelligence, should have been sufficient. Permit me, however, to say that your last receipt, on the 7th instant, was not hop beer at all, but "small beer." It was a regular "brew," and, the fermentation being perfected, an alcoholic beverage, and its strength in that dangerous and pernicious poison would just be in proportion to the saccharine used and decomposed in the shape of malt sugar, or sugar proper. Now, hop beer, as generally understood, is very different from this; it is innocent, mild, refreshing, somewhat invigorating (not stimulating), a little nourishing in proportion to the sugar preserved, and the hop bitter also a little tonic; in fact, it resembles the simple beverage, of which we have record in history. We know that hops were introduced into England in the reign of Henry VIII. There is an old rhyme which runs thus—

"Hops, reformation, and beer
Came into England all in a year."

We read that this hop beer was brewed and drank so fresh that it was delivered at the houses as fetched from the brewery fresh every day, and well would it have been for the race had they kept to this simple beverage. We see, then, that it should be fresh, and, therefore, free from alcohol. It should only "work" just sufficient to generate a little carbonic acid gas, and not to destroy the entire sweetness. You have given in your various receipts the principle to work upon. Quantities cannot well be given, as tastes differ so much; some like it sweeter than others; others more hop bitter. I think sugar preferable to malt, as being more simple and quickly prepared, and does not require so much "fining." Therefore, take liquorice water to taste, and to taste decoction or extract of hops, which can be prepared and kept on hand to save time. Heat to nearly milk warm, then add a little yeast; let "work" quietly in a mild temperature for about 48 hours, then fine with isinglass or prepared gelatine, and if colour is desired add a little burnt sugar. It then should be bottled and tied down, and it is almost fit for immediate use. Keep in a cool place. It can be flavoured to taste with ginger, lemon, &c. It should not be kept in cask on draught, as contact with air would generate further fermentation, and spoil it. It would also be in danger of running into alcoholic fermentation, then very soon into the acetous. This should be particularly avoided. There is an "unfermented Burton ale" extensively used in England, which gained the £1,000 prize of the "Church of England Temperance Society." In conclusion, it is gratifying to know that the tendency of the age is to go back as near as possible to Nature's only menstruum and solvent, pure water, or flavoured only with Nature's beautiful and varied syrups of fruit, which for ages have been destroyed by fermentation, the product of which, alcohol, has been or is playing and havoc in the world.

King River, Oxley, February 10.

—*Australasian*.]

THE BOTANIC GARDEN.

There are several flowers in bloom near the entrance to the Garden which deserve a passing notice. One of these is the graceful *Sterebergia*, a specimen of which may be seen at the left-hand corner of the main walk facing the Director's residence. It will be readily recognised by its resemblance to the flower of the potato-plant, of which indeed it is a near relation. Both belong to the Nightshade family (*Solanaceae*), of which a still prettier member is the *Solanum jacobinoides* whose five-cleft corolla of delicate lilac and ornamental fluted column of yellow-coloured stamens surrounding the elegant style, may be seen entwined round a China rose-bush at the corner of a bed not far from the conservatory and facing the splendid *Demerara* pine. The nightshade family—of which there are about seventy genera and over a thousand species, mostly inhabiting the tropics—is noteworthy for the fact that about one-half of its members are poisonous, and the remainder either innocuous or even nutritious. The family has been separated into two divisions mainly on that account. To the one division belongs the potato, and to the other the tobacco plant and the deadly nightshade. The flowers in this order are mostly isomorous, i.e., they have the same number of sepals and petals, and in nearly every case of stamens as well. Besides the potato this order furnishes our native races with the gungyang, or Australian potato, obtained from *S. vavum*; Tasmania with the kangaroo apple, the fruit of the *S. lacinatum*; the East Indies with chillies, the Mexican name for the fruit of the capsicum; Canada and this colony with the tomato; the Cape of Good Hope with a gooseberry, and Peru with a winter cherry. The light-purple tubular flowers of the *jochima* shrub, near the the baubinia tree, opposite the workmen's yard, also belong to a member of this interesting family. Near the the entrance of the Garden, and indeed, scattered throughout the grounds and to be met with all over Adelaide, is the pretty little five lobed corolla of the vines, or periwinkle, as it is called at home. Though so common a flower it is none the less deserving of observation. It belongs to the same family as the oleander, of which this colony seems to possess a greater number than even Italy itself. Like the nightshade family, the bogbane family (*Apocynaceae*) is extremely poisonous. Notwithstanding its beauty, the common oleander is one of the worst of the lot, and many children in Adelaide have probably owed their death to their fondness for its flowers. A peculiarity about them is the long feathery appendages by which the anthers are terminated, and it is worth while pulling the flower to pieces for the sake of observing the strongly fortified position of the fine stamens entrenched round the pistil as if determined to protect it. The famous Tanghin poison, formerly used in Madagascar as a criminal ordeal, was furnished by the seeds of a member of this order (*Corbera Tanghin*), and an East Indian species of the same genus—with long yellow, sweet-scented corolla and unmistakable oleander-like leaves—adorns the lawn opposite the workmen's yard. A striking peculiarity about this flower is the apparent absence of any reproductive organs, the long tubular corolla being seemingly quite empty. On stripping the corolla, however, and pulling back the remnants of the petals at the base of the tube, the whole arrangement will suddenly spring into view like a Jack-in-a-box. This order also furnishes South Africa with the famous Komboe arrow poison, while a species at the Cape is used as a poison for fish. Bogbane shrubs are generally noted for their acrid milk-juice, but in one case—that of the cowtree of *Demerara*—the juice makes a tolerably good substitute for the real thing.—*Australasian*.

WHAT IS THIS DISEASE THAT IS COMING UPON US?

Like a thief at night it steals in upon us unawares. Many persons have pains about the chest and sides, and sometimes in the back. They feel dull and sleepy; the mouth has a bad taste, especially in the morning. A sort of sticky slime collects about the teeth. The appetite is poor. There is a feeling like a heavy load on the stomach; sometimes a faint all-gone sensation at the pit of the stomach which food does not satisfy. The eyes are sunken, the hands and feet become cold and feel clammy. After a while a cough sets in at first dry, but after a few months it is attended with a greenish coloured expectoration. The afflicted one feels tired all the while, and sleep does not seem to afford any rest. After a time he becomes nervous, irritable, and gloomy, and has evil forebodings. There is a giddiness, a sort of whirling sensation in the head when rising up suddenly. The bowels become costive; the skin is dry and hot at times; the blood becomes thick and stagnant: the whites of the eyes become tinged with yellow, the urine is scanty and high-coloured, depositing a sediment after standing. There is frequently a spitting up of the food, sometimes with a sour taste, and sometimes with a sweetish taste; this is frequently attended with palpitation of the heart; the vision becomes impaired with spots before the eyes; there is a feeling of great prostration and weakness. All of these symptoms are in turn present. It is thought that nearly one-third of our population has this disease in some of its varied forms. It has been found that medical men have mistaken the nature of this disease. Some have treated it for a liver complaint, others for kidney disease, etc., etc., but none of the various kinds of treatment have been attended with success, because the remedy should be such as to act harmoniously upon each one of the organs, and upon the stomach as well: for in Dyspepsia (for this is really what the disease is) all these organs partake of this disease, and require a remedy that will act upon all at the same time. Seigel's Curative Syrup acts like a charm in this class of complaints, giving almost immediate relief. The following letters from chemists of standing in the community where they live show in what estimation the article is held:—

John Archer, Warthill, near Sheffield:—I can confidently recommend it to all who may be suffering from liver or stomach complaints, having the testimony of my customers, who have derived great benefit from the Syrup and Pills. The sale is increasing wonderfully.

Geo. A. Webb, 141, York-street, Belfast:—I have sold a large quantity, and the parties have testified to its being what you represent it.

J. S. Metcalfe, 55, Highgate, Kendal:—I have always great pleasure in recommending the Curative Syrup, for I have never known a case in which it has not relieved or cured, and I have sold many grosser.

Robt. G. Gould, 17, High-street, Andover:—I have always taken a great interest in your medicines, and I have recommended them, as I have found numerous cases of cure from their use.

Thomas Chapman, West Auckland:—I find that the trade steadily increases. I sell more of your medicines than any other kind.

N. Darroll, Clun, Salop:—All who buy it are pleased, and recommend it.

Jos. Balkwill, A.P.S., Kingabridge:—The public seem to appreciate their great value.

A. Armistead, Market-street, Dalton-in-Furness:—It is needless for me to say that your valuable medicines have great sale in this district—greater than any other I know of, giving great satisfaction.

Robt. Laine, Melksham:—I can well recommend the Curative Syrup from having proved its efficacy for indigestion myself.

Frickheim, Arbroath, Forfarshire, Sept. 23, 1882.

Dear Sir,—Last year I sent you a letter recommending Mother Seigel's Syrup. I have very much pleasure in still bearing testimony to the very satisfactory results of the famed Syrup and Pills. Most patent medicines die out with me, but Mother Seigel has had a steady sale ever since I commenced, and is still in as great demand as when I first began to sell the medicine. The cures which have come under my notice are chiefly those of liver complaint and general debility.

A certain minister in my neighbourhood says it is the only thing which has benefited him, and restored him to his normal condition of health after being unable to preach for a considerable length of time. I could mention also a great many other cases, but space would not allow. A near friend of mine, who is very much addicted to costiveness or constipation, finds that Mother Seigel's Pills are the only pills which suit his complaint. All other pills cause a reaction which is very annoying. Mother Seigel's Pills do not leave a bad after-effect. I have much pleasure in commending again to suffering humanity Mother Seigel's medicines, which are no sham. If this letter is of any service, you can publish it.

Yours very truly,
(Signed) WILLIAM S. GLASS, Chemist.

A. J. WHITE, Esq.

15th August, 1883.

Dear Sir,—I write to tell you that Mr. Henry Hillier, of Yatesbury, Wilts, informs me that he suffered from a severe form of indigestion for upwards of four years, and took no end of doctor's medicine without the slightest benefit, and declares Mother Seigel's Syrup which he got from me has saved his life.

Yours truly,
(Signed) N. WEBB,
Chemist, Calne.

Crop and Weather Report.

[FOR THE WEEK ENDING THE 15TH APRIL 1885.]

General Remarks.—Slight showers have fallen throughout the Madras Presidency, Mysore, in several districts in Bombay, and the Central Provinces. In the North-Western Provinces and Oudh and the Punjab rain has fallen in a few districts. Light rain is also reported from some of the Central India and Rajpootana States. In Bengal there has been rain in some districts, and in Assam the fall continues to be generally heavy.

In Madras the standing crops are generally in fair condition, but in Mysore prospects are reported to be still uncertain. In Coorg rain is much wanted for the coffee blossoms.

The *rabi* harvest has been nearly completed in most districts in the Bombay presidency, and preparations for the *kharif* have commenced in places. Scarcity of drinking-water continues to exist in parts of Dharwar and Belgaum, and of fodder in parts of Dharwar.

In Central India and Rajpootana harvesting is going on, and prospects are generally good. The *rabi* harvest has commenced in the Punjab and promises well. In the North-Western Provinces and Oudh and the Central Provinces harvesting, threshing, and winnowing are in progress. In the former an average outturn is expected.

In Bengal the *rabi* harvest, which has been nearly completed, has yielded a good outturn on the whole. Ploughing is in progress and sowing of early paddy and jute has commenced in some places. Ploughing and sowing continue in Assam, and prospects are generally favourable.

Cholera and small-pox are reported from parts of Madras, Bombay, Bengal, the North-Western Provinces and Oudh, and British Burmah, otherwise the public health is generally good.

Prices are fluctuating in Bengal and the Punjab : elsewhere they are generally stationary.

Madras.—General prospects fair, except in parts of Bellary and Anantapur.

Bombay.—Slight rain in parts of eleven districts. *Rabi* harvest completed or nearly so in most districts ; *kharif* preparations commenced in parts of Sholapore and Dharwar ; wheat and peas slightly injured by rust in parts of Shikarpore, and cotton and *juari* by rain in one taluka of Belgaum. Scarcity of drinking water in seven talukas of Dharwar, and three of and Belgaum, of fodder in three talukas of Dharwar. Fever and cattle-disease in parts of nine and cholera and small-pox in parts of eleven districts.

Bengal.—Slight rain fell in some districts, but more rain is much wanted generally. Ploughing is going on, but is retarded in certain districts for want of rain ; harvesting of *rabi* crops is nearly finished with a good outturn on the whole ; early paddy and jute are being sown in a few districts ; harvesting of *boro* paddy has commenced in two districts. A storm which occurred on the 29th ultimo in the district of Tipperah greatly damaged property and caused some loss of life. Prices of food-grains show a slight advance in a few districts, otherwise they are stationary. Sporadic cases of cholera and small-pox are reported.

N.W. Provinces and Oudh.—Slight showers have fallen in some districts. Harvesting operations approaching completion ; an average outturn expected. Markets are well supplied and prices steady. Public health fair ; some cases of cholera reported from Benares, Agra, Jhansi, and Aligarh.

Punjab.—Rain in the Sialkot, Rawul Pindies, Shahpore, Dehra Ismail Khan and Peshawur districts. Health good. Crops in the Peshawur district damaged by excessive rain and hail storm, elsewhere prospects are on the whole good. Prices fluctuating.

Central Provinces.—The weather has been very variable with frequent thunderstorms and much cloud at times. *Rabi* harvesting continues in the northern districts, where the outturn of wheat is proving less than was anticipated owing to the mildew which resulted from the rain of January and February last.

British Burmah.—Cholera prevalent in parts of Amherst and Shwegyin districts ; small-pox prevalent in parts of Tharawaddy, Hmawda and Thapetmaysa districts, otherwise public health good ; cattle-disease in Thapetmaysa district. Weather sultry ; symptoms of south-west monsoon.

Assam.—Weather rainy and cool. Sowing of *aus* crop almost over ; ploughing for *dumahi* and *murali* crops continues ; *Ahu dhan* being sown, prospects good. Public health fair.

Mysore and Coorg.—Paddy crop is ripening ; coffee blossom out, but more rain wanted. Prices stationary. Prospects of season and public health good.

Benar and Hyderabad.—Weather hot and cloudy. Threshing of *rabi* continues in places ; *kharif* preparations in hand, reaping of *tabi* has commenced. No sickness among men and beasts.

Central India States.—Weather cloudy. Health good. Harvesting continues.

Rajpootana.—Health good. *Rabi* harvest operations in progress. Weather cloudy. Prices show tendency to fall.

Nepal.—Weather hot and dry. The spring crops are poor from want of rain.

Editorial Notes.

THERE was a time, and not long ago, when the Indian cotton trade with Eastern Africa, and especially Mozambique, was in a most prosperous condition. Mr. Holmwood, while recently addressing the Society of Arts in London, pointed out that a remarkable demand had at one time risen in Mozambique in favour of Indian cottons. The reason why they found favour with the natives was, that they combined durability with cheapness, and the way in which the trade rapidly developed, it seemed as if cottons from India were destined at no distant date to monopolise the market. But a difficulty then arose in the way of the Indian exporter in the Mozambique tariff, which levied duty on cotton cloths by weight, thus treating coarse cheap Indian fabrics very unfairly in comparison with the finer kinds. Notwithstanding this heavy handicap, the trade still continued to flourish, until 1882, when a special tax was placed upon Indian cotton. The object of this could have been nothing less than the shutting out of the article altogether from the marts of Eastern Africa, and a heavy blow dealt to the trade. But before the worst could be accomplished, the English Foreign Office stepped in, and its interference put a stop to such high-handed proceedings. It is true the obnoxious tax was repealed, but rather late, as the mischief had been done, and several firms which had opened branch firms at Mozambique, had already closed them, before the results of the interference of the Foreign Office were known. Now, however, no reasons exist why the Indian cotton trade should not be restored to its original status, and regain the position which it held before the imposition of this special tax. The Foreign Office having once interfered successfully, it might go a step further and demand a fair treatment for it. There is great injustice in taxing cheap and coarse cotton at the same rate as finer cloths, and as the Portuguese officials cannot or will not understand this, some pressure should be brought to bear upon them to perceive the inequitableness of such proceedings.

* * *

THE cultivation of cacao in Ceylon has not, we find, been attended with any marked degree of success. The plant is subject to the ravages of a deadly enemy in the earlier stages of its growth—we refer to the insect (a bug) known to entomologists by the name of *Helopeltis antonii*. This little pest is provided with a formidable proboscis in the shape of a pumping machine, by which it sucks out the juice of the tree. Any tree on which it fastens is sure to perish. These pests hunt in packs.

MR. MARTIN has contributed a paper on the cacao, in which he suggests various methods of destroying this insect, notably that adopted by Dr. Friemen and others, *viz.*, that of destroying the insect by collecting it in its various stages. The suggestion about burning affected branches and pods is a good one, but liable, in some measure, to cause injury to the trees. Burning should only be resorted to in extreme cases.

**

It is matter for regret that this valuable plant should be subject to a scourge like the *Helopeltis*, but according to Mr. Martin, the cultivation of cacao in Ceylon may yet be attended with success. Those who have invested capital on it, must naturally be somewhat disappointed; and we can only hope that means will be discovered of ridding the cacao of its enemy.

**

THE cultivation and export of tea from Ceylon seems to be making headway, and there is every reason to anticipate that it will take a prominent place in the tea market. The falling off, which has lately been observable in the cultivation of coffee in Ceylon, has given place to an extraordinary impetus to tea plantation.

**

Thus we find that the exports of tea during the past year exceeded a million pounds. The exact figures quoted up to the 26th March last, were 1,010,255 lbs. against 612,388 lbs. to the same period last year. These figures, it will be observed, show a marked rise.

**

LAST year there were shipped altogether 2,262,000 lbs., and the quantity estimated to be shipped this year is 3,500,000 lbs. This speaks much for the enterprise of Ceylon Tea Planters. The quality of the tea is, we are glad to observe, all that can be desired.

**

A VERY interesting report has just been submitted to the Chief Commissioner of British Burmah, by Mr. R. Romanis, Chemical Examiner to the local Government, on the oil well and coal in the Thayetmyo district. The oil-wells are at Padaukpin, about eight miles from Thayetmyo on the Mindon road. Of seven wells there are only three kept in repair, and of these only one was yielding oil at the time of his visit. The oil flows very slowly; the produce is only one barrel monthly. It occurs in fissures in a hard blue shale (dipping 35 deg. W.), which contains fossil marine shells, which are generally much decomposed by the action of water; often there is only the cast of the shell in the clay remaining. At Yenanchaung in Upper Burma the oil-bearing stratum is a similar blue shale with bands of sand, into which the oil diffuses from the shale and through which it percolates in the wells. The shale at Padaukpin seems almost impervious. He observed a place where the shale cropped up to the surface. It was converted superficially into clay by the action of water. The oil was found lining small cracks and cavities. When a piece of the shale was powdered and diffused through water, the oil came to the surface in a thin film. A specimen of the shale was analysed and found to contain 0.16 per cent of oil. The rocks overlying the oil-bearing stratum appear much harder than those at Yenanchaung. It appears to be a different geological formation, deposited under different conditions. A boring was put down to a great depth some years ago in one of the ravines to the northward. It ended in hard rock, without finding oil. He did not know why the place in question was selected; the whole district was very unpromising.

**

THE coal is found in a ravine of the south-western spur of the second, or middle hill of the group of lime-hills south of Thayetmyo. When he visited the place, an escarpment had been made along the east side of the gorge; at the north end a drift had been driven into the hillside through a hard blue shale to a depth of about 20 feet; at the end of the drift there was a thin seam of coal and carbonaceous shale dipping at an angle of about 30°. Below this another drift had been made, but had fallen in. The seam of coal is said to be four feet thick. Further south, again, a pit had been sunk to a depth

of 30 feet, following the course of two small seams of coal here dipping at an angle of 75 to 80 deg. They are four feet apart at the top, but gradually approach and will unite probably three or four feet lower. Five or six yards further south there were seen two more vertical beds of carbonaceous shale. One of these is said to be the seam worked about 30 years ago. The traces of the old workings are now concealed under the rubbish thrown down from the escarpment above. The old drift is said to be vertically below the limekiln on the hillside. The blue shale below the coal is full of vegetable remains, apparently grasses or reeds. Above the coal the shales appear to be unfossiliferous. Over the shales are sandstones. Above these again, there is a greyish pink limestone; then over all, forming the crest of the hill, is a white limestone composed of fossils, nummulites, and marine mollusca. It seemed to him that the coal deposits of the Arakan Yoma have been formed in the swamps and lagoons of a river delta. Similar deposits of very recent date were found in the neighbourhood of Rangoon. Thus at Insein a boring showed a thin bed of lignite. Beneath the alluvial soil, on which part of the town of Rangoon stands, there is a stratum of decomposed vegetable matter about two feet thick, thinning out and disappearing where it meets the sandstones, on which the cantonment stands. Above this stratum there is a fine blue clay; above the clay is the sandy clay of the rice-fields. The same order exists at each of the coal outcrops in Burmah,—argillaceous sandstones, blue shale, coal. At Thayetmyo the deposits have evidently been formed while the land was slowly sinking beneath the sea, the limestones overlying the shales and sandstones having been deposited on a sea bottom, when the head of the Gulf of Martaban was at Yenanchaung or Sagaing. The sudden change in the angle of dip shows that there has been a great disturbance of the strata. It seemed to him that the coal worked 30 years ago was a portion of the present four-foot seam, and that a fault runs between the main hill and the southern spurs; but Mr. Lewis, who is carrying on the work, seems to think that the old drift was driven in the wrong direction, and that he will find the seam at the bottom of the pit he is sinking. On this theory there should be two seams four feet thick, separated by 60 or 70 feet of shale. It is noteworthy that a similar nummulitic coal-field by the banks of the Indus has just been carefully tested by boring, and found to be so irregular as to be worthless.

**

THE following is a summary of Messrs. William, James and Henry Thompson's fortnightly Circular on Indian Tea. Since the 12th instant 40,000 packages have been catalogued for sale, including 700 of Ceylon and 2,000 of reprinted tea. The subsidence of the excitement in the country, and the extra supplies brought to market in consequence of the improvement in prices have checked the activity of buyers, and the sales have passed quietly, but without any flatness of tone. Demand has continued strong for all the better qualities, especially for fine Pekoes and Broken Pekoes, at firm to rather dearer prices; but for inferior grades between 8d. and 1s. 2d., upon which the improvement was most marked, prices have receded, and fully ½d. of the recovery has been lost. During the first 20 days of this month duty was paid in London upon 17,500,000 lbs. as compared with 8,500,000 lb. in 1884, and some of the dealers think the increased rate will be maintained up to the date of the Budget. This of course entails a financial strain of which the effect will be felt for many weeks to come, and which must contract the volume of business until the surplus duty-paid stocks are worked off.

**

WE hear from Australia that the wine industry is now passing through a critical stage of its existence. A pastoral paper writing on the subject remarks that its progress has varied considerably during the past ten years, but at no time has there been such a visible depression as there exists in it at the present. In the Upper Murray, which is one of the principal sources from which the supplies are drawn, and where the tone of the market of the world is always indicated by the financial condition of the producers, the industry is apparently in a depressed state, but whether it is on account of the immensely increased quantity of the produce, or whether it is an

extraordinary diminution of the demand, the experience of the next few years only will demonstrate. Ten years ago the present stagnation was approached, and at that time a mild description of panic set in which resulted in the rooting-out of some vineyards, the neglect of others, which necessitated years of labour to recover them from the damage sustained, and a decided indication on the part of buyers and speculators in the matured article, or the immatured must, to hold temporarily aloof from further operations. In the course of the next two years, however, there was an evident revival. Those who had neglected their vineyards went vigorously to work to revive them, and those who had rooted their vines out when under the impression that the industry had collapsed set to work, and planted out larger areas than they had ever wrought previously. Hundreds, and probably thousands, of acres were trenched and vines planted out; the demand increased to a remarkable extent; and although the prices never recovered their former level, the supply for a time did not satisfy the demand; but latterly this activity has given strong indications of having arrived at its maximum height. In Albury, for instance, where the trade naturally gravitates on the New South Wales side of the Murray Valley, most of the cellars are heavily stocked; and in one of them there is no less than 350,000gal. of wine at the present time. The same firm has a stock approaching 100,000gal. stored at their export branch in Sydney; and they anticipate obtaining a return of from 80,000 to 100,000 from the vintage which is just about commencing. With such a stock in hand it cannot be expected that they will be prepared to operate to any great extent during the present season; and as they were the principal buyers in past years, the fact of their ceasing to operate will have a depressing if not a disastrous effect upon the prospects of the smaller growers, who looked up to them as a source for the absorption of their produce. The same, in a minor respect, may be said of all the other buyers on both sides of the river within 40 miles below Albury. Many of the buyers in and about Rutherglen, Brown's Plains, and Barnawatha, who, at one time, were in the habit of purchasing grapes from the New South Wales side of the river, and converting them into wine on the other, are not disposed this year to speculate; and this fact, together with those previously stated, has placed the small producer in a rather awkward predicament. Many of them are unable to make the necessary preparations for the disposal of their produce owing to the near approach of the vintage; others have no casks, and are unable to obtain them in sufficient quantities to store the quantities anticipated; and others look upon the present evidences of depression as a clear loss of the present year's yield. To the small vigneron the deprivation of the usual outlet for either his grapes or must means a considerable loss, even if he had the storage capacity in the shape of casks, because few of them have the necessary experience to mature their wines sufficiently well to enable them to successfully enter into competition with the expert hands engaged by the large buyers; and even if they could do so their only market falling Albury is cut off from them by the prohibitive duty of 6s. per gallon imposed on wine made in New South Wales and exported to Victoria. Taking all the circumstances into consideration, the outlook for the wine industry this year is not a satisfactory one for the producers, and it may be safely asserted that the returns in the shape of cash this year will fall very considerably short of what was anticipated.

.

A CORRESPONDENCE just published by the Government of Madras on the subject of the manufacture of muslins throughout the country has brought to light the fact that only in three places in all India is the industry carried on to any extent. These are Arani in the Chingleput District, Chicacole in Ganjam, and Dacca in the Bengal Presidency. From elsewhere the replies received by the Madras Government have been that muslins are not manufactured at all. Here and there muslins of small size, low price and evidently of inferior quality, are said to be turned out. The Deputy Commissioner of Bandora states that "the art of spinning fine thread, such as that noticed in Chanda before the settlement in 1863, has died out, and the finest yarns now used are all machine-made, and some

of them are muslin numbers. The opening of the railways and the introduction of Europe goods with the coincidence of the 1868-69 famine and a brisk demand for cotton from the Berars draw away most of the thread-spinners to the Berars." Mr. Prier, the Collector of Chingleput, is of opinion that the English yarns have spoiled the native cotton spinner's trade, that spinning the exquisitely fine thread, used for native muslins, has thus died out, and that this has led to the reply that no muslins are manufactured in any other parts of India. From the detailed statement appended to the Collector's letter, it appears that the cost of Arani muslin varies from Rs. 50 to Rs. 200 per piece of 48' x 4'6", while the cost of that woven at Dacca runs from Rs. 150 to Rs. 275 per piece of 60' x 3'. Considering the extraordinary fineness of the best description of Dacca muslin, the Madras Board of Revenue do not consider the price exorbitant, though it is very possible that the cost price of the second class and coarser muslins of Dacca may have been exaggerated owing to over-estimation of the time required to weave them. The production of ten yards of the fairy-like texture which will pass through a ring represents a year's labour of two weavers, but the same cannot be said of the coarser qualities. It is said to reflect on the decline of a trade which has flourished for centuries, for the products of the Dacca loom were appreciated by the Greek and Roman ladies hundreds of years before the Christian era.

.

A CORRESPONDENT says:—The attention of paper-makers is directed to a new raw material, which is derived from the trunk and branches of the yucca, the leaves of which yield fibres suitable for ropes, strong sacking, brushes, &c. The yucca, which in northern climates is merely a shrub, grows in Honduras to a height of upwards of forty feet, the trunk being about thirty-six inches in circumference, and with the exception of the outer bark, the whole of the tree is composed of fibre suitable for paper manufacture. It is found most abundantly on the Atlantic coast of Honduras, where the yucca attains its largest growth, and owing to the local rivers being navigable and flowing into the Atlantic Ocean, every facility is afforded for its continuous and economical shipment to the ports of the United Kingdom. The yucca trees in these valleys will yield several cwt. of fibre to each tree, of a quality which will produce over ninety per cent of its dry weight as paper stock of excellent quality. It is easily reduced, a short alkaline boiling prepares it for the beating engine, and being readily bleached, the cost for chemicals is reduced to a minimum. The papers produced are strong and of fine texture, equal in quality to any description made from linen rags, and possessing the natural advantage of taking black or coloured inks both rapidly and clearly, thereby rendering such papers especially suitable for use in the fastest newspaper machines, as well as for the production of impressions from engravings, whether upon steel, copper, or wood, the results being equal to those obtained with India paper.

.

THE total imports of rag and paper-stock at the port of New York during the month ended January 31, as reported, were 40,510 bales, an increase over the corresponding month of last year of 12,313 bales; and an increase, compared with January, 1883, of 26,981 bales. There was an increase from last year in rags of 10,768 bales. Manila stocks show a decrease of 412 bales, and old papers a decrease of 13,666 bales. Wood pulp itself shows an increase of 3,323 packages. The total figures in each class of stock, during the month of January for the years 1885, 1884, and 1883, are as follow:—

	1885.	1884.	1883.
Rags	24,981	14,213	9,503
Old papers	1,440	2,806	1,772
Manilla stocks	4,954	5,366	2,284
Wood pulp	9,135	5,812	...
Total	40,510	28,197	13,559

The arrivals from the different ports were as follow: Amsterdam, 209 bales rags; Antwerp, 1,806 bales rags; Aspinwall, 217 bales rags; Bremen, 991 bales rags, 100 bales manillas; Bristol, 188 bales manillas; Calcutta, 989 bales rags; Cadiz, 491 bales rags; Copenhagen, 893 bales rags, 6,800 bales wood

pulp, 36 bales manillas; Dundee, 317 bales rags, 89 bales old papers, 1,316 bales manillas; Genoa, 97 bales manillas; Glasgow, 136 bales rags, 76 bales old papers; Hamburg, 3,767 bales rags, 103 bales old papers, 325 bales manillas; Havana, 95 bales rags; Hull, 7,268 bales rags, 35 bales old papers, 785 bales wood pulp, 203 bales manillas; Liverpool, 581 bales rags, 39 bales old papers, 1,369 bales manillas; and London, 46,946 bales rags, 813 bales old paper, 1,046 bales manillas; Newcastle, 86 bales rags, 1,600 bales wood pulp; Rotterdam, 843 bales rags, 285 bales old paper, 283 bales manillas; Pillan, 1,545 bales rags, and St. Jago, 58 bales rags.

.

In expressing surprise that the Bombay mill-owners do not seem to be aware of the fact of Persia's demand for cotton manufactured goods being supplied by England, and not India, an Ispahan correspondent writes:—"The connection by trade between Persia and India dates from very ancient times, when each supplied its own want with the products of its hand looms and those of its agricultural industries, and exchanged their surpluses with one another. Armenian merchants from Julfa (in Ispahan) were, it is believed, among the first foreigners who explored the channels of trade in Hindustan, and their commercial enterprise repaid them with boundless wealth. This enabled them to construct in their palmy days the Armenian quarters in the town of Julfa, numerous convents and churches, and mansions that still retain traces of their pristine glory. Later on, the advent of Europeans, principally English, and the development of the East India Company in India, combined with the introduction in England of machinery for weaving purposes and the lavish extravagance of the Julfa Armenian merchants, gradually degraded the latter into a state of comparative indigence, and the bulk of the Persian and Armenian weavers were reduced to penury by being thrown out of their customary occupation. Persia, then, by heavy exports of her gold and silver in return for consumable commodities, became impoverished, but owing to the revival of some of her ancient industries, Southern Persia, at any rate, has fairly begun to recover herself, and the value of landed property in general both in Ispahan and Fars has been quadrupled.

.

The Manager of the Devala Gold Mining Co., writing under date the 9th February, says:—"We have cleaned up after crushing 70 tons from the 300 ft. level. This, as I told you in a previous report, was not a prospect, but a lot of quartz and mullock lying at the mouth of the tunnel, which I did not at first consider payable stuff. After testing it, however, I saw it was not so poor as I had thought, and as it lay in our way I put it through the mill, and the 70 tons yielded 12 ozs. or very nearly 3 dwts. 9 grs. per ton. The lot I am putting through now is from the 140 ft. level, and from the appearance of the plates it should give a better result than we have ever had before. The old tunnel has been driven 7 ft. 140 ft. level, 8 ft.; 200 ft. level, 4 ft.; 200 ft. cross-drive 8 ft.; 300 ft. level, 6 ft.; 300 ft. cross-drive 14 ft.; 400 ft. level 100 ft. The 200 and 300 ft. cross drives have broken through into levels above them. The drives were necessary to secure ventilation, and they were useful also as prospecting drives. At Harewood Reef there is no change to report. The cross cut has been driven 4 ft. more. February 16.—Yesterday we cleaned up 75 tons from the 140ft. level. The quartz was taken from a rise we are putting up to connect this level with the 200ft. level about it, and it has yielded a trifle over 18 oz., or nearly 5 dwts. per ton. The old tunnel has been driven 10ft. 140ft. level 7ft.; rise up from same, 3ft.; 200ft. level 5½ft.; 300ft. level, 6ft.; 400ft. level, 13ft. We are putting in another level to cut the reef 100ft. further along the line. At Harewood Reef the cross-drive has been driven 5ft. this week; the stone is improving in appearance, and now contains small prospects of gold. The ground is still very hard."

.

No observant person in Bangalore, accustomed to take his or her "walks abroad," can have failed to have become deeply impressed with the stern fact that we are on the eve of a water famine, with all its attendant horrors. The scarcity of water appears to be more felt in the native town than in the station, for in the former place, not only is water for washing, cultivation, and such purposes, quite unavailable, but drinking water is becoming more and more scarce every day, and people are driven to all sorts of expedients to procure a supply. All the tanks and *goontahs* are dry. There are just a few hundred gallons remaining in a corner of the Dhurmosdy

tank, which used to supply all the western half of the Pettah, and even that quantity must be exhausted in a day or two. The bed of the Sumpungee tank has, of course, been dry for the past four years, owing to its supply channels being directed to fill "Sankey's Folly" at Hebbal, but there has always been a sufficient supply in the *goontah* excavated in its bed at the western end during the famine. Passing the tank yesterday, we noticed that the *goontah* was as dry as an oven, and two or three attempts to sink wells in the *goontah* again, and thus obtain a small supply of water, proved abortive. The market gardens on the Pettah eastern suburbs are suffering greatly for want of water, and all over the place we saw people employed in sinking wells in the hope of getting water,—a hope which, in most cases, was not realised. The same attempts might be seen in other places,—anywhere where there seems just the ghost of a chance of getting a little water. If the windows of heaven are not thrown open within the next fortnight or so, we fear that a water-famine will inevitably ensue.

.

The sericulture experiments, says a contemporary, which were commenced last year on a small scale in the Changa Manga Reserve, near Lahore, and proved so successful, are now to be tried on a much larger scale. The Forest Department have obtained a supply of imported Japan seed through Messrs. Lister and Co. of Bradford; and a supply of home-reared seed from the Manager of Messrs. Lister and Co.'s firm at Dehra Doon. The advantages of rearing silkworms at Changa Manga are, that the new leaf is procurable early in the season, owing to forced irrigation; the large supply of food for the worms; the absence of hot winds in the forest; and the fairly even temperature of Changa Manga. Two large sheds, 1,618 ft. in length and 20 ft. wide, have been put up. In these are two rows of shelves, 5 ft. wide, with two tiers in each; so that when they are all occupied, there will be 32,360 square feet of worms devouring greedily all that is put near them. The worms began to make their appearance towards the end of February, and in March last there were an immense number of worms—a sight well worth a run down from Lahore to see. The worms are now spinning, and there is a fine collection of cocoons. During the Christmas week, Mr. Lamarchand was deputed to Dehra Doon to inspect Messrs. Lister and Co.'s rearing operations in the Eastern Doon; and through the kind assistance of the gentleman in charge, he obtained a quantity of useful information, which will doubtless be applied to the proper purpose.

.

According to an English contemporary, the report of the medical officer of health for the port of London shows that during 1884 the imports of frozen meat amounted to the enormous quantity of 619,324 sheep and 115,377 quarters of beef. Most of these supplies arrived in "magnificent condition," but in some instances great deterioration had taken place during the voyage, involving heavy loss to the importers. One ship, which arrived in August, had 2,279 quarters of beef destroyed out of a total freight of 2,289 quarters; but this proportion seems to have been altogether exceptional. When meat is ordered to be destroyed, it is sold for boiling down purposes, the process being carried out under official supervision, to prevent any finding its way into the market. The price obtained generally leaves a small balance for the consignees after all expenses are paid, but this goes only a very small way towards covering the loss. On the whole, however, this important trade has now reached a reasonably safe condition, thanks to the knowledge, gained through repeated failures, of the best way of maintaining the requisite degree of temperature in the storage chambers on board ship. It is noticeable that while the imports from Russia and the United States show a tendency to fall off, those from Australia, New Zealand, and the River Plate are increasing prodigiously. During the first quarters of last year, only 99,527 carcasses of sheep entered the port of London from these countries, but in the last quarter the number was 168,104.

.

A CIRCULAR has just been issued to the shareholders in the Colar Gold Mining Company, Limited, by the liquidators, which shows that, after all, the sale of the Company's property to the Indian Consolidated Gold Company is to be carried out, the limited opposition having been withdrawn. It is thought this result should be regarded with satisfaction by the shareholders in both the

Companies concerned, for it seems likely that the arrangement will be beneficial to both parties to it. The liquidators of the Colar Company will shortly send a cheque to their shareholders for their proportion or any cash balance that may be available for distribution.

.

We learn that Dr. Rowell, principal medical officer in the Straits Settlements, has set an example which might well be followed to a greater extent than it has hitherto been in this country, although we are well aware of the good work done in a similar direction by Dr. Day and Dr. Shortt. We refer to the formation of a scientific collection of the fishes and crustacea inhabiting both the seas and the rivers of the Malayan peninsula. Dr. Rowell, we find, obtained the assistance of a taxidermist trained at the Madras Museum under Dr. Biddie, and with his assistance he has got together specimens of something like 100 different species, in which the natural colours of the fish are most wonderfully preserved. It is intended to place the present collection in the Raffles Museum at Singapore, but Dr. Rowell proposes also to send home duplicates of as many of his collection as possible to the Indian and Colonial Exhibition next year, where they may be expected to prove objects of attraction.

.

A WRITER in an American contemporary says: "I discovered many years ago that wood could be made to last longer than iron in the ground, but thought the process so simple that it was not worth to make a stir about it. Posts of any wood can be prepared for less than two cents a piece. This is the recipe: Take boiled linseed oil and stir in pulverised coal to the consistency of paint. Put a coat of this over the timber, and there is not a man that will live to see it rot."

.

MR. J. C. DOUGLAS, of the Telegraph Department, author of a handbook of "Bee-keeping for India," writes to a contemporary: "I have to thank you for your article on my book. That Indian bees are very vicious if shot at, stoned, or irritated by much smoke is no doubt true, but with due care the large wild bees may be handled and kept under observation. Two German bee-keepers have handled them. A beginner in bee-keeping writes to me that he has just lost a stock he kept twelve days under observation, and I had a stock under observation which showed no signs of irritation, although I stood close to them, observed them minutely, and had large numbers of them flying round my head, and some striking against me. My first batch of Italian queens will be hatched in a day or two, and I should be glad to hear from any one willing to introduce Italians into his or her locality. This race is the one preferred in America; it yields most of the honey produced on the large bee-farms in Germany and America. All doubt as to Italian bees doing well in India is at an end. As a matter of fact they do very well indeed, but imported queens are very liable to be inferior, the journey being exceedingly injurious even to those which appear in good health on arrival. Of thirteen queens imported, seven were imported in full stocks, two in small stocks, and four in cages; only two survived and one of these has suffered in fecundity from the journey. Mr. Benton, a German dealer, offers to send stocks of bees to Bombay or Colombo for £5 a stock; the land journey has then to be performed, and the queens would not be improved by the journey, hence £5 a stock would be a low price for a good stock with a country-bred queen. I will send nuclei as far as practicable to persons willing to breed the bees; obviously breeding Italians would be better at present than simply keeping them for honey, although they are sure to get honey as soon as the bees are numerous. I will give the preference to naturalists and persons who have some practical knowledge of Indian or European bees. I charge nothing for the bees, but require the fullest instructions as to carriage, and that carriage and packing be paid. Bees cannot be sent in ordinary hives; they have to be packed in boxes costing Rs. 2 or 3 each, and the journey should be broken as often as practicable to let the bees fly. I have no doubt whatever that dealing in bees and honey will be found to pay in India, though at present I am most concerned to get the assistance of persons who would rather work to introduce bee-keeping than to make an

immediate profit. I have many correspondents, and I beg that any one requiring information will enclose a stamped and addressed envelope, and not ask me to make enquiries as to cost of carriage, etc., which I have not time to make."

.

THE Horse-Show at Rajkote held in December last, does not appear to have been a success; and the Bombay Government have marked their sense of dissatisfaction in a Resolution published on the 16th March last, which runs as follows:—

Resolution.—His Excellency the Governor in Council notices with regret that the horse-show held at Rajkote in December last was not very successful as regards either the number or the quality of the animals exhibited. The total number, including foals at foot, was 206 against 402 in the previous year, and 280 in 1882. There was a large decrease in the number of mares and indigenous colts and fillies shown. The inferiority of the animals exhibited, with the exception of a few belonging to the Chiefs, was sufficiently indicated by the fact that none were considered fit to be selected for remounts.

2. In the class for geldings there were only 9 animals exhibited as compared with 13 in the previous year. This is not satisfactory. Every endeavour should be made to remove the prejudice against castration which is said to prevail amongst the Kathiawari breeders. There were not so many entries in the new class for ponies as could be desired. This is attributed to the apathy of the owners themselves rather than to the scarcity of good ponies in the provinces. As the judges are unanimously of opinion that mule breeding in the province should be encouraged, his Excellency the Governor in Council has no objection to the proposed restoration of the class for mares used for mule-breeding, which was ordered to be abolished in paragraph 4 of Government Resolution No. 923, dated 30th January 1884.

3. The Gondal State obtained first prizes in five different classes. In other classes also the first prize was awarded to animals which were the property of Chiefs.

4. The Superintendent, Horse-Breeding Operations, should be requested to submit any suggestions which he may have to make regarding alterations in the prospectus of the show or other matters connected with it. The information called for in paragraph 2 of Government Resolution No. 4392, dated 29th May 1884, regarding the working of the new stud arrangements made by the Chiefs has not been furnished. The Political Agents should be requested to submit a separate report on the subject through the Superintendent, Horse-Breeding Operations.

.

As a rule official reports are anything but interesting documents. To the average reader the little nugget that lies at the bottom is hidden away from view by a debris of figures, and he hardly finds it a remunerative toil to remove the encumbrance. There are, however, exceptions to the rule, and we are glad to say that the report of Captain B. A. N. Parrott, Settlement Officer, Hanthawaddy and Pegu districts, is a lucid, instructive picture of the condition of the people over whom he rules. It is short and terse, and what is more to the purpose, there is scarcely a line in it which may be said to be superfluous. Captain Parrott says that the soil and character of the cultivation vary widely in different parts of this large tract, which contains sterile hills, rich forest, unculturable savannah and swamps, as well as rice-lands and garden-lands of varying richness, and considerable stretches of culturable waste. The Settlement Officer reports that in the middle of the tract the soils are "poor in appearance," having "been worked for many years." The population of the tract is 114,456 souls, or 104 to a square mile of gross area; it falls at 286 to the square mile of cultivation. The people are said to be less civilised than in the tracts further south and west; they are fairly well off, and have money to spare for pleasures and luxuries. The area of fallow is large, and cultivation throughout the tract is for the most part poor of its kind; but that is partly attributable to the small ratio borne by the population to the cultivated area. As the Settlement Officer points out (paragraph 124), the yield per acre usually varies inversely with the size of average holdings, that is to say, cultivators can till a small holding better than they can a large one. Out of a small number of cases (369 in all) in which inquiries were made, 46 per cent of the cultivators were found not to be in debt, 16 per cent had been in debt for more than a year, and 36 per cent had been in debt for one year. The average amount owed by each debtor of one year's standing

was Rs. 108, but the average amount owed by the older debtors was heavy, namely, Rs. 579 each. Much of the debt was attributed to loss of cattle. Boat-owners, handicraftsmen, bazaar-sellers, and other non-agriculturists are said to be well off. The selling price of paddy-land last year ranged from Rs. 3-8-0 to Rs. 10-8-0 per acre, but the Settlement Officer considers that land in Pegu can hardly be said to have as yet a market value. The average area of a cultivator's holding ranges in the several tracts from 13 to 50 acres.

The number of tenants holding rice-land under landholders is 2,989, and they till 53,802 acres, or 21 per cent of the total cultivated area. Nearly one-half of these sub-tenants were found to be "paying revenue only," that is, the landholders allowed them to cultivate without claiming any rent. In the majority of cases where rent was demanded the Burman custom prevailed, whereby the sub-tenant pays the revenue and cesses, and pays also as rent to the landholder 10 per cent on the gross outturn of the sub-tenancy. The average payment made by sub-tenants of this class came to Rs. 3½ per acre of rice land as compared with the existing revenue rate of Rs. 1½ per acre. The rent paid by tenants on waste-land grants under the old rules appears to range considerably below the customary rent paid by the sub-tenants of petty landholders. The Settlement Officer gives few particulars about the status and condition of sub-tenants. But in a district like Pegu, where holdings are large and sub-tenants occupy more than one-fifth of the cultivated land, the condition of this class will require watching. Separate reports have shown that, while there is plenty of land available in the neighbourhood, sub-tenants are fairly well off and can attain the status of independent cultivators after a few years' industry as field-labourers and sub-tenants.

DURING the past 14 years the cultivated area of the tract under settlement has increased from 101,979 acres to 256,059 acres, or by 151 per cent, while the land revenue has in the same period increased from Rs. 1,76,357 to Rs. 4,58,706, or 160 per cent. The present area of cultivation, as above stated, is the area ascertained by the cadastral survey, and is 19½ per cent above the cultivated area as stated by the thugyas before the regular survey. The last detailed revision of the assessment rates took place in 1861, about which time the prevailing price of paddy was from Rs. 30 to Rs. 50 per hundred baskets. In the year 1879 the revenue was increased summiarily by 25 per cent all round. In 1882-83 there was a sort of strike in some circles against payment of the revenue; but in 1884 the land revenue was collected punctually, and the number of processes issued was smaller than in any year since 1879.

THE Settlement Officer found five distinct classes of soils, some of which, however, were confined to small sections of the settlement field. He divided the whole area into eight assessment tracts according to the then relative facilities for the disposal of produce. All exportable paddy is carried by cart to the nearest navigable stream, and thence goes by boat to Rangoon. In future years a gradually increasing proportion of paddy from part of the assessment tract will go to Rangoon by the newly-opened Sittang Valley Railway. With an average rate of Rs. 70 per hundred baskets in Rangoon, the Settlement Officer estimates the local value of paddy to range from Rs. 30 per hundred baskets in the most remote tract to Rs. 65 in the tract nearest Rangoon. The present crop-cutting experiments on 165 plots in the different tracts showed the average yield to vary from 27 to 43 baskets of paddy per acre, and the total average to be 36 1/6 baskets per acre. Old records show that the test crop-cuttings of 1861 gave an average yield of 29½ baskets per acre in circles where the Settlement Officer's crop-cuttings of 1884 gave an average of 20 baskets per acre. The average outturn, as stated by the cultivators for some of the circles, where fallow is most abundant and cultivation is slovenly, falls as low as 21 baskets per acre. The average yield assumed for the several classes of soil ranges from 25 to 40 baskets per acre; and these assumed rates have for the most

part agreed fairly well with the outturn rates actually admitted by the people.

On these data and on these assumptions the Settlement Officer has deduced revenue rates which represent one-half of the net surplus per acre after deducting all costs of cultivation and production. These rates, which range from eight annas to Rs. 3½ per acre, the Settlement Officer proposes for sanction as *maximum* rates. But he does not recommend that these rates be now enforced. He proposes that the rates actually to be imposed for rice-land should be 25 per cent lower, and should range from four annas to Rs. 2½ per acre, with a special Rs. 3 rate for lands in Pegu town. The reasons for advising these lower rates are detailed in paragraph 140 of Captain Parrott's report. For garden and miscellaneous cultivation the Settlement Officer proposes rates ranging from Rs. 3 to 1-4-0 per acre, but he advises a special low rate of Rs. 1 per acre for tobacco and sugar in order to encourage the production of these crops. He proposes also a special rate of Rs. 25 per acre for brick-fields, on the ground that land used for brick-making is destroyed for other uses hereafter. He advises a single rate of Rs. 3 per acre for all dhani-cultivation.

MR. A. B. FFORDE, of the Settlement Department, has addressed a valuable letter, on "Irrigation Works," to the *Times of India*; and as we agree generally in the views expressed by Mr. Fforde, we reproduce the letter below:—

I have read with interest your leading article on irrigation. The ryot is, as you say, in the habit of declaring that canal irrigation is not so fertilising as well irrigation. He says that the canal water is too "cold," requires more manure than that from wells. He does not say this of canals, from small streams, made by himself, but only of Government canals. The reason for his objection lies, I think, in the fact which I have often noticed, that he uses too much water when he takes it from Government canals, and water-logs his soil. Where the small village canals are used, he is restricted to a very limited supply of water, and gets no more than is absolutely necessary. His neighbours watch carefully to see that he takes no more than his proper share. Where the supply is practically unrestrained, as in the case of large Government canals, he keeps the water going all day and drowns out his crops. Again, since he can get much more land under water, he is tempted to spread his available manure over a large area, and compared with land under wells the crop is poorer in consequence. In the Deccan the ryot will often leave his well unused if he can get water from a local canal, because the labour is so much less. I imagine that, all expenses considered, canal irrigation, even if showing a poorer out-turn, is cheaper than that from wells—gives a larger profit.

As to deterioration of soil by canal water, that applies equally to wells. I have seen soil, formerly of the best, so ruined by well-water as to be perfectly barren. In the famine year I saw crops killed by water from wells. The smaller quantity of water probably caused concentration of the salts in the water-bearing stratum. If canal water caused the salts to rise from the lower strata where they generally lie, so does well-water, and in such strata the latter is even worse, because the water is drawn direct from the underlying strata and is not surface water like that from canals.

Where canal irrigation is impracticable, well construction would be of great value. Seven years ago I advocated, in one of the Bombay papers, the construction of wells by private capitalists in such districts. There is no doubt that wells could be constructed and hired to the ryots at rates which would pay very largely indeed. Such wells would be a most valuable property.

The comparative failure of Government canals to return large profits is, I think, due to the fact that many of them are not perennial. The people will not pay high rates for water, unless they can get it during the summer months, and some large canals are, as I know, unable to give water all the year round.

That the people are willing to use canal water is beyond doubt. In one taluka alone, in the Deccan there are upwards of 800 small canals from rocky streams. None of these can carry down anything but sand or stones on to the soil, but they are used wherever there is the slightest chance of making them. Well-water may be more fertilising, but very slightly so. It would naturally contain more earthy and vegetable matter from infiltration.

A FEW months back the President of the Municipality of Madras requested the Local Government to modify one of the conditions under which it is proposed to make over

the swamp known as Quibble Island to the Municipality for reclamation. Paragraph 3 of the order stipulates that "the lands should not be used for sewage farms or for the deposit of sweepings." The only material at the disposal of the Municipality for filling up hollows is street sweepings, and for the last twenty or thirty years this has been successfully used in reclaiming and raising numerous swamps and hollows in Madras. The reclamation is effected by digging pits or trenches into which the rubbish is shot, and it is then carefully covered with the earth or sand dug out of the pits. Portions of the Napier Park and of the People's Park were thus raised. The long stretch of land lying north of the railway line just outside, i.e., to the west of the Central Station is the most recent case of land raised by sweepings and irrigated by sewage. It has proved a distinct sanitary improvement to the neighbourhood, and indeed were it not so, the Agent of the Railway Company would no longer assent to the present arrangement. I do not see any likelihood of any sewage irrigation at St. Thome for many years to come, and then only in connection with a regular scheme for draining that suburb. But if the Municipality are to reclaim Quibble Island, it can only be by slow degrees and by means of street sweepings and rubbish. If the Government consider some precaution necessary, I would suggest that Government, on the report of their Sanitary Commissioner, should retain power to interfere and to require the deposit of rubbish, or irrigation by sewage, if any, to take place under such restrictions as they may think proper, or to stop it temporarily or permanently if they consider it desirable on sanitary grounds to do so. The following order was passed by the Government on the 24th March:—The proposals of the President of the Madras Municipality are accepted, subject to the condition named, and on the further understanding that the nuisance arising from the use of sweepings in filling in the swamp and sewage irrigation while the process is going on will be mitigated as much as possible by carefully covering the sweepings.

**

TEA fermentation is again exciting attention in Ceylon. The subject has already been exhaustively treated of before, but we take the following from the *Ceylon Observer* as illustrating the line of argument now adopted:—The subject is of increasing interest to Ceylon planters, but it is one which has engaged the attention and provoked the discussion of Indian planters for a very long time without any very definite result. A long controversy was started some years ago in our contemporary, the *Indian Tea Gazette*, on the subject of "fermentation," as to whether it was a correct term to apply to the process of discoloration which the leaf undergoes after rolling and before firing. Practical planters all then—and, we believe, now—agreed that the term was a misnomer, though this was combated by more than one chemist of ability, Mr. Chas. E. Russel, M.R.A.C., amongst others. The latter gentleman saw no reason to doubt the propriety of the term, inasmuch as the primary process necessary to the fermentation of all fermentable matter do undoubtedly take place in the leaf of tea after rolling, "though they are checked before the true fermentation has been effected." It was thereupon pointed out by Mr. Chas. H. Lepper, an Indian planter of experience, that Mr. Russell himself by the above assertion had practically admitted that *true fermentation* never existed in the leaf before firing, which checked whatever process was taking place in it.* Our correspondent "S." asserts, and quotes the *Indian Planters' Gazette* as upholding his theory, that, given a high temperature, dry leaf, and dry atmosphere, anyone can make good tea. But is this the experience of most tea-makers here? Is a dry atmosphere actually an incentive to rapid fermentation? Was it not found about this time last year, when the drought up-country was even more prolonged and pronounced than it has been this year, and the air was peculiarly free from moisture, that great difficulty was experienced in getting the leaf to ferment properly? Heat, of course, assists chemical action, but a dry atmosphere is also an aid to the process commonly called "fermentation"? We are inclined to doubt it. The theory that real fermentation never takes place in the leaf is further borne out by the fact that under suitable conditions, which cannot be difficult to determine, the roll is quite sufficiently "fermented" in three minutes

or so, whereas, conditions being adverse, as much as half an hour may be required. Is it possible that fermentation—using the word in its strictest sense—can set in in so short a time as a few minutes? The leaf undoubtedly commences to decay from the moment it is plucked. "Withering" is but the first step of this decay. By the process of rolling, the sap expressed from the leaf is brought in contact both with the *cellulose* forming the skeletons of the leaf-fibres and the oxygen of the air, but whether the effect of this is to cause fermentation proper to set up a violent chemical action which effects the tanning of the leaf, softening the liquor as a result, we must leave a chemist to decide. But it seems to us that the chemical change which takes place cannot properly be called fermentation, inasmuch as the process is stopped by firing when the *cellulose* has been turned into *glucose*, and before the latter is converted into alcohol and carbonic acid gas. We should be glad if some correspondents with chemical experience would give us the benefit of their views on this subject.

SILOS IN SOUTH AUSTRALIA.

THE importance of ensilage as a fodder is daily becoming more and more apparent. Wherever experiments in ensilage have been tried, they have resulted in a verdict in its favour over all other kinds of fodder. There cannot be the least doubt that in India ensilage bids fair to become a very important industry indeed, and as attention is now largely directed, not only by Government, but by private individuals, to the construction of silos all over India, we think any additional information on the subject cannot fail to be of interest to all concerned in ensilage experiments. The subject has attracted a great deal of attention in Australia, and its importance may be gathered from what Mr. J. L. Thompson, writing in one of the home papers, says that the wonderful results (recorded in almost every agricultural journal of the world) obtained by feeding stock with ensilage, must have brought the question home to every interested Australian—"Shall I construct a silo?" A very few years ago there was not a single silo in Great Britain, but at the present time there are 610, having a total capacity of 1,861,744 cubic feet, and representing about 34,000 tons of ensilage. Of these, England has 514, Scotland 60, and Wales 36. The largest silo is in the county of Argyll, and measures 60ft. long, 60ft. wide, and 16ft. deep, and has a total capacity of 57,600 cubic feet.

The same question must have occurred to many others, for we find that ensilage experiments are also being extensively made in Ireland, and the States of America have been, for some years, foremost in recording the results of the silo. It is somewhat remarkable that eminent scientific men have not taken a leading part in the matter of ensilage. On the contrary, they have thrown cold water on the subject, and not many months ago Professor Brown, of the Ontario Agricultural College, Canada, warned the British farmers not to be led away with the new-born ensilage.

Even the late lamented Dr. Voelcker, who so long filled the position of chemist to the Royal Agricultural Society of England, at first took a somewhat decided stand against ensilage. He afterwards, however, made many experiments, and came round to the opinion that the process of fermentation, or whatever it may be termed, gives considerable additional nutritive value.

Siilos were first introduced into South Australia some years ago by a Mr. Charles Rake, of Olive Farm, Enfield, and two years ago a Mr. John Bell, a large supplier of milk to the city of Adelaide, constructed a silo which was opened for the first time at Christmas, 1883. Mr. Bell says that before he commenced using ensilage, his cows were drying up so much that he could not procure nearly enough milk to supply his customers. But ten days afterwards, although no addition in the number of cows, he could not dispose of all his milk, so great was the increase, and the quality also much improved. He was convinced that nothing could equal ensilage for milch cows.

The proprietors of the Beaufres estate, South Australia, being thoroughly convinced that the use of the silo would assist

them considerably in keeping the stock in a progressive condition, and in supplying succulent food during the parched summer months, decided to construct a silo, consisting of four compartments, each 20 feet long, 12 feet wide, and 15 feet deep, having a total capacity of 14,400 cubic feet, and capable of storing 300 tons of ensilage. The walls consisted of lime and gravel concrete, and were plastered over inside with cement. There were two feet of dry pebbles below the walls, and from this an outlet to a low level, where any liquid that may accumulate could be run off; while Special attention was drawn to the moveable doorways, which were found to be very convenient in more respects than one. In removing the ensilage, instead of having to haul the stuff up 15 feet, by removing the moveable planks it saved a haulage of 5 feet.

But those who are unable to have a substantial construction, need not be debarred from giving the silo a trial on a cheap scale. A hole simply dug in the clay and covered over with loose sheets of corrugated iron filled with ensilage has been found to preserve just as well as in the silo of more architectural pretensions.

One of the proprietors of this estate gives the following as the mode adopted in filling their silo: We commenced filling the silo with a mixture of Cape barley, rye, and vetches. The reaper and binder commenced cutting early in the morning. Buncle's large travelling chaffcutter was put in position so that the stuff was elevated over the wall and fell right into the pit. The motive power was supplied from a portable steam-engine. The paddock was close handy to the silo, but it required three farm waggons to keep the machine going. With good steady work we managed to fill one pit in two days, and immediately on completion all hands turned to and put the planking and weights on as quickly as possible. The weighting used was good-sized boulders from the bed of the River Torrens: these were put on 2ft. thick all over the surface, this being equal to a weight of 2cwt. to the square foot, which is considered the proper weight by those who have had experience in the matter. When everything was fairly started, the work went on like clockwork, as the saying is, and on the afternoon of the eighth day the whole of the four pits were filled and weighted down. I should mention that a heavy Clydesdale was put into each pit (as soon as possible after a start was made), and kept moving round and round until nearly full. During the first few nights the shrinkage was very considerable, but after the first week no perceptible fall was observed, and on an average the stuff had gone down about 3ft. I am of opinion that fermentation goes on for about a month, and before the end of that time the ensilage would not prove palatable for stock. It is much improved by being kept three or six months, and at the end of 12 months, it has been found to be in first-class condition. Owing to a heavy crop of maize maturing for the silo, we were compelled to commence our ensilage much earlier than we otherwise would have done. We opened our first pit, which had only been put down a little over a month, and found the ensilage thoroughly preserved, having a slightly acid and vinous smell, which is not by any means unpleasant. When it is exposed for some time, it has the smell of apples. After all, however, the impulses of the cattle who are offered it are the best tests of its quality, and after a little snuffing round the trough, all ours commenced to eat it greedily.

This points to the necessity of not opening silos too soon. If the above-mentioned silo had been allowed to stand over for 12, or even 6 months, the acid vinous smell would have been absent.

In support of the argument in favour of ensilage, it is stated that cattle assimilate it better than any other food, the reason being that the change effected in the silo is akin very nearly to that which takes place in the first stomach of ruminant animals. One fact was patent, that cattle have been found to take to ensilage readily, and thrive wonderfully on it. Its effect on milch cows in Australia is said to be marvellous. In one instance, it was found that some cows, which had been in milk for 8 or 9 months and were beginning to dry up, when supplied with ensilage, commenced to give a quantity almost equal to a new-calved cow. This may be slightly

exaggerated, but it has been ascertained beyond doubt that ensilage is peculiarly suited to milch-cows.

Mr. Thompson furnishes the following very useful and practical hints for the construction of silos as adopted in Australia:—

The Construction of the Silo.—Local circumstances must determine what material can be most economically used for the construction. When plenty of good river gravel can be procured handy, nothing in my opinion can excel concrete of this material, being most substantial, and procurable at a trifling cost. It is not necessary to use cement in the construction of the walls; one part of good lime to four parts of gravel will make a good wall, but to give a better surface to the inside of the walls, it is well to plaster these over with one part of cement to two parts of clean river sand.

The Beesacres silo division walls are 2 ft. thick; this is necessary to prevent lateral pressure from the division of the silo that may be filled first. The outside walls need not be so thick, as being built close to the clay bank lateral pressure can have little effect on them. Indeed I am of opinion that there is very slight lateral pressure, the cut fodder, being of a green, sticky nature, has not the tendency to burst out, as would be the case with wheat or water, for instance.

The Best Crops to put in the Silo.—I am strongly of opinion that anything of a succulent, green nature can be thoroughly preserved in the silo, and rubbish, such as cock-spurs, variegated thistles, wild oats, &c., that stock would not care to eat (unless very hungry), can be much improved in the silo, and when presented to the cattle, will be devoured with much relish. We tried an experiment with part of one of our silos as above, and were astonished at the result. If once a silo is erected, nothing on the farm can grow that cannot be put to profit and good account. As general crops, however, for the silo, nothing in my opinion can equal rye, vetches, and barley mixed for the first filling, and maize for the second. By liberal manuring and good cultivation, two heavy crops of the above can be procured in one year from the same land. Early in April, after the first rains, we sowed our barley and vetches, &c. This magnificent crop was fit for the silos about the middle of August; but as our silo was not then ready for its reception we had to fall back on a later sowing, and, as before stated, filled our silo early in November. I have said, however, that we had a magnificent crop of vetches, rye, and barley ready for the silo about the middle of August. The land can be immediately cleared of this crop, as there would be no time lost in waiting for the drying of the crop, and the land could be got ready in time for the planting of our maize in September, and this crop can be successfully grown even in a very dry climate. During the growth of our maize, from September 13, 1884, to January 7, 1885, only 4.672in. of rain fell, and notwithstanding this small quantity, the crop all over was fully five feet high, and would average about 15 tons per acre. If water was available for irrigation, 30 to 50 tons of green maize could be easily grown.

The Advantages of the Silo.—Anyone seeing a magnificent crop of green, succulent vetches, &c., in the spring of the year would have, doubtless, expressed a wish that it could be maintained throughout the year. Now this is exactly what the silo will do. So soon as a crop of green fodder has come to its best, put it away in the silo, and it will not only maintain its good qualities, but actually improve, and in the many arid districts of Australasia during the hot summer months, when there is not a green blade to be seen, every farmer can have abundance of nutritious food at a trifling cost. Especially to owners of shorthorn herds, whose stock are sometimes retarded in their growth during the summer months for the want of good succulent food, would I recommend the use of the silo. Expensive artificial feeding has often to be resorted to which could be wholly dispensed with by its use. No system of preserving fodder can equal it; there is no waste, no shrinkage, and the mass comes out as it went in. One acre of land, if properly utilised, will give ample food for a milch cow for 12 months by growing two crops, as before mentioned, and the animal being kept under what is known as the soiling system, the whole of the manure could be returned to the land annually.

Miscellaneous Items.

DURING the month of February 435,012 cwt. of wheat, valued at Rs. 18,53,492, were shipped from ports in Sind.

THE Indian Paper Mills Co., Ltd., is busy erecting the factory at Kurruckwasla, and hopes are entertained that the mills will be in working order, in three or four months' time.

THE liquor trade of Rangoon seems to be making immense strides, if we may judge from the fact that all the godowns of the Custom House are full of liquor, and nothing but liquor.

ELEVEN and half tons of compressed hay were despatched by train lately, to Madras, for consumption by the horses of the Field Battery of Artillery ordered to proceed on field service to Quetta.

MANGOES will be exceedingly dear this season, writes a Goa correspondent, for very few trees have flowered, and in those which have, the blossoms have not all set, having been destroyed by dew.

THE Government of Madras have sanctioned an estimate, amounting to Rs. 2,07,000, for restoring the Red Hills tank of the Madras water-supply and irrigation extension project, including establishment and tools and plant charges.

THE Chief Commissioner of British Burmah distributed the other day medals and prizes to Burmese artists at the Art Industrial workshops in Godwin-road. The exhibits in this provincial art competition now being held at the workshops are well worth viewing.

A GOVERNMENT Resolution has been published, excluding the Crown Preserved Coal Company, of Cardiff, from all tenders for the supply of coal to Government, in consequence of a gratification of £50 having been offered by the Company to Major E. Marryat, Manager of the Punjab Northern State Railway.

It will be sad news for those who have a partiality for mangoes to know that the crop this year will be unusually small. It is supposed that the shoots thrown out by the trees at this time of the year have had to do with the failure of the crop. It is, however, gratifying to know that with a small crop of mangoes, there will be a large crop of health, which an over-indulgence in this fruit never failed to impair.

FROM the report of the Horse Show held at Rajkot in December last (for a copy of which we are beholden to the Under-Secretary to Government), it appears that the show was somewhat disappointing, both as to the number and the quality of the exhibits. With a few exceptions, the animals are reported to have been "very inferior." The Political Agent, Kattywar, makes a suggestion for the future, which Government have adopted. They ask for future suggestions, too, which, we hope, will be made in time for next year. Though comparatively unsatisfactory, the Horse Show last year was by no means a failure.

THE Manager, Devala Moyal Gold, reported on February 23: "Salomon's Reef: We are carting quartz to the mill taken from the rise up between the 200 and 300 ft. levels. This crushing will consist of 120 to 150 tons, and it will, I think, turn out fairly. The old tunnel has been driven 80 ft.; 140 ft. level, 16 ft.; rise up from same, 3 ft.; 200 ft. level, 7 ft.; 300 ft. level, 3 ft.; 300 ft. level, 2 ft.; 500 ft. level, 23 ft. The 400 and 500 feet levels are directed to drive upon what appears to be the eastern leg of the reef. The former contains payable quartz and a well defined reef; the latter has only just been commenced, and has not touched the reef as yet. —Harewood Reef: The drive south along the course of the reef has been extended 3 ft., but there is no other change to report."

A POONA paper says: "Madras has tried our East Indian Colony with success. Bengal has such an institution in hand, and as the Government is reported to be in favour of the movement, it will at an early date be undertaken and carried out. But, what of Bombay? Is it to remain altogether in the background? What is the European and Anglo-Indian society doing? As Bangalore was found just suited for such a colony in the Madras presidency, and Darjeeling in that of Bengal, so Poona, for the Bombay presidency, offers facilities which no other station can. There are several farms, at the present time, owned and worked by East Indians, and with excellent results, after years of trial. The establishing of such a colony here would prove a boon and a blessing to the Government, no less than to the community at large. Such a colony will be hailed as a great blessing."

CAPTAIN B. D. PLUMMER reported on February 24: Mining Operations: The lode in the north end at the bottom of the mine appears to be getting smaller. This we might have expected as the run of ore ground dips north, and we have been working close upon the north point of the ore. The south end, at the bottom of the mine, looks very fine, and the rock is somewhat easier to cut. The lode in the bottom of shaft, as far as we have taken down, look very healthy and strong:—173 South End on the West Lode: There is still a width of 3 ft. of quartz by the side of the old work.

lugs. How far it will hold, it is impossible to say; it appears to be made up of branches left by the old men. The last assay value, which was made on the 29th instant, was 2 ozs. 16 dwts. 8 grs. per ton of quartz. The winze in the bottom of this level has cut through the arch, and now it is in "attle" or dead, that the former workers had packed in to keep the sides open.

A CORRESPONDENT at Yeroaud, Shevaroy Hills, writes to say: "A very peculiar noise, the cause of which is as yet undivined, was heard on various parts of these hills this morning about 8 A.M. It sounded somewhat like distant thunder, but the sky was quite cloudless at the time; the noise lasted for about 40 seconds or more, and died away gradually. An earthquake was the first thought that suggested itself, but no tremor of the earth was felt; it seemed to come from an easterly or north-easterly direction. The noise was too prolonged for an explosion of an ordinary nature, and died away too gradually, though somewhat sudden in its commencement. It would be interesting to know if it was heard in other parts of the country. I was five miles from Yeroaud when I heard it, and on return here I found it had been distinctly noticed here also, and an earthquake was expected, but as to its origin, we are all puzzled."

THE Straits Settlements Emigration Act, No. V. of 1877, having been repealed, and migration to that colony being now regulated by the Straits Ordinance, No. 5 of 1884 ("The Indian Immigration Ordinance, 1884"), his Excellency the Governor in Council proceeds to lay down rules for the guidance of officers who will be concerned in carrying out and superintending such emigration. The District Magistrate of Tanjore, the Port Officer of Negapatam, and the British Consular Agent at Karikal, will be appointed to be Emigration Agents for the purpose of these rules. The District Magistrate will submit to Government the name, or names, of such officer, or officers, as he may recommend to be appointed Registering officers for the purposes of these rules, and these officers will then be so appointed and invested with powers under the Native 'Passengers' Ships Act. The officers concerned are requested to carefully watch the working of these rules, and report at the end of the year whether they are found to be suited to the objects in view, or in what respects they need to be modified.

At the end of the official year 1883-84 there were 21 jute mills at work throughout India, giving daily employment to 47,868 persons, of whom 26,494 were men, 10,331 women, 6,348 young persons, and 4,895 children. All but two of the mills are in Bengal, most of them near Calcutta, one of the others being in Bombay, and the other at Vizagapatam. Both of these, however, are very small concerns. The two first mills were established in 1864; between that date and 1872 three more were started; from 1873 to 1875, seven more were established; six came into working between 1876 and 1880, and three more have been started since 1882, so that the industry may be said to have grown up entirely within the last twenty years. The mills at present at work contain 6,139 looms, 112,650 spindles, and worked up, during the year, about 142,000 tons of jute. But these figures cannot be entirely relied upon. The same may be said with regard to the nominal capital of the mills, although those that are worked by Joint Stock Companies return their capital at 20 lakhs. No return of capital is made by eight out of the 21 mills, as they are worked by private firms. It is estimated that about 65 or 70 lakhs may be taken as the capital of these private mills, which would give a total capital of about 270 lakhs invested in the jute industry.

Selections.

THE PREPARATION OF COCA.

READ—the following letter from M. A. LAWSON, Esq., Director of Government Cinchona Plantations, Parks and Gardens, Nilgiris, to the Secretary to Government, Madras, Revenue Department, dated Ootacamund, 18th March 1885, No. 522:—

WITH regard to the questions relating to the preparation for commercial purposes of the leaves of *Erythroxylon coca*, continued in G.O., dated 17th February 1885, No. 207 Revenue, I have the honor to forward, for your information, an extract on the subject taken from Bentley and Triumen's Medicinal Plants, volume I, 40:—

"Much care is taken in the gathering, drying, and preservation of coca, as its activity and value depend in a great measure on its mode of preparation. Some differences in detail occur in the collection and preparation of coca in different districts, but, as a general, rule the processes are as follows:—The leaves are gathered as soon as they have arrived at maturity, at which period they are bright green on their upper surface and yellowish green on their under surface, and have an agreeable and somewhat aromatic odour. The leaves are gathered separately and carefully by the hand, with the two-fold object of preventing them being crushed or bruised in the process; and also so as not to injure the young leaf-buds which are left behind, for the purpose of obtaining a second crop of leaves. They are then carried away in baskets and

spread out on paved surfaces or on the floors in the courts of the houses, or sometimes on woollen cloths, and dried slowly in the sun. This operation requires great care, for if the leaves be dried too rapidly, they lose their odour and green color, and, if stored away before they are thoroughly dried, their color is also changed, and they acquire a disagreeable odour and taste. In some districts the leaves are occasionally trampled over while they are damp, under the impression, it is said, that they thus acquire a delicate flavour and smell, but also probably to preserve their flatness in the drying process. After being dried, the leaves are either stored in barns or huts, or packed in bags or bales, in which they are pressed by treading, and are thus transported to a distance. These bags or bales (*costas*) appear to differ very much in size, their weight being variously given by authors at from 24 to 150 lb. As the properties of coca are injured by transportation, and often by keeping, it would probably be best preserved in cases or packages lined with tin, or at least in well-closed pots to protect it from air and moisture. The produce of coca per acre in a good harvest is estimated by Weddall at about 900 lb., and in some districts there are three or even four harvests in the year. The total produce of coca is probably not less than 40,000,000 lb., which, estimating the value on an average at the low price of one shilling per pound (for the best qualities yield at least five shillings) in the countries in which it is produced, would represent a total value of £2,000,000, so that coca is by no means an unimportant article of commerce, and its production is, moreover, described as being very remunerative. It is chiefly exported from Lima."

2. From the above extract it will be seen that the chief points to be attended to are—

1st.—The rapid drying in thin layers of such leaves as are fully developed and are yet not too old.

2nd.—The immediate packing of the dried leaves in air-tight boxes.

3. Those who possess and desire to harvest leaves for sale in England should experiment on small quantities in different ways until they arrive at a satisfactory result, and to this end I would recommend them to proceed as follows:—

(1) Pick the leaves early in the morning.

(2) Spread the leaves out on some smooth surface, such as boards, so that there should be—

(a) One layer of leaves.

(b) Two layers of leaves.

(c) Three layers or thereabouts of leaves.

(3) Select a place for drying the leaves which is exposed to the sun, and if the leaves curl up or turn brown, try different degrees of shading.

(4) Pack the leaves tightly as soon as dried in layers in tin or other air-tight boxes.

4. Mr. Hooper experimented upon a sample of leaves from plants grown at Buriyar; from these he extracted a 2 per cent. crude alkaloid. Some of this was given to Dr. Bidie, who handed it over to Dr. Brockman for trial, and Dr. Brockman has pronounced the compound to be worthless. From this, however, nothing more necessarily follows than that the leaves were improperly selected or improperly dried, or that the necessary chemical processes in extracting the alkaloid were not observed.

5. Mr. Hooper will be shortly engaged upon fresh experiments, and, when these are completed, they shall be communicated to you.

UTILISATION OF PEAT SWAMPS IN INDIA.

It is not a little surprising that the numerous peat bogs which form so distinctive a feature of the Nilgiri plateau and other Hill ranges in India, are left in undisturbed possession of the snipe and moor-fowl, and that no attempt is made to win from their turfy depths the wealth which only needs the enterprise and mechanical ingenuity of the energetic European to realize it. The mechanical preparation of raw-peat for use as fuel is a branch of industry which has been brought to a high state of perfection in Australia, America, Scotland, and other European countries, and there is no reason why it should not prove a success in India. The importance that attaches to the development of this source of industrial wealth may be estimated by the extent of waste bog, now useless, that would at once obtain a high value were the raw-peat, which the swamps yield abundantly, manufactured into that valuable product, peat-coal. From various measurements made, it is found that the average depth of bog on the Nilgiri is 9 feet, and this depth would give 11,250 tons of raw-peat to the acre; and allowing 6 tons of raw-peat to yield one ton of peat-coal, the produce of peat-coal per acre would be 1,875 tons. It is true that an isolated experimental attempt, made some years ago, not only to manufacture good cheap fuel, but also to utilize other products of peat, resulted in failure; but this ought not to paralyze further action, because failure resulted from defects not necessarily connected with the enterprise itself, but rather with the means employed to carry it out. Similarly, the first attempt at the mechanical preparation of peat-coal in Australia was not attended with success, on account of the imperfect and costly means employed in its manufacture.

Bog-peat is decayed vegetable matter in a state of transition towards coal by the natural operation of time. It exists in various

stages of decomposition, according to locality and age. Peat prepared in the ordinary way for fuel is of two kinds. One is cut and spread out on the bog surface, in the first instance, to dry; then collected, and set up endways in small heaps, preparatory to being carted home, and stacked for use. The second kind is much superior, though more expensive to make, than the "cut-turf." It is made out of the black peat taken from the bottom of the bog, worked up into the consistency of thick mud, then spread out on the bog surface, to the depth of six inches or so, and shaped off into bricks for drying. This turf, when properly made, and effectually dried, is very hard, and in quality superior to any preparation in the ordinary way. But even the best turf, when air dried, under favorable circumstances, seldom contains less than 20 per cent of water, and this detracts proportionally from its value as a heat producer, because so much of its caloric is wasted in evaporating the large percentage of water it contains. Now the solitary attempt to which we have alluded to manufacture peat for fuel, &c., on the Nilgiris, was attempted by means of mechanical compression, and the same mistake was made during the inauguration of the industry in Australia. To this end ingenious machines were designed in the latter country, and it was from no want of inventive genius or mechanical skill that the principle of compression failed in practice. Admirable appliances for the purpose were designed to squeeze the water out of the peat, thereby rendering it dense and solid, so as to be more easily dried—and more valuable when dried—because it would contain thus prepared a greater amount of heat-producing material in a smaller bulk. But the process was found not only faulty in principle, but also hopelessly expensive. Ordinary peat when cut in the bog may be taken to contain 90 per cent of water, so that a machine would have to squeeze some five or six tons of raw peat to produce one ton of comparatively waterless compressed peat. Thus a great expenditure of mechanical force is involved, and this force cannot be brought into action without a corresponding expenditure of water or steam as a motive power. Moreover it was found, after much spirited enterprise, that even with the employment of enormous pressure, perfectly solid and waterless peat-coal could not be obtained by compression and subsequent air drying.

It was discovered that the most economical and perfect way by which raw-peat could be manufactured into peat-coal was as follows: The black bog stuff, which is thoroughly decomposed peat, and consists of very minute particles, is puddled well together with a due admixture of water, and passed through a very fine sieve. This is submitted to the process of drying, and the particles possess an adhesive affinity, the effect of which is to combine them together in one solid mass, analogous in density and hardness to ordinary coal. In this way a substance is obtained far superior in delicacy of grain and hardness to the latter. The peat particles thus treated, become fossilised, as it were, so much so indeed as to equal the petrified organic matter known as jet. This jet like peat-coal is susceptible of being worked as jet. It will take a very high polish; can be turned into a table, and converted into various articles of beauty and utility such as vases, cups, &c. The surface peat of a bog can also be treated in the above manner by macerating the raw-peat in water, and allowing the pulpy mass to drain by subsidence, when the particles by a natural cohesive affinity unite and solidify.

As regards the commercial value of peat-coal, it has been proved a most efficient and economical substitute for ordinary pit-coal, and in many respects is much superior to the latter. It is extensively used in working locomotives on Australian and American Railways. The cost of manufacturing peat-coal for the Grand Trunk Railway of Canada, where wages run high, is under 5 shillings per ton, while it possesses a heating power equal to good pit-coal in the proportion of five to four. One ton and a quarter of peat-coal is equal to one ton of the best English pit-coal for ordinary steam boilers, &c., but for household purposes and for furnaces having little draught, and with the firebars close together, one ton of peat-coal is equal to the same quantity of the best Newcastle coal. The additional advantages of peat-coal are that it can be used for all purposes for which pit-coal is used, while it does not emit any smoke, contains no sulphur or phosphorus, gives a bright clear fire, and causes no injury to boilers, flues, &c. For iron works, manufacturing and railways, it is specially valuable. The smoke nuisance, which is a great evil in itself, is avoided by its use, while its cleanliness and high caloric power renders it peculiarly valuable for domestic use. In Australia it is calculated that when pit-coal is 20 shillings per ton the proportionate value of peat-coal is 16 shillings, and its cost of production about 6 shillings per ton. It thus yields a return of the capital employed of 200 per cent. This profit is not speculative but warranted by practical experience. With the cheaper labour of India a greater profit could be realized.

Peat-charcoal is another product of the bogs much more valuable than peat-coal and much more costly to manufacture. But if we consider that in its manufacture other important products of the peat are obtained, such as tar, sulphate of ammonia, oil, paraffin and methylated spirits, the production of peat-charcoal is comparatively costless. As this charcoal, like the peat-coal, does not contain any sulphur or phosphorus, it is invaluable for the manufacture of steel, bronze, copper and all metallic substances—particularly for cutlery—gun-making, electro-plating, and also for the manufacture of porcelain and China-ware, and for a few purposes where wood charcoal is used. The facts leave no room for doubt concerning the highly remunerative character of the manufacture of peat-coal, &c.; while no question can arise respecting its vast importance as a source of industrial yet undeveloped wealth. Indeed, when we consider that the peat on the Nilgiris and other hill ranges of India is practically inexhaustible, its utilisation on a sound, scientific, and remunerative basis becomes a matter of national interest.—*Madras Mail*.

THE MAINTENANCE OF DAIRY STOCK.

(By PROFESSOR SHELTON.)

THERE has been a good deal of discussion in recent years respecting the extension of dairy farming in tillage districts, and the term 'arable dairying' has been adopted to distinguish the so-called new departure or development in dairy husbandry. It is probable that the topic received a considerable share of its impetus from the articles on Continental dairying which, appearing in the *Journal of the Royal Agricultural Society* and elsewhere, were written by Mr. H. M. Jenkins, the talented and indefatigable secretary of that Society; yet the low price of grain for many years past, together with the depression which has ruled so long in sheep farming, both of them intensified by the wet seasons which have passed over us, and these, in contrast with the comparatively profitable character of milk-selling and stock-raising, have had still more to do in attracting arable farmers' attention to this particular aspect of dairy farming. It is no doubt true that this extension has been going on to some extent, accompanied by the laying down to permanent pasture of a good deal of arable land suitable to the purpose, but there is not much probability of the extension being continued to any very striking extent.

Permanent grass land is, as every one knows, a leading feature in the dairy farming of the British Islands, though more or less of arable land is usually found associated with it. Our humid and irregular climate accounts for the prevalence of grass land, and particularly for its extension in recent years; and in view of this climatic disability, together with the fact that dairy farming may easily be extended too far, and, indeed, has already been extended too far, to yield a profit very much superior to that of other branches of husbandry, it is to be feared that the laying down of arable land to permanent grass will go on still in places in order to lessen expenses. It does not at present seem so much desirable that dairy farming should invade purely arable districts farther than it has done already, as that arable cultivation should be restored and developed in dairying districts. Notwithstanding the costliness of arable cultivation, a proportion of arable land is, generally speaking, an element of profit and convenience to dairy farmers, and cannot very well be dispensed with, save in highly-favoured localities. In some parts of France, as also to a less extent in one or two other continental countries, permanent grass land is almost entirely dispensed with by many dairy farmers; but a practice such as this is the growth of many years, and cannot in one generation be successfully engrafted on a different system of agriculture. The chief obstacle, perhaps, lies in the farmers themselves, rather than in the land they occupy and the climate under which they live.

It remains to be seen whether the practice of ensilage will become general and permanent on dairy farms in these islands. For my own part, I hardly think it will; and whether, if it does, it will materially affect the current proportion of grass and arable land. We may decline to accept the enthusiastic claims which some persons advance in favour of ensilage, as well as their predictions that it will revolutionise the practice of dairying, and we may incline to the opinion that, so far as the maintenance of dairy stock in winter is concerned, the most it will do will be to take the place of roots and brewers' grains; but, whatever we do, it is clear that it has taken a great hold on the imagination of the farming public, and that it is being experimented with in earnest in most parts of the country. Forage, that is ensilaged instead of desiccated, cannot reasonably be supposed to be better than it was in its green and natural state, and we may dismiss the idea that almost any kind of coarse and inferior stuff, such as the grassy undergrowth of trees, and various kinds of green crops that are not palatable or nutritious in their growing state, are greatly enhanced in value by being confined in a silo for a few months, yet is there one substantial advantage which well-preserved ensilage possesses over the hay, for instance, that might otherwise have been made from the grass, viz., it remains in a succulent and easily digestible condition. It is on this ground, indeed, that ensilage will become popular and general, if it does so at all.

We may take it for granted that permanent grass land, used as pasture, will in our time continue to be the chief source of the maintenance of dairy stock, except in the winter months, and it is not at all likely that the French practice of 'soiling'—that is, of cutting grass and other green crops for consumption in yards and sheds and byres—will become very general in this country in the remaining months of the year. Rather than this, the American practice of soiling on the pastures with adjoining cultivated green crops, which is an old though limited practice here at home, is likely to become extended in connection with arable dairying, on land that lends itself with advantage to the cultivation of such green crops. It would seem probable that the growth of vetches, clover, and so on, for the purpose of soiling on the pastures in spring and summer and autumn, might in many localities be profitably extended with the view of supplementing

the pastures; and a properly adjusted proportion of arable land, used for this purpose of soiling, would enable a large number of cattle to be maintained on a given farm. The object to be aimed at is the production of a maximum quantity of food for stock, in a manner which leaves a substantial profit; and, in order to do this, a well-balanced proportion of arable land, harmonising with a staff of men and horses, would seem to fit in well with the etymology of the term 'arable dairying.'

It is winter, however, rather than summer, the provision for which taxes the ingenuity of dairy farmers, for that is the period in which the maintenance of dairy stock is felt to be a burden both in cost and labour. It is winter, indeed, which lends the chief importance to arable dairying, because of roots and straw, and ensilage, too, if you will. To winter a herd of cattle on hay alone is a practice ill calculated to be profitable, and this aspect of the case is well understood in districts poorly adapted to arable cultivation. On a wholly grass farm there is not work enough for the hands who are required to milk the cows, and it is only on a farm that is partly arable that the labour bill can be properly filled between times, so to speak, in all the seasons of the year. In some localities it is feasible to hire women for milking only, at a reasonable rate, and in these cases, a smaller staff of men can be kept on farms whose area of arable land is too limited to keep a full staff in work. This labour question makes itself seriously felt in these days, and it has a distinct and immediate bearing on the employer's profits. Hence it follows that farmers in many cases have been tempted to lay down land to permanent grass, with the object of cutting down the labour bill, which, it is obvious, can only be done within limits. This it is, too, that has induced so many grass-land farmers to give up dairying, and take to the fattening of stock in summer, in the hope of doing with a minimum of labour and of wear and tear of implements.

The wintering of a herd of dairy cows, and of its necessary relay of young stock, is felt to be a serious matter, and it appears all the more serious when the cows are mostly dry for calving. This unpleasant feature of the case, together with the opening supplied in recent years by the milk trade, has led to a considerable extension of 'winter dairying'—that is, the production of milk in winter. But this has found its limit during the winter out of which we are just emerging, and milk has been cheaper, and more plentiful than ever before, at that season of the year. The cost of producing a full supply of milk in the winter months is best understood by those who go in for that sort of thing, and it may be said that a great deal of last winter's milk was produced and sold at a loss. This will cause a reaction against winter dairying to some extent, but dairy stock have to be maintained all the same. The entire thing has to be kept well in hand by the master, and economy of feeding must be introduced wherever it is possible, for we live in times when close cutting is the order. Store stock, milk, cheese, butter—all of them are at low values, and likely to be for some time to come; and in this event the efficient and economical maintenance of dairy stock is a matter of greater importance than it was ten or a dozen years ago, when the profits were good enough to support any reasonable system.—*North British Agriculturist*.

PREVENTION OF DISTEMPER.

I HAVE lost two young collies lately from distemper, and have another, six months old, which I should not like to lose. Can I do anything to prevent the attack or to lessen the force? The puppy has freedom to run about all day, has a good dry bed at night. His food consists principally of porridge and milk, with an occasional bone or other scrap.—J. C. B.

[The better-bred dogs are most liable to distemper, and suffer from it most seriously. Amongst young collies it often does deadly damage, and many which survive the attack continue long, or even permanently, the subjects of chorea fita or partial paralysis. Like other febrile disorders of young animals, distemper is notably contagious, and it probably does not, like colds, coughs, gastric derangements, or other such disorders, arise spontaneously or from insanitary conditions. Prevention is hence secured by protecting dogs from contact with sick or convalescent subjects. Dogs, however, are prone to roam freely on their own account, and it is accordingly difficult to isolate infected animals, and those that have been in contact with them, and thus prevent distribution of contagious germs. With the view to protect from attacks and diminish their severity, young dogs have been inoculated with vaccine lymph; but vaccination has not answered the expectations formed of it as a preventive of distemper. Investigation may yet discover, as in the case of anthrax diseases, that a modified form of the disease may be produced by cultivated lymph, and that young dogs inoculated with it may resist the ordinary unregenerate distemper. Like the contagious eruptive fevers of children, and especially measles, to which it is closely allied, it seldom occurs more than once in any individual. Besides protecting from contagion, preventive treatment is limited to maintaining young dogs in good general health, and when the disease prevails in a neighbourhood, giving the puppies in their porridge, soup, or other food, twice or thrice a week, 4 to 8 grains of hyposulphite of soda, which, being almost tasteless, is readily taken, and from its antiseptic properties lessens the severity of febrile disorders, and sometimes even protects from their attacks. In kennels, and other places where distemper has occurred, the contagious germs are apt to remain with unimpaired activity for a long time, and hence it is very essential that wherever infected subjects have been kept, repeated thorough disinfection should be adopted.—*Vet. Rec.*]

INDIAN SILK.

TO THE EDITOR OF THE "PIONEER."

SIR,—Your article on the Bengal silk trade is before me, and I think that the writer is rather severe on Bengal silk in particular, and casually so on Punjab silk, and he also seems rather hazy as to what reeled or raw silk and thrown silk is. I have the pleasure to send you by sample post, a small skein of raw silk from my miniature filature (from Barthand's Lyon), and beg to inform you that it was produced here under my own supervision from cocoons reared in my own sheds. Cocoons of equal quality are produced by careful rearing in this and the neighbouring district of Goordaspore; the mulberry of every kind grows up here to perfection; silk reelers are to be got who will do good work at a moderate wage, and I have been engaged, with the help of the district authorities, Colonel G. Gordon Young and Colonel C. V. Jenkins, in encouraging the industry of sericulture for over two years. Hitherto it has thriven wonderfully well with me, and the above-mentioned gentlemen will be very sorry to read your degrading article without some contradiction possibly, or partial fight, for the pretension of the north of the Punjab to produce good "bone" silk. Perhaps if the writer of the said article took the trouble to glance at the map of the world, he would find that the north of the Punjab and the part of China and Japan where the best and strongest silk is produced, lie just above the 30th paral. of N. Latitude. Perhaps also, this is the reason why I have found the Japan silk-worms thrive so well with me, that the reports from several centres in England, Italy, and France are that the cocoons cannot be excelled in the world, and probably also the reason why I obtained a Silver Medal and 1st Class Certificate at the Calcutta International Exhibition for a very small case of cocoons, when a gentleman and silk expert, who tested them and the silk reeled from them, reported them second to none in the world. My silk sent to you may have many faults, as I have been reeling less than six weeks and with last year's cocoons; but I am open to learn if you can give me any information regarding it, and I shall be obliged, therefore, if you will kindly test it, and let me know whether or not it is a good "bone" silk. I myself believe that this part of the world will produce the best silk, and with capital I could produce a quantity that would command a very good export price; and I should be glad to hear of any one with capital who would join me in increasing my outturn. It already pays me to produce it and reel it at the present low price of silk, which, on account of the Franco-Chinese war, is the lowest ever known. The reason why the silk industry is not flourishing in the Punjab is not because the climate will not grow good silk, but because the native is so lazy and trusts so much to his gods to give him a good crop of cocoons that the worms die of hunger and dirt, and disease, the companion of the latter—and they will not plant mulberry near their own doors. It ought also to be pretty well known by this time that the rearing of the silk worm to produce good cocoons is a matter of considerable difficulty, unless patience and perseverance, to say nothing of a certain amount of intelligence and cleanliness are exercised, and that the consequence is that good silk being difficult to produce, a good price is always obtainable for it where good silk is used and wanted, and there is always a demand for good silk. The fashion now-a-days is to try and get things cheap and vile, viz., plush instead of velvet, &c., &c. Cheap things can be spun from pushum or waste silk, from waste cocoons and from wild silk, very few of which can be reeled so as to pay, on account of the difficulty of softening them, and of their open ends, and also of the difficulty of collecting them in sufficient quantity.

Spinners in Europe are making fortunes out of waste, it is true, and are always crying out for these wild silks which are known to be used by natives in certain districts; and they imagine they will be able to encourage old *Bombyx Mori* out of the field. This they will never do. Nothing has yet been able to hold its own against the *Bombyx Mori*, either in silkworms or other textures, and I believe that though wild silks may be used to a small extent, a good Japan cocoon can be produced in the Punjab, and as good silk from it, as any in the world and as cheap, always remembering that a good article in silk is always dear for reasons that are well known, and which have lasted for hundreds of years in spite of every endeavour to the contrary.

ERNEST R. BARTLETT.

Palumpore, Punjab, 3rd April 1885.

WATER THE COWS.

The following data, though not sufficiently exact to be called scientific, are of some practical value in enabling farmers to judge of the effect of watering cows regularly and often, and in not doing so. Since January 1, we have been milking an average of about 24 cows. The majority of these cows calved in March and April, 1884. We therefore expect a shrinkage, as previous months show, of about 30 pounds per day. Suppose the average for December had been 370 pounds per day, we would expect the average for January to be 340 pounds per day. During 15 days in January we obtained 5,426 pounds, or an average of 339 pounds per day. From the 15th to the 18th inclusive, the average was 320 pounds per day. During this time the cows were watered in the morning and at noon, when turned out, but not at night. After this they were watered three times a day, and on the 15th we obtained 343 pounds; 16th, 340 pounds; 17th, 347 pounds. We also feed regularly and give each cow the same quantity. I judge during the time that the hay was of the same quality. I should say that the care and attention given was the same during this time. The cows were milked clean and regularly. The hay and other feed was of about the same quality the entire time.

The temperature of the weather as recorded by J. N. Barr, in Independence, was as follows:

DATE.	Temp.	
	7 A.M.	7 P.M.
January 10 ...	10	30
January 11 ...	27	26
January 12 ...	10*	16
January 13 ...	26*	8*
January 14 ...	2	4
January 15 ...	0	0
January 16 ...	4*	4*
January 17 ...	16*	15*

* Indicates below zero.

The probable conclusion, therefore, is that the better system of watering the cows three times a day added to the quantity of their milk. Prof. Sanborn says: "What cows will naturally drink per day by one watering, will be exceeded by two waterings by about 10 to 12 per cent, and is followed by a slight increase of milk without loss of butter product as shown by the churn. When the water desired by the cows was cut down about 40 per cent (too much for a good test) the milk flow declined heavily, and also the amount of food eaten as well as a consequent loss of weight of the body."

It is said that the agricultural college at St. Remy made experiments to determine the effect of warming water to 66 degrees F. before giving it to the cows, and found in the case of two cows given the same amount of food an increase of one-third by warming. There is no question but what there would be an increase, but it seems almost impossible to think that it could be 33 per cent. It is not to be assumed that warming the water would operate alike on all cows. It is not to be expected that a cow giving 40 pounds per day can be increased to 53 by this system. A cow giving 12 or 16 might be increased to 18 or 21 pounds per day, possibly. Any close observer has noticed that cows will drink more when the water has not been chilled by exposure, than they will when it is very cold.—J. N. MURPHY.—*Farmer's Review*.

AN ALARMING DISEASE AFFLICTING A
NUMEROUS CLASS.

THE disease commences with a slight derangement of the stomach, but, if neglected, it in time involves the whole frame, embracing the kidneys, liver, pancreas, and in fact the entire glandular system; and the afflicted drags out a miserable existence until death gives relief from suffering. The disease is often mistaken for other complaints; but if the reader will ask himself the following questions he will be able to determine whether he himself is one of the afflicted:—Have I distress, pain, or difficulty in breathing after eating? Is there a dull, heavy feeling, attended by drowsiness? Have the eyes a yellow tinge? Does a thick sticky mucous gather about the gums and teeth in the morning, accompanied by a disagreeable taste? Is the tongue coated? Are there pains in the sides and back? Is there a fullness about the right side as if the liver were enlarging? If there costiveness? Is there vertigo or dizziness when rising suddenly from a horizontal position? Are the secretions from the kidneys scanty and highly coloured, with a deposit after standing? Does food ferment soon after eating, accompanied by flatulence or a belching of gas from the stomach? Is there frequent palpitation of the heart? These various symptoms may not be present at one time, but they torment the sufferer in turn as the dreadful disease progresses. If the case be one of long standing, there will be a dry, hacking cough, attended after a time by expectoration. In very advanced stages the skin assumes a dirty brownish appearance, and the hands and feet are covered by a cold sticky perspiration. As the liver and kidneys become more and more diseased, rheumatic pains appear, and the usual treatment proves entirely unavailing against this latter agonising disorder. The origin of this malady is indigestion or dyspepsia, and a small quantity of the proper medicine will remove the disease if taken in its incipency. It is most important that the disease should be promptly and properly treated in its first stages, when a little medicine will effect a cure, and even when it has obtained a strong hold, the correct remedy should be persevered in until every vestige of the disease is eradicated, until the appetite has returned, and the digestive organs are restored to a healthy condition. The surest and most effectual remedy for this distressing complaint is "Seigel's Curative Syrup," a vegetable preparation, sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White, Limited, 17, Farringdon-road, London, E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

Market-Place, Pocklington, York, Oct. 2, 1882.

Sir,—Being a sufferer for years with dyspepsia in all its worst forms, and after spending pounds in medicines, I was at last persuaded to try Mother Seigel's Curative Syrup, and am thankful to say have derived more benefit from it than any other medicine I ever took, and would advise any one suffering from the same complaint to give it a trial; the results they would soon find out for themselves. If you like to make any use of this testimonial you are quite at liberty to do so.—Yours respectfully,

(Signed) R. TURNER.

Seigel's Operating Pills are the best family physic that has ever been discovered. They cleanse the bowels from all irritating

THE INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA:—SATURDAY, MAY 2, 1885.

[No. 18.]

Crop and Weather Report.

[FOR THE WEEK ENDING THE 22ND APRIL 1885.]

General Remarks.—Slight rain has fallen in several districts in the Bombay Presidency and generally throughout the Punjab. In Bengal, the Central Provinces, and in the Central India and Rajpootana States, slight local showers have occurred. In Assam heavy rain continues to fall.

Prospects remain unchanged in Madras, and the harvest yield is reported to be below the average in some districts. In Mysore prospects continue unfavourable.

In Bombay and the North-Western Provinces and Oudh the *rabi* or spring harvest is approaching completion, and preparations for the *kharif* or autumn crop have begun in places. The *rabi* harvest is in active progress in the Punjab, and has been nearly completed in the Central Provinces, where threshing and winnowing are going on. In the Berars the *rabi* crops have been reaped, and preparations for the *kharif* are progressing. In the Central India and Rajpootana States, agricultural prospects are generally good.

Rain is much wanted in Bengal to facilitate agricultural operations. Sowings continue in Assam, and prospects are on the whole favourable.

Cholera and small-pox are generally prevalent.

Prices are fluctuating in the Punjab, and show a tendency to rise in Bengal. In other Provinces they remain generally stationary.

Madras.—Prospects fair, except in parts of Bellary and Anantapore.

Bombay.—Slight rain in parts of sixteen districts. Standing crops injured by floods in parts of Shikarpore; sugarcane slightly improved by rain in parts of Belgaum; preparations for *kharif* crops in progress in parts of Dharwar, Satara, and Khandesh. Scarcity of drinking-water in parts of seven talukas of Dharwar, four of Belgaum, and two of Bijapore, and of fodder in parts of three talukas of Dharwar and four of Belgaum. Cholera and small-pox in parts of eleven and fever and cattle-disease in parts of nine districts.

Bengal.—Weather very hot; slight rain fell in some districts, chiefly in the Dacca and Chittagong divisions: rain is urgently wanted. Agricultural operations are retarded for want of it in some places, though sowings of early paddy and some *bladoi* crops are going on; *boro* paddy and *dalia* are being harvested. Prices of food-grains show a slight tendency to rise. Public health on the whole good.

N.-W. Provinces and Oudh.—Harvesting nearly completed. Market well supplied, and prices generally steady. Cholera continues in Agra; new cases reported from Saharanpore and Aligarh, otherwise public health fair.

Punjab.—Rain in all the districts of the province, except Hissar, Delhi, and Umballa. Health good; a few cases of cholera have occurred amongst pilgrims from Hurdwar and Delhi. Outturn of crops in Lahore district poor, elsewhere prospects are on the whole good. Price fluctuating.

Central Provinces.—Weather continues uncertain, with occasional storms. Prospects are unchanged.

British Burma.—Slight small-pox and cholera here and there, otherwise public health good; health of cattle good. Slight rainfall in some districts.

Assam.—Weather hot with occasional wind. Sowing of *am* crop nearly finished; prospects good. Ploughing and sowing of *dumali* and *murali* crops progressing. Public health fair.

Mysore and Coorg.—Paddy crop in good condition. Rain much needed for coffee plants. Prospects of season and public health good.

Bejer and Hyderabad.—Weather cloudy and close, with occasional thunder and duststorms. Threshing almost completed; preparations for *kharif* progressing. General health fair, except in Shahabad taluka, where fever and ague prevail.

Central India States.—Weather clear and pleasant, though warm. *Rabi* and opium good. Health good.

Rajpootana.—Weather changeable. No further cases of cholera reported. Prices steady. Health good.

Nepal.—Weather hot and dry. Prospects indifferent, owing to want of rain.

Letters to the Editor.

SEEDLINGS FROM GRAFTS.

TO THE EDITOR.

SIR,—Allow me to make a few remarks upon a theory, which appeared in your issue of 4th April 1885, p. 159. It was there stated that "it is a well-known circumstance in the practice of grafting and budding, that, if seedlings are raised from grafted plants, they invariably turn out of a degenerate species; and the fruit they yield is of the same quality (if not worse) than the parent stock, upon which the better species was grafted."

This is a horticultural theory, which, although it is said to be derived from the practice of grafting and budding, and to be invariable, is, in my opinion, certainly not in accordance with facts. Does it imply that, each of the 400 or 500 varieties of apple (many of them very choice), which are now grown in England, came only from seeds of apple-trees which were grown on their own roots? That all the innumerable varieties of grapes, oranges, mangoes, &c., &c., now in existence, have originated from seed grown on plants with their own roots? That all the fine choice roses, now in cultivation, have been raised from seed, grown on their own root-rose-bushes? It would appear that this is one of those theories which are hastily drawn from a very limited practice. It is certain that it does not apply to the orange, nor to the mango, and it is certain also that it is anything but invariable. According to this theory, none of the many improved grafted or budded plants could have taken any part in producing the innumerable varieties now under cultivation, as it is said, that seeds taken from a graft or bud invariably produce degenerate progeny. Let any one extend his practice to raising tens of thousands of seedlings, instead of a few dozen, and give high cultivation, with other favorable conditions, he will then I think find that this theory requires reconsideration. Some persons have a notion that if they sow a few seeds, anyhow, of any good fruit, they will get equally good fruit out of the seedlings. They are disappointed to find they are probably worse than the parent, and hastily conclude that the fault lies with the seed having been obtained from a graft! It is much like taking a ticket in a 1000 ticket lottery. You may get the prize, but the chances are 999 to one that you won't. Raise 10,000 seedlings of any grafted or budded fruit, and nurse them properly, and give them every chance of healthy and vigorous growth, and you will find that the resulting phenomena are roughly divisible into three classes, more especially if the seeds have had an opportunity of being crossed. (Darwinian biologists think that no two can be exactly alike.) First, the majority of the seedlings will turn out inferior to the fruit, from which the seed was taken, with many variations—not because they may have been seeds of grafts, but because they have inherited bad qualities from their ancient wild progenitors as civilized man does now inherit bad qualities from his remote ancestors, although his immediate parents may be every thing that is good. Second, a certain number of the seedlings will be equal to the parent fruit, more or less varied. Third, the minority will be better than the parent. One of the reasons why raisers of new choice varieties of fruit, or other trees, charge so highly for them when they first bring them out, is that they have to recoup themselves for all the years spent in sowing thousands of inferior plants, the labor and time bestowed on which, until they are proved, being thrown away. The worthless ones are then dug up, and used for firewood, or other purposes. Of course no nurseryman will undertake to raise new fruit unless he has great facilities for this work, as this business does not pay; moreover, few persons ever think that the flowers of their grafts can be so easily crossed by insects with the pollen of

the original wild kinds, where these exist in the vicinity. Crossing even with the best blood will sometimes "throw back." What can be expected if bad blood be admitted?

It is probably established that the stock sometimes influences the graft, and vice versa, but that seedlings raised from grafted plants invariably turn out of a degenerate species is unbelievable, and far from a "well-known circumstance in the practice of grafting and budding."

E. BONAVIA, M.D.

Etawah, April 26, 1885.

Editorial Notes.

IN continuation of our review of Captain Parrott's report of the Hantawaddy and Pegu Districts, we note that the first results of the settlement officer's proposals are as follows:

The average incidence of revenue on paddy land per acre, together with the total land revenue without cess, are—

	Incidence	Revenue.
At present or old revenue rates...	1.80 Rs.	4,08,471
At proposed maximum rates —	1.96 „	5,03,004
At rates proposed for present application...	1.74 „	4,48,381

The net increase therefore under the rates proposed to be applied, would be Rs. 39,910 a year, or 9½ per cent.

Captain Parrott's proposal has received the approval of the Commissioner, who, however, considers it improbable that the maximum rate will ever be applied during the term of the settlement. It is thought that the higher rate is likely to be much felt by the people in certain parts of the Meynizaya circle, where the prevalent rates have been 10 and 7½ annas.

THE brick-field rate has been sanctioned at Rs. 10 instead of Rs. 25 the acre, as recommended by Captain Parrott; but the rate on tobacco lands remains at Re. 1 the acre. This is as it should be, for the only way to encourage the cultivation and other miscellaneous crops, is by levying a very low rate of assessment.

THE revenue from fruit trees has been fixed at a uniform rate of four annas the tree; but it would only apply to fruit-bearing trees or trees standing on unoccupied land, or on land not paying revenue, or on land paying the fallow rate only, and trees belonging to one person, but standing on land held by a cultivator altogether separate from the tree owner.

THE lower rates on paddy land proposed by Captain Parrott have received the sanction of the Chief Commissioner, and will be applied in all tracts except Meynizaya. The reasons given for not applying the maximum rates are, that they would cause too large an increase, coming as it would after the enhancement of 30 per cent imposed in 1879-80; and also because the price of export paddy is not now so high as it was during the last six years. The averages for those years were reckoned as not likely to fall below Rs. 70 per 100 baskets, while during the month of February 1885, Rangoon prices had gone down as low as Rs. 60 and 65, as compared with Rs. 86 at the same season in 1884.

THERE was stronger reason for not attempting the increase of rates, viz., falling prices, cheap grain in Europe, and serious disasters among rice-exporting firms, owing to the high prices paid for paddy in 1883-84. And although against these drawbacks may be cited the close proximity of rice-growing districts to the good mart of Pegu, the traversing of one side of the circle by a canal, and another by the new railway to Toungoo, the great strides made in cultivation, and the cultivated area having been much under-measured by Thugya, yet it was not considered wise to raise the demand at one stroke.

UNDER these circumstances, therefore, the revenue to be collected from 1st July 1885, has been fixed at Rs. 4,33,672, instead of Rs. 4,48,380, as proposed by Captain Parrott. This is an increase on the demand under the old rates, and a decrease of Rs. 14,708 on the settlement officer's proposal, the incidence being 6.17 per cent.

WE have noticed the thoroughly practical and interesting nature of Captain Parrott's report, and it is gratifying to find that his work has been suitably acknowledged as a fitting tribute to his labours, by the Chief Commissioner of British Burmah. Although the season's work terminates this officer's connection with the settlement portion of the duties upon which he has been engaged for the past six years, yet his connection with the province he has helped to settle will continue in the capacity of a Deputy Commissioner of one of the districts. We entirely echo the encomiums passed upon Captain Parrott's labours, and repeat that the people, as well as the revenues of the province will, for many years to come, derive benefit from the excellent work done by him.

WE have before us the result of the labours of Mr. E. C. Ozanne, who was appointed to the newly-created post of Director of Agriculture in the Bombay Presidency, which he joined in July 1883 after his return from furlough, which he would seem to have devoted more to duty than to recreation.

THERE is reason to believe that Mr. Ozanne spent the greater portion of his furlough in study at the Royal Agricultural College, Cirencester, to qualify him in a greater measure for the post he was intended to fill. When we take into consideration the scope of the operations contemplated by the new department, there can be little doubt that the knowledge which Mr. Ozanne brought after a sojourn in the Cirencester College was absolutely necessary to enable him to discharge efficiently the responsible duties required of him as Director of Agriculture; and being armed as he is with diplomas not only of the Cirencester Institute, but of the Royal Agricultural Society of England, it will be admitted on all hands that he is duly qualified for his onerous appointment, and therefore entitled to speak with an unusual degree of authority on all matters affecting agriculture and kindred subjects. It is therefore with no small degree of interest that we proceed to review his report for 1883-84—being the first of its kind.

WE find that Mr. Ozanne spent much of his time in visiting the various farms and agricultural schools scattered about India, with the object, we presume, of making himself acquainted with their working. It may be mentioned *en passant* that unless the Director of Agriculture, of any province whatever, spends some of his time in visiting model institutions, making enquiries and supervising experiments on the spot, there can be very little hope of any practical results being obtained, and we are glad to find that Mr. Ozanne has seen the necessity of this.

THE system of collection of revenue and rental in precarious tracts has, we find, not been taken up; but under the head of 'measures of protection,' including fodder reserves and arboriculture, extension of communications and irrigation, Mr. Ozanne makes some practical observations on the uses of the pod of the *babul* (*acacia arabica*) for tanning purposes. It will be interesting to learn whether this product is likely in time to become an article of export. The subject of arboriculture is confined to the discussion of the value of the *rab* as a manure. We expected something more than that under this head.

IT is disappointing to find that the authority of the Director should be so hampered by red-tapeism as to place agricultural farms under the orders of the Collector of a district. This is a division of authority which we do not approve. The sketch of operations on the several farms during the year, shows that at Bhadgaon, the work and result were decidedly unsatisfactory, for which reasons are given. The manufacture of cheese is an important element in this farm; and if the superintendent, who is bringing out fresh information on the subject from England, can apply his knowledge practically, satisfactory results may be looked for.

THE working of the Hyderabad farm is more hopeful. The experiments with common pulse seeds were not, however,

successful, while those with nankin cotton were. Steam ploughs have been found to be used successfully by the natives, who prefer them to ordinary ploughs. The financial results of the farm show a deficit of Rs. 783, which is exclusive of the pay of the Superintendent and clerical establishment. An experiment with ensilage proved a failure, as the excavation was made in land containing 53 per cent of sand.

.

THE Botanical Gardens, Ghunneskhind, Poona, did some good work. It was found that burial destroys the reproductive power of prickly pear.

.

MR. OZANNE states that it has been decided by Government that model farming will not be attempted, and that the action of Government will be confined to experiment; but undue stress will not be laid on financial results. This is quite correct; as, if an experiment is undertaken with the financial results only in view, much cannot be expected. The experiments with cotton were not successful, although prizes were offered for each of the four cotton talukas of Dharwar. Nor did the introduction of jute afford encouraging results.

.

UNDER indigeneous experiments, tobacco was tried. Its cultivation was all that could be desired, but the curing was an utter failure, although every attempt was made to carry out this process successfully.

.

THE question of ensilage has assumed much importance; for we learn from England that the Government have taken up the subject in right good earnest. Before the mail left London, it was arranged to appoint a Royal Commission for the purpose of conducting a thorough enquiry into the matter. The Commission was expected to commence its labours immediately after Easter.

.

It is satisfactory to note that among those who have consented to take part in the Commission, there are three Peers of the realm, six members of Parliament, and several leading agriculturists. There is thus much hope of satisfactory results being obtained from the enquiry, and we shall await with interest the publication of their report.

.

THE last number to hand of the Journal of the Agricultural Society of India, Vol. VII., contains some interesting papers. We notice the following as deserving attention:—"Notes on Vanilla," by T. Langlois, Esq., is a practical guide for the cultivation and preparation of Vanilla for commercial purposes. Mr. Langlois has evidently had much experience with this plant.

The Report on silos in Mysore, contributed by Sir Herbert Macpherson, proves two facts, viz. (1) that the experiment in ensilage was a success, and (2) that small silos in greater number are preferable to a single large one. The latter point should be borne in mind by those who undertake the construction of silos.

The Report of the Committee, appointed by the Bengal Government, as to the best fibre-cleaning machine, will be read with interest. We have already, in previous numbers, noticed this report, and only refer to it here incidentally.

Captain Frederick Pogson's paper on Indian wheat contains some useful hints. His suggestion for the introduction of maize of good quality in place of bajra, marwa, kuangnee, &c. is a good one, only it would be rather difficult to persuade ryots and zemindars to adopt the suggestion.

.

THE death of Sir Lawrence Peel, one time President of the Society, forms the subject of a paper in this volume. It is a graceful tribute to the memory of an excellent President, and a large-hearted, generous man.

.

CAPTAIN PASSON has floundered somewhat, we think, in his attempt to show that the existence of cattle salt—or more properly black salt—was unknown to the members of the Board of

Revenue. In fact, he appears to be quite 'at sea' as to its composition and manufacture. Baboo Protub Chundra Ghose, the Vice-President of the Society, correctly describes the article, the name of which, Captain Passon says, was not fit to be uttered in the presence of "ears polite."

.

MR. COGSWELL's paper on the jute fibre-preparing machines, will be found of value by jute cultivators and manufacturers.

The treatment of "wither blight" on tea plants will be read with interest by our tea planters, it concerns them very deeply. The paper is a practical one, and needs no comment.

From Mons. Dumaine's paper it would appear that the lac insect (*Coccus Lacca*) can be propagated *ad lib* by trans-plantation. As the lac industry is of some commercial importance, the hint is worth promulgating.

Mons. Dumaine's method of rearing the tussar silkworm will be read with much interest. It is only by such practical experiments that satisfactory results can be obtained.

.

THERE can be little doubt that the cultivation of the vine in Cashmere has made rapid progress, judging from Dewan Lakhpat Rai's paper on the subject. There are no less than 352,525 plants under cultivation. There are 18 varieties of the grape, of which 2 are used in manufacturing white wines, 6 in the manufacture of red wines, and 10 are table grapes. Two Frenchmen are employed upon this important industry—one to supervise the gardens, and the other in charge of the wine department. With vine cultivation on such a large scale, we ought to hear of Cashmere wines in the market.

.

THE results of the experiments conducted by General Wilkinson in feeding milch cows on ensilage, are very important indeed. If any doubt existed before as to the superiority of ensilage over grass, they must inevitably be dispelled by these results. It would be almost too much for one's credulity—were the facts not vouched for—to be told that two cows when fed on ensilage for 28 days gave an increase of as many seers of milk, and two similarly fed on grass, decreased by 80 seers of milk in 28 days!

.

WATER is now being purified at Philadelphia by mixing air with it under pressure. The pressure assists the absorption of oxygen by the water and its consequent purification. A Fairmount turbine has been transformed into an air-pump, which forces 20 per cent of free air into the water main, or, in other words, sufficient to surcharge the water. Analysis shows that the quantity of free oxygen in the aerated water is 17 per cent greater than before aeration, while the quantity of carbonic acid is 53 per cent greater, and the total of dissolved gases 16 per cent greater. The percentage of free ammonia is diminished to one-fifth of its former amount. The results are held to show that aeration is quite practicable as a successful means of reducing the percentage of organic impurities in water.

.

THE return lately published of the areas under tea and coffee cultivation in India for the year 1883, discloses some interesting facts. A comparison between the figures in the year 1875-76, and those in the year under notice, shows that in the former year in Assam and Cachar, 87,307 acres yielded 20,028,890 lbs. of tea, and in 1883, 18,4953 acres yielded 52,171,20 lbs. In Bengal 26,378 acres produced 4,941,226 lbs., and in 1883, 49,753 acres produced 10,703,139 lbs., while in the North-West Provinces, 4,263 acres gave 631,182 lbs. as against 7,819 acres giving 1,302,147 lbs. In the Punjab 4,946 acres produced 679,949 lbs. against 7,964 acres yielding 1,300,010 lbs. In Madras, 2,392 acres produced 220,070 lbs. as compared with 5,423 acres yielding 529,490 lbs.

.

Two small plantations in Burmah are mentioned—one of 150 acres at Akyab, and another of nine acres in Toghoo, but their produce is said to be very trifling. So that during the nine last years, the acreage under tea increased by nearly 100 per cent, and the whole outturn by nearly 149 per cent. By

taking the separate districts, we find that in Assam there were 49,091 acres in Cachar, 40,532 in Sibsagar, 36,873 in Lakhimpore, 28,083 in Sylhet, 16,601 in Durrung, 10,786 in Nowgong and 6,220 in Kamroop. In Bengal of course, nearly three-fourths of the tea-producing areas are in the Darjeeling district, which had 33,817 acres, whilst Julpigoori had 9,220, Chittagong 2,909, Lohardugga 2,752, and Hazaribagh 1,023. In the North-West Provinces, there were 4,775 acres in the Doon, and 3,043 acres in Kumaon and Garhwal.

In the Punjab there were 7,964 acres in Kangra, and only one small plantation elsewhere; while in Madras there were 4,772 acres in the Nilgiris, and 580 acres in Travancore. In regard to coffee, the whole area under mature plants in 1883 was 185,839 acres, and the entire yield about 30½ million pounds; which is very much below the mark as compared with previous years, of which, however, the returns are said to be imperfect. Mysore has the largest area under coffee, amounting to 82,108 acres; Madras has 53,917 acres; Coorg has 41,600 acres; Travancore 6,268 acres; Cochin 1,938 acres, and Bengal only 8 acres.

A CONTEMPORARY says, in a recent article we wrote, "Salt shows a steady growth in spite of a serious falling off in the Madras Presidency. This last merits more explanation than is given to it; a decrease of ten lakhs of rupees in the revenue from salt in Madras is more worthy of explanation than the many general trade matters which have had pages of this statement devoted to them." An authority on the subject tells us that the reason of the decrease is very simple. For many years past it has been the practice in Madras to give wholesale purchasers of salt six months' credit on deposit of Government paper or other easily realisable safe security. Until quite recently no more than about 25 per cent. of the whole quantity of salt passed out of the works was removed under this system, but within the last two or three years there has been a great increase in these credit sales, and more than half of the salt is now cleared on these terms. The only reasons that are given for the development of the system are that it took the up-country dealers years to find out its advantages to them, and that of late the large dealers in Madras have established agencies at such important (salt) centres as Negapatam and Tuticorin. The result, we are told, is that the sum due to Government on account of these credit sales is now some ten lakhs more than it was a year or so ago, and on March 31, stood at about 37 lakhs against 27½ lakhs on March 31, 1884. There has, therefore, been a postponement of the collection of revenue, not a loss of revenue. It may be objected that Government loses interest on the money thus due to it. But if the money was paid in to-day it would not be used to pay off debt, but to raise the cash balances which earn no interest. But even if there is a loss of interest the officials think that the community gains more than Government loses by a system which stimulates and encourages the salt trade.

THE *Mechanical World* notices a new substance, called *vulcanized fibre*, which is designed to replace india rubber and leather for mechanical purposes. It is said that among the new materials that have of late years been introduced for such purposes, none appear to have stood the most crucial test of time so well as the vulcanized fibre now under notice. Although, comparatively speaking, a new substance, there are two reasons which account for its great and increasing popularity, and these are its almost universal applicability to all mechanical requirements, and its lowness of cost. The fibre is prepared by treating vegetable fibre, previously reduced to a finely-divided state, with certain active and powerful chemical agents, by which process the properties of the vegetable fibre are entirely changed. From the fibre so treated, two kinds of the vulcanized fibre are made, these being the hard fibre, which is well adapted to replace the softer metals, and the flexible fibre, which greatly resembles leather in its pliability. In the course of its preparation from the vegetable fibre it is made into two forms, sheets and tubes or cylinders; and from these two all other shapes and forms are produced. It is generally

prepared in three colors, *viz.*, a very bright grey, Indian red, and black, and the latter colored fibre so closely resembles ebony that it can only with difficulty be distinguished from it, while the Indian red has so much the appearance and color of leather, that sheets of fibre of this color will be readily mistaken for the best sole leather. It is said that the hard vulcanized fibre has a specific gravity of about 1.3, and possesses remarkable anti-friction properties which render it very serviceable for bearings or journals of machinery, and for slides, gibs, bushings, etc. It is said to be an excellent non-conductor, alike of heat or electricity, and as it stands a very high degree of heat without injury, it is especially applicable, and is most extensively used for electrical insulation. It is described as being very tough and hard, and in its texture and general properties bears a strong resemblance to horn, with the exception of being homogeneous throughout, and having no stratification or cleavage.

It works well in the lathe; can be cut with a sharp, strong screw thread; takes a fine polish, and can be readily drilled, riveted, sawn or stamped. A further advantage claimed for it being that it is not affected by oils of any description; and when used for small high-speed journals, it greatly outlasts brass or Babbitt metal, and requires only about one-half the usual lubrication. In its flexible form the fibre, it is said possesses all the foregoing advantages as regards toughness and strength, and only differs from the hard class in its pliability, which approaches that of rubber or leather, but unlike either of these, it is unaffected by oils, fat, heat, &c., and does not become soft and limp when exposed to their action. Further, that this class of the fibre is chiefly used for carriage axle washers, plumbers' washers, gaskets for water packings, oil box covers, &c., and when it is stated that either class of the fibre is perfectly insoluble in hot or cold water, oil, naphtha, petroleum, or alcohol, and is but slightly affected by most of the acids, it will readily be seen to what a wide range of purposes this material could be applied. When used as a facing medium with that type of friction gearing, consisting of a wheel having a non-metallic face, bearing hard against a driven wheel with a metallic face, the fibre has always given unqualified satisfaction. With such advantages it will be readily understood what a valuable commodity this new substance is likely to prove. In India especially, where India-rubber and leather lose their usefulness with very little hard work, the vulcanized fibre would be found of immense benefit, if the qualities attributed to it can be accepted as correct. It would, we think, be worth while trying a few experiments with it out here.

THE report on the prospects of the wheat crop in the North-Western Provinces and Oudh for the month of March is as follows:—"Wheat area of the United Provinces for March is 5,284,404 acres, which is greater than the area reported for February by 18,085 acres, and greater than the normal area by 318,721 acres. Taking normal area at 100, the area now under wheat in the United Provinces is 106, area under white wheat is 1,213,980 acres, area under red wheat is 2,010,239 acres, area under mixed red and white wheat is 2,060,185 acres. The month of March has been favourable with bright weather and westerly winds, and the prospects of the crops have decidedly improved. Taking 100 to represent full average, the condition of the crop is as follows:—56,264 acres stand at 100; 641,323 acres at 90; 2,803,881 acres at 84; 1,740,461 acres at 75; 42,464 acres at 66. The gross outturn of one full average crop on the area, as now ascertained, would be 2,500,000 tons. The present estimate of the season's crop is 2,040,000 tons, or 90,000 tons in excess of the February estimate. Taking 100 to denote the gross outturn of a full average crop, this season's crop stands according to the present estimate at 82."

A later report gives the following additional information:—"Estimated gross outturn of the three sorts of wheat in the United Provinces is as follows—white wheat 491,884 tons, red wheat 745,185 tons, mixed red and white wheat 804,480 tons. Estimated total stock of wheat in the United Provinces on 1st April 60,000 tons."

Miscellaneous Items.

18,881 bales of cotton, weighing 68,909 maunds, 33 seers, were imported into Kurrachee by rail during the month of March 1885.

It is notified that the charge of the Inam department has been entrusted to the acting Director of Revenue Settlement and Agriculture.

This estimate, amounting to Rs. 18,370, for completing the upper storey of the Agricultural College at Saidapet, has been sanctioned by Government.

EXTENSIVE and valuable phosphate deposits are said to exist in a singular natural cavity in Alachua county, Florida. About 87 per cent of the rock is pure phosphate.

The weather keeps very seasonable, i.e., hot winds blowing as if from a furnace, and a still hotter sun; the nights and mornings pleasant, and the public health very fair for the time of year.

THE net amount of Indian sea and land customs revenue, exclusive of the salt revenue, for the official year 1884-85, was Rs. 98,14,000 as compared with Rs. 1,13,98,000, in the previous year.

THE last *Calcutta Gazette* contains the lists of gentlemen who may be called upon to sit as Special or Common jurors during 1885-86. In the first list there are 200 names, and in the second 1,939 names.

THERE was a heavy fall of rain at Coonoor last week accompanied with hail. Several heavy showers have also fallen in Wynaut. On Friday last, about noon, two inches of rain was gauged at Furaklore.

THE Masters of the vessels now in port (Langoon) are so greatly vexed by the desertion of their crews, that some of them have given the Police *carte blanche* to arrest any of their men who may be found ashore, and have promised to defray the costs of arrests.

A new barrel has been patented by Mr. George F. Knapp, of St. Louis, Mo. This invention provides means whereby the centre of the barrel may be securely held, while either end is adopted to be opened to examine the contents, and so the hoops may be locked securely or readily unlocked.

ON the occasion of the appointment of Mr. H. L. Wright to act as Collector of Customs during the absence of Mr. G. F. M. Grant, Mr. W. J. Long acts as First Assistant, Mr. J. J. Langner as Second Assistant, and Mr. W. J. Almon as Third Assistant Collector.

A MARINE Court of Enquiry, which was recently convened at Akyab, to enquire into the circumstances connected with the loss, on the Oyster Reef, of the Italian barque *Irreputabile* on the 9th of last month, has, we learn, found the master guilty of culpable neglect of ordinary precautions.

Those troubled with mosquitoes will find a remedy which has been discovered in Sydney. It is asserted that if a tablespoonful of carbolic acid is put on a plate, and a piece of iron is heated and placed in the acid, dense white fumes will arise which will promptly drive all flies and mosquitoes out the room.

THE planters in the Kangra Valley are organizing an Infantry Volunteer Corps to be called the Kangra Rangers. Great enthusiasm prevails. The corps will practically be a body of Mounted Infantry, as each member will have to ride a long distance to parade, and will carry his carbine in cavalry fashion.

WE learn that the Munda market in the village of Ushtoo, Satara Collectorate, tumbled down on the evening of the 17th April, and that fifteen men were buried under the debris. Assistance being rendered and the bodies removed, it was found that two men were killed, while the thirteen others were more or less severely injured.

MR. T. MANICKUM NAICKER, to whom the silver medal was awarded by the Madras Agricultural Society last February for indigo, and Mr. T. Moonosawmy Naicker, to whom the silver medal for tobacco was awarded, at the late show, having applied for cash in place of medals, their requests have been complied with by the Society.

THE value of cattle lost by disease in the Madras Presidency during the year 1883-84 is estimated at Rs. 2,68,080. This figure is arrived at by taking Rs. 25 as the average value per head for sheep, cattle and buffalo, and Rs. 2-12 per head of goat, and deducting one-fifth from the total on account of young and under-sized animals. The two most destructive diseases were anthrax and rinderpest.

THE veterinary hospital in connection with the Madras Agricultural College at Saidapet is doing useful work. The Director of Agriculture reports that some of the students have turned out very good practical men. The cases admitted to the hospital for treatment, and the medicines supplied to the public, both show a large increase in 1884 over the previous year.

THE transfer of the Economic Museum to the Government of India is likely to be postponed till next year. Mr. Buck just now has his hands full of work in connection with the preparations for the Indian and Colonial Exhibition, to be held in London next year; and, besides, the time is not favourable to the Government of India undertaking any financial obligations that can be conveniently shelved for the present.

A SECTIONAL non-conductive covering for tubes has been patented by Mr. William M. Suhr, of New York city. It is formed of two semi-cylinders of plaster of Paris, asbestos, and sawdust, covered on the outside with a layer of felt, which in turn is covered by a layer of thick paper, the covering being formed in sections and delivered dry and hardened ready for application, so a large quantity of pipe can easily be covered in a short time.

AROWAN Factory, in Chupra, we are told by a contemporary, has again been the scene of an outrage on the person and property of Mr. MacGregor. Some nights ago he awoke by hearing a movement in his room, and was soon in hot pursuit of the thief, who, finding himself on the point of being captured, flung his *puggree* in Mr. MacGregor's face, and then hitting him on the head with a *lathie* got off, but dropped a watch and chain which he had secured in the bed-room.

A VERY important judgment as to the rights of landowners on the sea-shore was recently delivered in Penang by his Honor the Chief Justice in the suit of Mr. J. L. Wemyss, a machinist, iron founder and boiler maker, who rented land on the seashore under a lease from the owners, and claimed damages for loss of access to the sea through the Government reclamation of the shore outside of his premises. The Chief Justice held that a private right had been invaded, and that he was entitled to damages.

CHRYSAANTHEMUMS in Japan are trained into numerous quaint shapes, like the old English yew-trees, in the forms of peacocks, &c. In Tokio there are gardens filled with life-sized figures made entirely of the flowers and leaves, the faces being masks, and these chrysanthemum figures accurately represent Court ladies, warriors, children, and animals, one of the favourite characters being a young lady with a fox's tail peeping from under her dress, and a mask which by the touch of a string turns into Reynard's head.

WE are glad to learn that the prize of Rs. 100, offered in connection with the Agricultural Exhibition lately held at Doornroos, has been awarded to Baboo Chunder Bhushan Dutt, a higher-grade officer of the Subordinate Establishment of the Bengal Public Works Department, attached to Eastern Soane Division, for his essay on Irrigation. Baboo Chunder Bhushan is an able and intelligent young officer, and his essay on Irrigation is but an earnest of the work that the public may expect from him. We hope his future will realise the promise of his past career.

CORK bricks have recently been introduced in some parts of Europe. The material used is a mixture of cork, silt, and lime. It is stated to be a very durable material, guaranteed not to rot. It has the advantage of keeping out heat and cold. It is light in weight and easily applied. An interior wall might be made of it where an ordinary brick wall would be too heavy, whilst it would be equally durable and substantial. It is nailed up to laths as a covering under roof, or for ceilings, for wall linings, and for under-floors, as it is said to be an admirable preventive of damp, and a sound preventive also.

THE Savannah Spinning and Weaving Mills, Pondicherry, under the able and successful management of Monsieur Gustave Cornet, the resident partner, are being greatly extended. For many months past large quantities of new and improved machinery have arrived by each French mail steamer, the *Tigre* on her last trip bringing several hundred tons. We notice that a piece of the public park has lately been added to the premises, which, nevertheless, have still a crowded appearance. The Savannah Mills are, we believe, not only the oldest, but also the largest Spinning and Weaving Mills in Southern India.

LAST year we heard a great deal about experiments that were being made by Government in the making of paper stock out of *kaini* grass. If we remember rightly the experiments were conducted at Maoobin, and samples of the outcome were sent to Europe for valuation: we should now like to know the result. It is one that should be made known, for, if successful, it might induce some persons, with spare capital, to make a venture in paper-making; and, if not successful, it will be valuable as showing the reason of failure and the chances of the undertaking. Every effort, successful or otherwise, made by Government to establish a new industry or improve an existing one, should be widely published. Information of this nature is always worth something.

It appears that the Municipality can no longer give Red Hills water as freely as they have been giving it hitherto. The breach at the Red Hills was closed by a temporary ring-bund, and it was not advisable to allow the water in the lake to rise to a height sufficient to endanger this ring-bund, so the water has been kept down to a safe level, and Madras has, hitherto, had an ample supply. This state of things is now over, and, with the hot weather the water is falling below the level at which the municipal pipes will supply a sufficient head in the delivery channel. It is calculated that in about twelve days more it will be necessary to begin pumping, either at Koratoor or Red Hills, and this pumping will cost nearly Rs. 3,000 per mensem, so the supply of water will be restricted to domestic purposes. There is plenty of water. The only thing is, that it costs money to pump it into the delivery channel.

The report for March 1885, on the prospects of the wheat crop in the Punjab, is as follows. Complete statistics of the area under wheat are, however, not yet available, and some of the figures are still open to correction :—"The area under wheat in the Delhi, Gurgaon, Hissar, Ferozepur, Rohtak, Simla, Jullundur, Hoshiapur, Kangra, Amritsar, Sialkot, Lahore, Gujranwala, Jhelum, Gujrat, Shahpur, Multan, Jhang, Muzaffargarh, Dera Ismail Khan, Dera Ghazi Khan, Bannu, and Kohat districts is shown at 5,325,000 acres this year, as against 5,250,000 acres last year. In the remaining districts, Karnal, Umballa, Ludhiana, Gurdaspur, Rawalpindi, Montgomery, Hazara, and Peshawar, the estimates already received give 2,033,000 acres this year, as against 2,050,000 acres last year, but accurate statistics have yet to be received for the latter. In parts of Hissar, Jullundur, Amritsar, Lahore, Gujranwala, Multan, Dera Ismail Khan, Dera Ghazi Khan, and Bannu, the character of yield is described as below average. In the rest yield is either average or above; a full average may be estimated for the province as a whole. Further details will be telegraphed on receipt of complete and accurate statistics."

The report for March 1885 on the prospects of the wheat crop in the Central Provinces is as follows :—"Prospects remain unchanged, except that in the northern districts the injury from rust has proved larger than was anticipated. Total approximate area for the provinces is 3,700,000 acres against a normal of 3,900,000 acres. Of these Saugor and Damoh contain 700,000 acres, the Nerbudda Valley 1,200,000 acres, the Nagpur country, including the Seoni district, 700,000 acres, and Chhattisgarh 450,000 acres. The total outturn, as roughly estimated, is 22,900,000 maunds against a normal of 22,500,000 maunds. The exports fell off during March, in which month it amounted to rather over 400,000 maunds, but it shows signs of recovery, and in the first week of April reached 150,000 maunds. No information respecting stocks is available."

The report for March 1885 on the prospects of the wheat crop in the Central Provinces is as follows :—"Wheat harvest over, area under wheat generally about the average, including existing stocks; no information respecting stocks is available for export."

The report for March 1885 on the prospects of the wheat crop in the Central Provinces is as follows :—"Wheat harvest over, area under wheat generally about the average, including existing stocks; no information respecting stocks is available for export."

A DISEASE, known locally as *Mora Basanta*, is reported to be causing great ravages among the horned cattle in our Eastern districts. The symptoms are stated to be as follows :—"The animal attacked refuses its food; discharges of a viscid mucous matter from the mouth and nostrils follow, and are ordinarily accompanied by a skin eruption. Severe purging, with a very high temperature, are concomitants of the disease, which usually proves fatal on the third day. The people appear powerless to check the heavy mortality, and not unnaturally, look to the

State for help and counsel. Every civilised Government, save our own, has recognised its duties in this respect, and maintains a highly-paid establishment for the purpose of coping with cattle-diseases. In England, an outbreak of rinderpest engages the prompt attention of the Privy Council; energetic measures are taken to isolate the area attacked; and experts are deputed to ascertain the nature and causation of the disease, and suggest a remedy. If these precautions are deemed necessary in England, which is in the main, a manufacturing country, how much more essential would they seem to be in the case of India, where the agricultural interest is everywhere paramount, and where, broadly speaking, cattle are still the only form of wealth? And yet, what steps have been taken towards ascertaining the nature and cure of the various types of cattle-disease which yearly cause such untold distress, and (indirectly) so much crime? We recollect indeed, many years ago, a spasmodic effort in this direction, in the shape of a vernacular pamphlet issued under Government auspices, and treating of cattle-diseases and their cure. It is, however, more than probable that the treatment therein laid down was wholly empirical; and it is certain that we know as little of diseases of cattle in the East, as we do of those which affect our own kind. It is surely time that the new-fledged Agricultural Department bestirred itself to wipe away the reproach that India possesses no organization for the purpose of combating these destructive maladies.

ENSILAGE.

In an article last week on this subject, we gave some account of the origin and progress of silos in South Australia, and the manner of constructing them, together with the results obtained by experiments. It will therefore be interesting to see what measure of success has been obtained by similar experiments in different parts of the world. The importance of the question has been recognised everywhere, and we shall, therefore, we hope, be pardoned for dwelling at some length on this matter. We shall begin with Great Britain.

Mr. Kains-Jackson, in his remarks on the *Ensilage Show* at Islington last December, says :—"Ensilage has advanced in three years as much as have most other methods of farm practice in thirty years." This remark applies almost with as much force in India, for we find that printed papers, containing the results of several experiments, have been communicated to all local Governments and Administrations in view of trials being made, and silos being established all over the country. A writer in an English contemporary emphasises Mr. Kains-Jackson's remark quoted by us, observing that those who have tested the value of ensilage both for fat stock and dairy cows, can well understand the reason for this rapid advance, and there is no doubt that within a very short time silos, or ensilage stacks, will be as common on every farm in the kingdom as hay stacks. But the question to be solved is, which is the best and cheapest method of making ensilage, so as to come within the reach of every small occupier of land. It has been asserted that expensive masonry-built silos are unnecessary, and that ensilage may be made equally well, if not better, in cheaply-constructed wooden silos, or even in stacks without any silos at all. The question however, between the cheap wooden silos and stacks amounts to this, that whether or not the loss incurred by the extra waste round the sides of a stack, is not more than will pay for the erection of the wooden sides.

The writer goes on to say that when we consider that round the sides of a wooden silo there is, practically speaking, no damaged ensilage, the whole being fit for consumption, and that the wood for a silo 16 feet square and 12 feet deep costs only £7, and will at the very least last four years, he thinks there can be but little doubt that a silo is cheaper than a stack.

The foregoing remarks prove that in England at least, it is looked upon as certain that silos will, in time, take the place of the time-honored hay-stack, and that the constructing of silos need not cost large sums of money. In the earlier stages of ensilage experiments, an elaborately built silo was looked upon as indispensable, but the writer we have quoted would seem to have overcome that difficulty. Let us see what he has to

say about the method, generally adopted at home, of filling in and weighing. He says that several different systems of weighing have been tried, and that there is no doubt that green crops may be preserved in various ways. Exclusion of air by hermetically sealing the silos may be efficient, but it is far too expensive for any practical purpose. Great pressure by means of simple screw power has also been tried, but not being continuous in its action, it could not be depended upon, and must be uncertain in its results. He thinks that builders of silos cannot do better than follow in the steps of those who were the first to put into practice this method of preserving green crops—*viz.*, that a perfectly continuous and self-acting weight to follow the ensilage as it sinks is necessary. In support of this, he quotes M. Goffart, who says—"Never lose sight of the fundamental principles which ensure success in ensilage—continued pressure to expel all the air contained in the silo. It is indispensable to put on the cover, or moveable planks, of the filled silo, about 100 lb. per square foot of heavy matter, such as stones, &c. This great pressure ought to continue for several months, because the trampling down at the time of ensilage, however thoroughly carried out, is not in itself sufficient. At the time when the green fodder is put in, it is still living, and endowed with such elasticity that it re-acts strongly against the momentary pressure put upon it. It is not the same, however, after a few weeks or a few months; the fodder soon undergoes a softening which diminishes the elasticity, or, in other words, increases its compressibility to a considerable extent. It is when these physical and chemical modifications are accomplished that the heavy weights, which I have indicated as an indispensable condition to success, produce their salutary effect. They follow the fodder as it collapses, and produce that state of very high density which is so necessary to put it beyond the reach of deterioration."

The writer states that from experiments made by him on this subject of weighting the ensilage, and from knowing something of what others have done, he is firmly convinced that the system of continuous pressure, as advocated by M. Goffart and others, will ultimately prove to be not only right in principle, but the easiest and cheapest in practice.

The operation of weighting is of such importance, that we unhesitatingly recommend it to the notice of those engaged in ensilage experiments in India. There is so much truth in the statement made by this writer, that we are inclined to attribute the failures that have occurred in some cases to this point being overlooked.

As an instance of what an average sized silo would cost in England, we quote the estimate given by this gentleman:—

"For £24 I can buy from my carpenter the wood, including covering boards and planks, ready cut, for erecting a silo 20 feet long, 12 feet wide, and 12 feet deep, capable of holding 57 tons of ensilage, roof it with corrugated iron, and weight it with a press supplied by the Ensilage Press Company, Leicester, which gives a continuous weight, and is so simple in its arrangements that ordinary farm labourers can put it on and take it off in fifteen minutes. Allowing 30 per cent for interest and depreciation on the perishable part, and 10 per cent on the remainder, the cost for the silo and weighting per ton of ensilage per year is only 1s. 4d., not a very ruinous outlay even in these depressed times. Probably my estimate for the wood will be found to be high rather than otherwise, for I am told that wood is dearer in my neighbourhood than in most other places, and in many instances, I think the cost might be reduced by farmers using some of the wood found on the farm without having to go to the carpenters for it."

With these facts before us, we are of opinion that a silo of similar dimensions would cost far less in India, where labour and material are much cheaper.

SEEDLINGS FROM GRAFTS.

UNDER the head of "Letters to the Editor," we publish a communication from the pen of Dr. Bonavia, on the subject of seedlings from grafts. Coming from such a high authority, the letter commands our best attention; but we would say a few words relative to the conclusions arrived at, and the theory

formulated by such a distinguished botanist, who is at the same time an experienced horticulturist and agriculturist.

Our statement regarding the quality of seedlings raised from grafted plants was made from the knowledge gained by seven years' experience of this practice. It was found that in almost every case where seedlings were raised from grafts, they turned out of a degenerate species. We are quite in accord with Dr. Bonavia when he asks whether the hundreds of varieties of apples, grapes, oranges, mangoes, &c., among fruits, and the numerous varieties of our beautiful roses and other flowers, were all raised from seeds taken from plants on their own roots? It is true that these numberless varieties may have been raised from seed; but we shall, we think, not be far from the truth in saying that they were not all raised by seeds taken from grafts.

The system of hybridization has been carried to such an extent, and has reached such perfection, that raisers of plants at home and on the continent very seldom resort to any other mode of producing new and improved species. In nearly every class of plants, hybridizing plays an important part. It is only by resorting to this practice that we can hope to improve upon existing varieties. The causes which lead us to this conclusion are obvious. Take, for instance, our roses as an example. When a grower and raiser wishes to multiply varieties, or to bring out an altogether new kind, which he thinks he would be able to do by uniting the growth, health, constitution, and size and shape of a particular rose, with the colour of another, he hybridizes them, one with the other. In the same way with fruit, he selects an apple which has a good constitution and size, with other qualities that make up a desirable variety, but which lacks the delicate flavour necessary to render it a choice and popular fruit for the table. He therefore selects another, which possesses the latter, but not the former, qualities, and accordingly proceeds to hybridize them. The result will be, perhaps, out of many seedlings, a cross between the two, partaking of the qualities of both. We do not, however, think that the raiser would, for the purpose of producing a new variety, graft the superior on to the inferior, and expect to get an improved species from the seedling got from the graft.

It has been found in many cases that seeds taken from grafted plants do not contain that *vitality* and germinating power found in seeds from plants on their own roots. Again, it frequently happens that grafts do not seed, and when they do, the seeds are found to be imperfect, and fail to germinate. It is a well known fact, and one which we have often verified, that the orange and pomelo, if raised from seeds obtained from grafted or budded plants, give most unsatisfactory results. We have observed the same phenomena in the case of many other varieties of fruits, *e.g.*, peaches, plums, mangoes, &c. Were it otherwise, the native fruit-growers, who know the value of grafts, would propagate their fruit-trees from seeds, which would not only be an easier method, but simpler, and yield a larger return.

Nurserymen, in Delhi, Agra, Saharnpore, Lucknow and other places, invariably raise the superior varieties of fruit trees for sale by grafting and budding, and the inferior kinds from seeds for stocks. We have ourselves had a good deal of experience in this respect, and we invariably found that seedlings raised from grafts were of a very inferior quality—if not positively worse than the stock upon which the graft was made.

We have in this paper endeavoured to show what our own experience has been in this respect, and the conclusions arrived at from observations; but the superior knowledge, and more extensive experience of Dr. Bonavia give him an undoubted right to speak with authority on this subject. We are pleased to find that a comparatively unimportant remark of ours has elicited such an able paper, and as the subject, if thoroughly investigated, promises to become an important one, we hope our other subscribers and contributors will favour us with their views, not only on this, but other cognate subjects. We shall be very glad to open our pages to the discussion of matters relating to agriculture and the allied sciences; and if we can succeed in promoting a healthy discussion in the pages of the *Indian Agriculturist*, we shall not have laboured in vain.

arranged in piles sheltered from rain, but so as to allow the air to play freely through them to dry: after two years or so oakwood loses 20 per cent of water,—a sleeper weighing originally 81 kilogrammes will then be no more than 65 kilogrammes. The process begins by sleepers laid on little waggons being introduced into a hot-air stove in which the highest temperature is 75 degrees, the middle 60 degrees, and the lowest heat 40 degrees. After two days, the weight of each sleeper is reduced by 1 kilogramme and a little more, rarely 2 kilogrammes. The waggons are next removed to the injection cylinders, which can hold about 180 sleepers. These being hermetically closed, a vacuum of about 65 degrees is made by the air-pumps, and creosote admitted from a reservoir open to the atmosphere, and kept at a temperature of 70 to 75 degrees by means of steam. When the cylinder is full of the liquid to be injected into the wood, communication with the reservoir is cut off, and steam to the pressure of 5 kilogrammes blown in. Five operations can be performed in a day in each cylinder, the time for each operation being about two hours.

Square oak sleepers from France, Galicia, and Russian Poland are used. When the oak contains little sap, it absorbs about 5 kilogrammes the sleeper; but Polish oak, which is a little soft, takes a little more in. This preparation costs 1 franc a sleeper. Since 1877, the railway company have mostly eschewed the more tender woods, as sleepers abounding in sap absorbed 17 kilogrammes of creosote. It is essential that the sleepers be thoroughly dried, and that they immediately pass from the drying stove to the injecting cylinder, as only in such circumstances can the liquid enter the wood vessels of the most refractory oak. The drying in the atmosphere should not be too long prolonged; and the use of the stove appears to remove the last traces of moisture. When too many logs are placed in the cylinder, the creosoting becomes unequal. The work has been done more satisfactorily by the company on its own account than when it was formerly given out to contractors.

In view of an increased use of various woods, more timber-preserving experiments on different varieties appear called for,—especially in relation to fences, wooden houses, and the like. In respect of freedom from lightning-stroke to which wire fences are so liable, creosoted wood fences claim attention from agriculturists and foresters. Messrs. Armstrong, Addison & Co. give more than one instance where cattle and horses killed by lightning were found lying close to wire fences.—*Forestry.*

ABORTION IN COWS.

MR. FREDERICK HOOD, M. R. C. V. S., Penicuik, having been asked by many farmers who had sustained losses by abortion in their herds, to give his views and experience in a plain, practical form as to the cause and prevention of this complaint, favours us with an interesting paper, the second portion of which we are obliged to hold over for a week.

Dealing with the history of the ailment, Mr. Hood says:—The continuance and alarming increase of this strange and somewhat disastrous disorder among the milking stock of this country, has excited the intelligent attention of veterinarians and stockholders to a degree somewhat more lively than heretofore, and in a manner more calculated to afford something of a practical and logical solution of its many mysteries.

The importance attaching to a correct understanding of this condition cannot possibly be overrated, because, taking all other incidental diseases and losses amongst milk stock together, more loss, directly and indirectly, results from this one cause. The essential value belonging to the animal, namely, her milk, is more or less reduced, if not altogether stopped for the time being. The fattening and disposing and replacing of these unprofitable animals, the loss of the calf, together with the extreme difficulty in ridding the byres of the disorder during a period of four or five years after the disorder commences, are quite sufficient to demand an energetic and thoughtful study on the part of those whose duty it is more directly to contribute such.

The history of this disorder is contemporary with the history of civilisation. With the domestication of the cow, it has without cessation continued to exist. Among the ancient Greeks it was familiar, and one strange feature in its early history, as recorded by one of their most famous poets—a feature which I would especially draw attention to here, as exemplifying what is largely the case at the present day—namely, it occurred to a much more serious extent, the nearer we got to large centres of population. This, as I have already pointed out, and as I shall show further on, is largely the case in this country, and in others at the present moment. We must give due importance to the observations of this intelligent Greek. At the time of the Roman conquest of Britain it existed as an almost universal blight, and continued without interruption for several successive years, both cattle and sheep suffering. On the Continent it is thoroughly well-known in certain provinces, causing all but total destruction of the native stock. In our own country it has existed with greater or less severity as far back as history itself, and causes innumerable and curious were assigned for its origin—the evil influence of sun, moon, and stars—witchcraft—evil disposition on the part of departed souls, each having its believers and each having its own enchantment or charm as a protective influence against infection.

ITS AREA AND DISTRIBUTION.

Wherever the cow is bred, born, and reared in a state of domestication for the special purpose of giving milk, there exists

the disorder. Over the length and breadth of the European Continent, India, New Zealand, Australia, the American States, Great Britain and Ireland, it exists in that form, apparently epidemic, besides the incidental form due to known causes.

In those extensive tracts of natural pasture in America known as cattle ranches it does not exist nearly to the same extent—indeed, the losses from this cause among the stock pasturing on these pastures, and which are fairly looked after, is an exceedingly small percentage. With more or less accuracy this percentage can be calculated by the simple process of counting; given a certain number of cows, with their proportion of bulls, re-counting every year shows the additional in rease, which can be easily compared with what it should be. Its existence, then, is almost universal, no country where the cow is under domestication being exempt.

PRE-DISPOSING CAUSES.

We have now come to a practical division of our subject, and for purposes of elucidation, and exhausting its consideration as much as possible, I propose to sub-divide its consideration into individual predisposing causes or sub-divisions.

BRED.

Of late much importance has been attached to breed as a pre-disposing influence to many incidental diseases among cattle; rightly or wrongly as this may apply to diseases distinct as disease, no incontrovertible rule can be sustained connecting abortion with breed; and it is by an entirely false rule of application to maintain and argue distinct relationship between the two. Now, this is a fact important to remember, because many farmers and dairymen have been induced to abandon one breed highly profitable as milkers for another breed of inferior quality, on the assumption that former losses from abortion would not be repeated with this change. Breed of itself has nothing whatever to do in the matter—one breed under equal circumstances being as liable to abort as another. But breed in relation to circumstances has a great deal to do with it, and to an extent far more true than many of us are prepared to believe. For instance, climate and soil congenial to one breed is not so to another. Again, certain breeds can stand a great deal of the selective process. What I mean by that is, that for the purpose of getting in a stock of cows capable of giving large quantities, I might almost say unnatural quantities of milk, none but the heaviest milkers are kept and bred off, selection after selection is made for years of the best in the stock, until a complete transformation is made in the character of the animal from what originally was intended by nature.

The cow, intended by nature to be a strong, lively, hardy, and enduring animal with large muscular development, becomes converted by this selective process into a sensitive, delicate, unenduring creature, whose muscles have been transformed into a huge glandular system for producing milk.

Now, this abnormal development of one particular organ at the expense of the other parts of the body means weakness, means susceptibility to disease, means incapacity to perform the function of reproduction in a vigorous natural manner; the organs of reproduction which depend so much upon general vigour of the system, suffering in a manner much greater than the rest of the body; and that complex series of phenomena coincident with, and essential to, the development and maturing of the calf is faulty and incomplete; the excessive drain upon the substance of the general system to furnish material for milk, leaves little or nothing to spare for the formation of the young—a process requiring large supplies of the mother's substance.

But the evil does not stop here. This selective process, chronically weakening the reproductive organs of the mother, extends the imperfection to the young, who, in turn, extend it to theirs in an increased form, until, as has been over and over again observed, it becomes almost impossible to get certain cows in calf at all, the organs being utterly incapable of securing conception; and in many other cases when conception does take place and gone a certain length, the weight of the calf and the quantity of nutriment required is greater than the womb can supply, and hence abortion; to mature the calf further is an impossibility, and nature rids itself of what, if retained longer, would prove injurious to the mother.

SERVICE.

It is within the knowledge of most who have to do with calving cows that unproportionate bulling has a pre-disposing influence towards abortion. I will give the results of an unintentional experiment which was tried under this head, showing, in a clear and intelligible form, the influence unproportionate bulling may have. A dairy of 20 cows, of which were 10 Ayrshires of relatively small size, 5 pure shorthorns and 5 crosses, were served for some time by large, massive English bulls. The first year gave two abortions among the Ayrshires, and one could not be calved. During the second year two abortions again occurred with the Ayrshires; during the third year 4 Ayrshires aborted and 2 crosses; during the fourth year 1 shorthorn aborted with 3 Ayrshires; during the fifth and sixth years, circumstances were even more disastrous, as half of the Ayrshires could not be put in calf at all, and 3 of the remainder aborted.

Now, no other explanation could be reasonably considered other than that of disproportionate bulling, as previously abortion among the stock was rare—bulls of smaller proportions being used. Nor is it difficult, in a physiological sense, to account for such. Nature intended and has made provision for calves proportionate to the size of the mother; but when small cows are bullied with bulls as large again as themselves, the womb, or bed, is liable to collapse under the disproportionate weight, and eject the encumbrance.

Again, under this heading, we must include putting young cows too soon in calf, especially to large bulls. A query put in calf at

one year or fifteen months, as certainly too soon, particularly the smaller breeds. The bad by such a practice is considerably weakened, the energies of the whole animal are unduly taxed: indeed the bed, during the whole of the animal's life, if regularly put in calf, is pre-disposed to abort, and hence one of the many obscure causes in animals, otherwise thriving and healthy, aborting without any known cause.

Super-pureness in breed is another pre-disposing influence towards abortion. With cows, as with all other animals, over-refinement means over sensitiveness to disturbing influences; whatever is prejudicial to the general habit or constitution of the animal, and extremely little is required thus to affect pure-bred animals, tells more or less directly upon the reproductive powers of the animal.

SOIL AND CLIMATE

Have been shown to have distinct influence upon this disorder. I am alluding altogether to conditions of soil apart from marshy ground, or where wet miry pasture nearly continually exists, because, as I shall point out further on such pastures are direct exciting causes towards the disorder. What I allude to here is the question more of elevation and soil markedly reproductive of weeds, and more especially growths of the fungoid type. I will also attempt to show what influence certain artificial manures exert directly or indirectly in producing conditions favourable to abortion.

In the first place, then, districts situated at low elevations are more prolific in producing conditions favourable to abortion than high elevations; this is markedly exemplified on the Continent, where cattle grazed and housed on the low-lying plains abort to a much greater extent than animals at higher elevations under similar conditions. Again, on some of those extensive, flat, low-lying tracts of country situated in the midland and southern counties of England, abortion is of common and disastrous frequency; whereas, on the hilly tracts of southern Scotland and in the north and west Highlands, its occurrence is almost altogether accidental.

With reference to the abortive tendencies of certain weeds, especially of the cryptogamic sub-kingdom, I consider it impossible, in a short general treatise, to exhaust a matter upon which great and varied experiences exist. In a separate pamphlet, which the subject sufficiently merits, I shall endeavour to lay down those various experiences, and also experiments, carried out in a practical and scientific manner, by two or three illustrious veterinarians on the Continent. Suffice it to say here that all weeds grown upon soil regularly cultivated and manured with artificial manures are detrimental to the general physical health of the cow, and some of them, indeed many of them, directly alter the physical energies of the reproductive organs.

The part played by artificial manures in establishing influences and changes of animal conditions favourable to abortion deserves attention. In a recent publication evidences and comparisons were given of the relative tendencies induced towards disease in the human being between our own artificially-grown wheat and that of natural growth from America, Russia, and the Colonies. It was attempted to be shown that were nothing but home artificially-grown food obtainable, disease would be universally rampant. I do not for one moment ask you to believe this statement as being absolutely correct; but I would certainly point out that although this statement is not the whole truth, it contains truth, and truth which in its essence is markedly selected and expressed in our lower animals.

In feeding with artificially-reared food and artificial feeding stuffs generally, we produce an entirely new adaptability within the animal; to make use of such we induce processes and habits of digestion not in strict harmony with the laws of nature. We cause a departure from nature's originality, and invite all the forces of the animal, which hitherto had been and were intended to be equally distributed over the whole system, producing suitability and perfection in each department, to be concentrated in the processes of digestion, elaboration, and absorption of those foods. Now, no such monopoly can exist in any animal economy without involving weakness; and the function of one system is indirectly, yet often seriously, involved—namely, the reproductive. Not that its forces are destroyed, but in sympathy with the other systems which have now become altered, it naturally partakes of the same transformation; and it is an infallible rule in all animal economy that if you depart from the natural standard, as first created, you entail weakness and inadaptability to perform healthy function.

Accepting the doctrine enunciated by some of our most eminent physiologists, and believed in by others equally eminent, that reproduction is a wise contrivance of nature to make substantial use of the excess of strength and nutriment within the animal economy—that is, that an animal full grown and developed requires much less nourishment than when in the growing state; hence nature, abhorring all principles of wastefulness, develops the reproductive organs as a wise outlay for this excess—now it stands to reason that perfection in these organs, and in those processes accomplished by those organs, can only exist when all other parts are relatively perfect, performing their functions free from friction. The moment we depart from the natural principles of feeding an animal—whether for the specific object of making milk or making beef—we produce changes of condition within the animal, and those changes can never be for the better; certainly the desired ends may be attained, but all this entails friction—altered conditions of function, and the deprivation of the animal of a large amount of that strength and vigour so absolutely requisite to reproduce its species in a perfect manner.

Now, it would be exceedingly ostentatious on my part to expect that all artificial methods of feeding cattle could be done away with, and equally simple would it be on my part to recommend such. But, what I would urge is, that much may be done to mitigate the effects without seriously interfering with the objects directly sought. This, however, I shall consider further on.—*North British Agriculturist.*

INDIAN RAIYATS AND THE VILLAGE COMMUNITY.

(*Indian Forestry.*)

In your November number, a letter was written by "A. W. P." in the hopes of throwing some light on "the difficult problem of the regulation of cattle grazing" by a discussion in your paper. I thought at the time of reading his letter, and the very pertinent remarks that it contained, that I would add a rider to my own somewhat lengthy treatise on the "Deccan Pasture," which if it has not met the fate it merits in your waste paper basket, may be of some use to "A. W. P." I did not, however, add anything to that treatise, as I felt sure that some one would certainly have given your paper their ideas before this. Now that the February number has appeared, and still one writes, I have done so, as it is a subject in which I take a very great interest.

With reference to the first question, viz., was there an original arrangement for each village before British rule by which its own tract of forest was preserved as a source of wood for fuel and other domestic purposes besides grazing, &c.? Now I should say that no such arrangements ever existed, or we should certainly have seen it recorded by such officers as Grant-Duff, Francois, those of the Inam Commission, and authors of the village communities. In the first revenue reports for Satara and other Deccan Districts bordering on the Western Ghats with their immense forests, no mention is made of any communal system of forest protection. Whilst looking up the records of a Native State in the Konkan with the Kharbari, for the purposes of discovering what rules existed regarding forest lands, we did not find any that could lead us to imagine that communal forests existed in the past, or anything that had even a semblance to them. What did exist, and of which there is ample proof both in the Deccan and Konkan District records of English origin and the older native ones, was a keen appreciation of the value of timber and other forest produce. That this was so may be gleaned from the royalty on trees. Looking at old Sanads granted by the Peishwas, I find that only in very special cases was the right to forest produce as timber, &c., alienated from the Crown. Does not this show that under governments anterior to British that the Government was supposed to be the proprietor of all forests, and of certain trees even, that were not in forests? Of course lax supervision may have existed, but that the then government farmers or collectors of revenue exacted heavy mail on the forest produce goes without saying, and I therefore certainly agree with "A. W. P." that the forests in certain places were preserved owing rather to the fact that the population was more sparse and tenure of property less secure than at present. The rulers of the land who were proprietors of the forests, of course, did not object to the clearing of jungle for cultivation, as it paid them, still they never admitted the right of a commune to any forest produce beyond the free pastures of our present "mufat" lands, which are very limited in area.

The above necessarily entails my saying to "A. W. P." that there were no restrictions against people cultivating or grazing in forests, provided they paid their way under the native regime. Now it appears that even this restriction was removed under the British rule, and a premium put on the destruction of forest tracts. I know of several cases of forests having been thus destroyed under the British rule, that had been fairly well preserved under the native. That this protection arose from any foresight on the part of the native governments I am not ready to admit, but it was one source of protection.

I saw the statement once made in an administration report that a man lost his hand if he cut a tree under native rule; that this remark was true for the forests where the Angrias held sway I firmly believe, as I have heard the same on good authority, but then this punishment referred to large trees fit for ship-building. Probably the rajahs of old took similar precautions to ensure getting timber for building their palaces, for get timber they did, and of a size that one scarcely ever sees in the same place now-a-days. Sir William Wedderburn with all his love and keen appreciation of the native's good qualities, can never make me believe that the old native governments were patterns of peace, wisdom, and moderation with local self-government boards to look after the forests in each village.

"A. W. P." is right when he thinks that there were pieces of land outside the limits of a village. They exist to this very day, and there are many such pieces in the Deccan. They have of course under our present orderly government been constituted lands belonging to no particular village, and generally go under the name best suited to the locality, with the prefix or affix of "sheri." The derivation of this term I do not know for certain, but I have been given to understand that it refers to "dispute." It merely means that these lands, some of which are entire forests, belonged to no village at all, and that when pressure of cultivation in their neighbourhoods gave them a local value for grazing, &c., several adjoining villages began to wrangle for them. This would tend to show that previous to the wrangling, village boundaries were not continuous at any rate in the locality of these lands.

"A. W. P." says he has not seen Mr. Lee Warner's paper, "Persecution on the Western Ghats." I read it some months after it had appeared no one seems to have taken much notice of it. It was certainly beneath contempt, for a more offensive pamphlet written by an officer in Government service I never had the misfortune to read. It treated as a subject of which the author was piteously ignorant, when he broached the scientific points of kumri cultivation.

"A. W. P.'s" remarks regarding free permits need none from me. Forest officers know that every word he says on the subject only makes them see more clearly that the proper person to issue free grants is the forest officer, and not, as remarked in the last Bombay Administration Report, by the Conservator of Forests,

N. C., an official who wishes to gain cheap popularity by giving away property for which another is responsible."

"A. W. F." asks what are the best regulations for managing grazing? I have given my opinion, based on an experience of only seven years, in the pamphlet on Decan Pastures, and I therein advocate contracts for places where forests are large and supervision inadequate. Given a strong protective establishment of say one beat guard to every 4 square miles, then the fee system will be found infinitely more paying and more easily controlled perhaps than the grazing under the contract system is. Now registering by branding and marking cattle is out of the question. Just fancy the work! For each year a new brand would have to be made, poor brutes! A buffalo of 10 years' standing would look a sorry sight. I have some three lakhs of grazing in my present Division, and I think that about six lakhs of cattle graze on it. What would be the cost of branding these animals? I strongly recommend Divisional Officers to make the range officials issue printed passes to each man desiring to graze his cattle, with the number and kind entered thereon, and on the back of the pass an intimation should be printed to the effect that the person who lends the cattle must carry the pass on him. The Divisional Forest Officer has plenty of chances of dropping down on the grazer, let him then count the cattle and examine the pass. If anything is wrong the Divisional Forest Officer knows what to do, if he does not he is not worth his pay. One or two good examples that make all involved smart will very soon produce the desired effect, viz., that of Government of the present day protecting its forests and its grazing as of yore without the aid of any village communities.

R. A. FAGAN.

Nagar, 27th February, 1885.

REFINING OF SUGAR IN CUBA.

ITS FEASIBILITY AND ADVANTAGES FROM A CUBAN POINT OF VIEW.

In the *Nueva Era* (Boque) is an article, in which the writer of it discusses the *pros* and *cons* of the question. Many things look well on paper which do not hold good in practice. The cost of coal in a British or American refinery is a serious item, which the writer contends would be saved in Cuba, as megass would be burned. The cost of labour he estimates at one-half of what it is in the "States." In the case of the ordinary labourer this, no doubt, is so, so far as the cost per day goes; but what about the cost of skilled labour? The writer does not allude to the first cost of the plant, and, what is even more serious, the cost of keeping that plant in repair, which, we should say, will be three times what it is in England.

We should like to see the experiment tried. In these days it is not safe to say that anything cannot be done—but will it pay? We fully admit the force of many of the points which the writer of the article puts forward in favour of refining on the spot. We give a translation of the article:—

In spite of the general conviction, both in the United States and here, that it is not feasible to carry on economically the refining of the product on our sugar estates, the more we study the question, the more do we fail to find a single fact which would lead us to agree with that opinion, unless it is our want of practice and the knowledge of the best means of effecting the operation. Even supposing that it were necessary to confine ourselves to the same means and processes as are used by foreign refiners, we do not understand on what grounds can be based an exclusion which is injurious to the interests of both producer and consumer. The separation between the production of the raw material and its manufacture is intelligible, but it is inconceivable that a manufacturer should leave his work unfinished because he cannot finish it complete in one operation, and allow others to undo the product of his labour, in order to obtain a fresh profit, thus burdening the production of the article with the loss incident to a double manipulation.

The apparatus which the foreign refiners employ are not affected by climate, and would work here equally as well as in any other country. Labour at the old price costs one-half less than in the United States. The refiner has to buy the coal which he employs to convert into steam the water which is indispensable in refining our product, and however little per ton it may cost, it is an important expense which the producer here can save; for the bogsas of the cane which is worked up supplies all the fuel. The refiner suffers a considerable loss by the destructive effect of the sucrose of the second working—a loss which, in the refining of beet-root sugar, is calculated at 5 per cent, and if that on our products is less, it consists in this, that we sacrifice an equal amount to supply the Refiners' League of the United States with a product which polarises 97 to 99, whilst the white sugar which is sold there to the public frequently does not exceed 93—a sacrifice which, in the majority of cases, we make unconsciously—so that the difference between the refiner here and there is equal to the loss of 10 to 15 per cent of all our crop of sugar. The climate of this country is more favourable to clarifying, since our competitor has to obtain by artificial heat what the sun supplies to us here gratuitously. The tropical producer has every advantage in his favour, since he can save all the expenses of the second working, minus that of the movement of the bone-black in which operation he economises the half of the cost of labour, being able also to produce the black at less cost than here.

To all this there is a further important advantage to be added. It is well known that the purer the syrup the greater the production of sugar, and the less the yield of molasses; a difference which, in itself alone, compensates for the employ of bone-black, always provided it is effected with due economy.

It results, then, that we can avoid or make up for ALL the expenses of refining abroad, and sell white sugar which polarises 97 to 99,

That is to say, that we can produce the refined at about the same cost as centrifugals cost us to-day, gaining 10 to 15 per cent in the quantity produced.

We have in England a free market for this product, of which the refiner of a neighbouring country (the United States) now gets the advantage, and although it is true that he enjoys an indirect bounty in the return of the duty which the Government makes to him he pays double freight, commission, &c., whilst the producer of the article here can send it direct at less cost. This being so, we do not understand why the planter of the Island of Cuba should persist in protecting, on its actual market, the worst enemy which he has for the class of product which he supplies; for it is the refiner in the United States who does the most to impede the reduction of the duties in this country, and who is the only one who is interested in making obligatory the production of an inferior article. Before mentioning another proceeding which dispenses with the use of bone-black (an advantage of which the refiner is deprived by the density of syrup which he works up) we give an extract from a letter of the Commission nominated to investigate the adulterations, which are prejudicial to this industry.

It says:—"As one of the Commission nominated to investigate the polarization of refined sugars, I have to testify that after a minute examination, I have found that my former communication was about correct; for it results that the superior kinds of refined sugars do not exceed 98 per cent, and the remaining 4 per cent are owing, not to adulteration as previously supposed, but solely to water. The inferior grades polarise as low as 88 per cent, and the impurities in these sorts consist exclusively of an excess of molasses whitened in filtration through bone-black, and this is attained by giving a very fine grain and effecting the granulation at a very low temperature, which generally does not exceed 109° Fahr. and never exceeds 120°."

I am completely convinced that some refiners are in the habit of mixing white Louisiana sugars with inferior products before refining, to reduce the quantity of molasses. For example: if they are melting sorts which polarise 88 to 89 they mix them in equal quantities with those of Louisiana, which polarise 93 to 99, forcing these to appropriate a proportion of the molasses of the inferior sugar, obtaining thus a quality which only polarises 93 to 94. The difficulty in this operation is to get a sufficient quantity of the Louisiana product.

Here then is the explanation of the urgent need of the refiner obtaining in this market centrifugals of a high polarisation, causing the producer to convert 8 per cent to 10 per cent of the sucrose into molasses, forming an exceedingly coarse grain to convert it into fine grain, and sell 7 per cent to 8 per cent of the whitened molasses to the consumer as pure sugar.

That which we have brought forward up to now refers only to the case where the planter would be obliged to have recourse to the methods of operation employed by the refiner; but our arguments will have greater force the moment that he shall have at his disposal a much simpler, more economical, and more perfect process, such as, if our own information is correct, the discovery made by Dr. Isery and improved on by his successors.

We have at different times treated on this process, and shall now confine ourselves to saying that it is restricted to the separation by chemical means, in the state of cane liquor, of all impurities and colouring matters, reducing the juice at the first clarification to a simple mixture of sugar and water. This plan scarcely requires any addition to the apparatus in use at present, and to a great extent avoids the inversion of sucrose during concentration, an enormous advantage over the refiner, who, if we mistake not, is debared this benefit by the density of the liquid, to which economy in fuel obliges him to confine himself.

One of the sorts of refined sugar most in use is a white centrifugal which is prepared at about the same cost as the common centrifugal, since it is sold without being dried, and the *terron* can be manufactured without the expensive claying and clearance.

Whatever may be the quality of the product, the refiner, from motives easily comprehended, requires a package of small size and easily handled so as to find favour and a rapid sale. The consumer prefers to buy wholesale, but not in excessive quantities nor in a package which cannot be easily transported, and which would disturb his household arrangements, and the best refined sugar in the world, if it does not answer these requirements, is at an exceedingly disadvantage, because in the English market it is above all necessary to consult the convenience of the buyer. The custom of packing in sacks allows these to be used in place of casks, the obtaining of which in the island of Cuba presents some difficulties, not however insuperable, because they may come like the barrel staves from abroad.

All the modifications introduced into the manufacture during the last 15 years have been remarkably instrumental in preparing the way for refining on the estates where the sugar is produced, and the establishment of a modern refinery in the country will contribute to the change by demonstrating the possibility of doing so. It is to be hoped that before long those who have initiated this work will succeed in completing it, by adding a mill to the present plant and buying cane sufficient to boil down the product, avoiding the evaporation, unnecessary in this country, of the added water, and saving the greater part of the costs which are at present incurred by substituting bogsas for coal.

We hope that we have said sufficient to induce a more profound study of such an important question, not simply because it may increase the producer's profit, for the solution would involve another still more important. For some time sugar refining in a neighbouring country (United States) has ceased to be an industry in the true sense of the word, and become converted into a monopoly which prejudices the interests both of producer and consumer. It commenced by destroying the old sugar trade of the United States, which formerly lent its capital to the planter and assisted him in avoiding the sacrifice of the just value of his crops; and it is to-day the greatest hindrance to the producer in improving his

processes, by means of differential regulations, which compel him to convert himself up to a certain point into a manufacturer of molasses, destroying the better product, which had cost him so many sacrifices, to increase the profits of others.—*The Sugar Cane*.

EUCALYPTOGRAPHIA.

FRED. VON MÜLLER, has inaugurated a practice, alas! too late, to save the lives of many similar explorers either into new paths of geography or science. He has had the courage to stop his great work on Australian Eucalypts with the tenth decade just issued. Although from twenty to thirty species still remain to be described, they are so widely scattered, and apparently so unimportant, that the author feels delay in the completion of the present work to overtake their full diagnosis would only render it antiquated; so fast are facts and experiments of Eucalypt-growing in the most widely-scattered countries accumulating, that a new treatise will soon be imperative.

Amongst the chief trees figured and described in this decade are *E. acednoides*, "the White Mahogany" Eucalypt of New South Wales; *E. calophylla*, a close companion in the forest with the Jarrah; *E. eugenioides*, known in Queensland as the "White Stringybark Tree," attaining a height of about 200 feet; and *E. reclinata*, "Wandoo" or principal "White Gum-tree" of West Australia, yielding seasoned wood, weighing about 70 lbs. per cubic foot. It also describes *E. stricta*, found on the most elevated spots of the Blue Mountains (3,600 feet high), which is usually only 3 feet high, though it is sometimes found as tall as 20 feet.

Eucalypts should be felled about the close of the Australian summer, as the flow of sap is then least active. Care must be taken that the stems be not too severely shaken as they fall, if possible towards underwood, and away from stony or rocky soil—otherwise the value of the timber is deteriorated. This again should be sawn up at once after felling. The density of the wood prevents it being seasoned in ordinary fashion. Logs 3+2 inches should be covered over with sawdust for three months; those measuring 12+12 inches treated in the same way for twelve months; and this will prove abundant seasoning.

Mr. Brown has raised some thousands of Eucalypts by planting seeds in hollow stems of bamboo, or of *Arundo donax*, in which earth has been inserted, and which are afterwards placed vertically together. Young seedlings should be the height of a hand-breadth when transplanted, the roots being dipped in a puddle of earth and warm water, and partly left open. When sown in the open field, the side is first turned over by the plough, and a few seed grains planted at spaces four or five feet apart.

The purified Eucalyptus oil is not poisonous, and may be taken internally. It remains for some days undecomposed in the human system, according to evidence of the breath, but readily increases the temperature of the body by 2 Fahr. Abundant evidence is adduced in this volume of the therapeutic powers of a tree, to whose leaves the Baron applies the scriptural quotation "of being for the healing of the nations." Natives have by them, when steeped in hot water, closed ugly abdominal spear wounds in six days; professors testify to their relieving of ague pains and acute rheumatism; in some agues, Eucalyptus oil is placed before quinine; and it may replace carbolic acid in surgical operations.

The "Manna" Eucalypt, and the "Water" Eucalypt, from whose roots thirsty travellers are oft refreshed, are figured in this volume.—*Forestry*.

WOOD FOR WAR-SHIPS.

THE modern representatives of old Vulcan have not yet displaced the forester as a supplier of war material. Our great armoured turrets must have teak, or a similar wood, in some parts of their holds. If our Indian supply cannot avail for our needs, experience only points to *Oldania Africana*—African teak—once largely imported into Liverpool, now unavailable at easy distances on the shore, and the greenheart of British Guiana, as yet to be made an article of merchandise. Our Clyde and London steel building shipyards, now working night and day on Government contracts alone emphasize the importance of this question. Here, too, is a plea for such special Exhibitions as the late International one; and a very strong reason why permanent exhibits bearing on this very topic, now warehoused for want of funds, should at once be laid open for patient study.

Indian teak has bulked into prominence within the last quarter of a century. But the recognition of its money value almost dates contemporaneously with its introduction into commerce, hence rise in price and demand have almost been coincident. In Europe, the loads from 1874 to 1882 have ranged about 41,000, with one glaring exception, whilst the price has kept £13 per load, with the same difference. But in India there have been much wider oscillations. There the price has gradually precluded its use in railway operations; the Australian Jarrah becoming a rival. With us, a steady price means a continued adaptation of the wood to new uses. The growth of our commercial iron shipbuilding industry has, doubtless, been one factor. And now the stern necessities of war continue the demand, despite our long com-

mercial depression. While, then, the forests of this tree have had most telling inroads made on their area during the last decade, be it remembered that the high teak forest tree, the only one worth noting in this discussion, takes 80 or 120 years to grow—what then of supplies in the interval? The Forest service of India is here recognised as more than a necessity for its great country alone. It must solve this imperial question. For no extension of transport facilities from neighbouring countries can displace an Indian supply.

Mr. Simmonds's essay on this subject, given in the *Journal of the Society of Arts*, February 27, may be consulted by those wishing the statistics of the question. The following quotation must suffice:—

"Out of the total exported from India in 1883, 55,519 tons were shipped from ports to British Burmah, principally Moulmein, the rise in price from £7 6s. to £8 9s. per ton was said to be due to the falling off in the supplies of first-class timber and to the great difficulty which exists in getting the logs to market. The total output of teak in the year, as shown by the coasting trade exports, was 113,391 cubic tons, Bengal and Bombay receiving the bulk Madras and Sind taking only 15,000 tons. Great Britain took about 49,000 tons, and small shipments were made to Gibraltar (probably for orders), Ceylon, Sumatra, the Straits Settlements, and the Cape Colony. In 1884, 122,961 cubic tons of teak were brought coastwise into India. This is all sent from Burmah to Bengal, Bombay, Madras, and Sind, and the quantity thus consumed in the country is far larger than that exported to foreign countries.

"The rise of prices and decrease in the quantity shipped abroad, are an indication both of the increasing scarcity of this timber, and of the larger demand for it which has been created in India by the progress of construction. The scarcity, it must be said, is as yet manifested only so far as regards large logs; inferior and small logs are abundant enough still. Moulmein has already been deprived by Bangkok of this trade which it possessed until recently. The value has more than doubled in the last five years, owing to the large timber, convenient to the rivers, having now disappeared.

"The quantity of teak imported, by land, into India, was, in 1880-81, 116,737 tons; in 1881-82, 107,433 tons; in 1882-83, 121,714 tons; and in 1883-84, 180,205 tons, valued at £1,035,340."—*Forestry*.

THE FORESTRY CENSUS.

A WRITER in the *Philadelphia Press* summarizes the results contained in the concluding volume of this national undertaking:—

"Our forest wealth must be enormous to supply this immense annual yield, but how long it can endure this great and steadily-increasing drain is a question of vital moment. In regions lying along the coasts of both oceans, where the climatic conditions are most favourable to timber growth, the cutting of trees which have reached their prime entails no loss, and, if judiciously worked, permanent and productive forests could be maintained with profit in regions better adapted to their growth than to agriculture. When the prosperity of the State of Maine—founded on her once uninterrupted forests of spruce and pine—was threatened by wasteful cutting and burning, the forward-looking people of that State realized the danger, and a vigorous public sentiment soon operated to protect the scattered remnants of her primeval woods, and now the forests which were once held to be practically exhausted yield a large annual product. The example of Maine proves that original forests can be preserved and new ones established when the entire community realize that they are essential to material prosperity. But the forests which are sensibly and economically managed are discouragingly few. The white pine, our most important timber tree, has already practically disappeared from New York and New England, and little merchantable timber of this kind can now be found in Pennsylvania, where the pines once seemed inexhaustible. The maps in this volume show that the forests of Michigan, Wisconsin, and Minnesota which now furnish the bulk of white pine produced, are dangerously near to exhaustion. The best walnut, ash, cherry, and whitewood have already been culled from the hardwood forests of the Mississippi Valley. At the present rate of consumption the redwood forest of California will soon lose its commercial importance, and the extermination of the forests of the interior Pacific region seems inevitable.

The wasteful turpentine industry in the forests of southern pine, leaves the trees that have been boxed not only of inferior quality for lumber, but the trees, weakened by these gashes, are easily blown down by the first strong wind, or burned up by the fires which sweep through the resin-soaked debris. In the Southern Atlantic region and in the Californian mountains, roaming sheep, cattle, and horses destroy the hope of future timber growth by browsing off the seedling trees and barking the trunks of larger ones. Herds of swine tear up the young pines for their succulent roots and feed upon the edible fruit of many species. Worse than all, from burning brush, abandoned camp-fires, sparks from locomotives, herbage and underbrush burned over to improve forest pasturage and various other causes, fire is let loose in the woodlands, causing untold loss of timber directly, besides burning out of the very soil the ability to support forest growth, and leaving trees of the first economical value to be replaced by inferior species, like dwarf birch, popple, bird cherry, scrub oak, and lodge-pole pine. In our own State of Pennsylvania the immediate loss by forest fires during the census year was more than 3,000,000 dols., and more than 1000 square miles of woodland were burned over.—*Forestry*.

INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA:—SATURDAY, MAY 9, 1885.

[No. 19.]

Crop and Weather Report.

[FOR THE WEEK ENDING 29TH APRIL 1885.]

General Remarks.—Slight rain has fallen in parts of Madras, Bombay, the Central Provinces, and British Burmah. In the Punjab the fall has been general, except in a few districts. In Bengal rain fell in a dozen districts, but more is very urgently wanted throughout the Province. In Assam the fall has not been so heavy as in the two previous weeks.

Prospects remain unchanged in Madras, while in Mysore they are dependent on timely rainfall. Fodder is scarce in the latter Province. In Coorg the crops are in good condition.

In parts of Bombay the *rabi* harvest is still in progress, and preparations for the *kharif* continue. Scarcity of drinking-water and of fodder exists in places. The *rabi* harvest has been nearly completed in the Central Provinces and in the North-Western Provinces and Oudh, and is in active progress in the Punjab. Threshing and winnowing are in hand in the two former Provinces, and *kharif* operations have also commenced. In Hyderabad the harvest continues; and threshing has been completed in the Berars, where *kharif* preparations are taking place. In the Central India and Rajpootana States the harvest is over in some places, and continues in others.

Agricultural operations are progressing unsatisfactorily in Bengal, owing to the want of rain; harvesting of *boro* paddy continues. In Assam sowings have been nearly completed, and prospects are generally good.

The existence of cholera, small-pox, and fever is reported from nearly all provinces, though the public health is generally good.

Prices show a tendency to rise in Bengal, and are unsteady in the Punjab.

Madras.—General prospects fair, except in parts of Bellary and Anantapore.

Bombay.—Slight rain in parts of six districts. Standing crops slightly damaged by floods in parts of Kurrachee; *rabi* harvest still continues in parts of Surat, Shikarpore, and Upper Sind Frontier; preparations for *kharif* crops in progress in parts of five districts. Scarcity of drinking-water continues in parts of seven talukas of Dharwar and four of Belgaum, and of fodder in parts of three talukas of Dharwar and four of Belgaum. Cholera and small-pox in parts of thirteen, and fever and cattle-disease in parts of nine districts.

Bengal.—Rain fell in a dozen districts; it is very urgently wanted throughout the province. Agricultural operations are consequently not going on favourably; they are stopped in some places and standing crops have suffered; *boro* paddy is being harvested. Prices of food-grains show an advance in many districts. Public health generally good, though cholera and small-pox prevail.

N.-W. Provinces and Oudh.—Harvesting nearly completed. Markets well supplied and prices generally steady. Isolated cases of cholera and small-pox in some tahsils in Allahabad, otherwise public health fair.

Punjab.—Rain general throughout the province, except in the Delhi, Umballa, and Umritsur districts. Health good; a few cases of cholera at Sirsa, Lahore, Umballa, and Delhi districts, chiefly among pilgrims from Hurdwar. Crop prospects generally good, but damage to wheat expected in Sialkot district if more rain falls there; prices fluctuating.

Central Provinces.—Weather continues uncertain. Prospects unchanged. Cholera in Hoshungabad, Nimar, and Raipore; fever in Seoni. Prices steady.

British Burmah.—Slight cholera and small-pox in a few districts, otherwise public health good; health of cattle generally good.

Assam.—Weather cool. Sowing of *aws* crop almost over; prospects good. A few sporadic cases of cholera in the neighbourhood of Suddar station reported.

Mysore and Coorg.—Crops in good condition. Prices of food grains stationary. Prospects of season and public health good.

Berar and Hyderabad.—Weather warm. Threshing of *rabi* crops completed; preparations for *kharif* progressing. Wheat 22 and *juari* 26 seers per rupee.

Central India States.—Weather seasonable. Health good. Harvesting continues.

Rajpootana.—Weather seasonable, with cool breeze. *Rabi* harvest operations progressing.

Nepal.—Weather hot and dry. More rain wanted for the spring crops.

Letters to the Editor.

DESTRUCTION OF RATS WITHOUT INJURING TREES.

TO THE EDITOR.

SIR,—In a recent issue of the *Indian Daily News*, "A Florist" asks to know "how to get rid of rats without injuring the tree."

In reply, I would inform him, through the medium of your journal, of the method which my late father, Baboo Poran Chundra Dutta, the then principal flower merchant in British India, adopted successfully. He found in his Ooltadanga and Soorah plantations in 1870 that rats did considerable damage to the young Australian and country seedlings; but he succeeded in keeping them off from plants by simply putting round the root one or two pods of the cowhage (*Mucuna pruriens*.) The cowhage is a pod covered with stiff bristles, which, should they touch the hand or skin, cause violent itching. The pod is generally known to Europeans in this country by the name of *cow-itch*, which is, I believe, a corruption of its proper name.

For worms, &c., my father found the following a very effectual remedy:—He took equal parts of fine, well-ground *chunam* and salt, and mixing them well together, used to sprinkle the mixture on the ground round the roots of the plants. Having done this, he used to water the plants immediately, which caused the powder to sink into the ground, and killed the worms. This was done in all his Belgachia plantations, where he kept country seedlings. The worms used to eat the roots, but this remedy stopped their ravages at once. This may also prove effectual in the case of white-ants.

If "A Florist" wishes to know more about manuring, I shall be glad to furnish him with further information.

HEM CHUNDRA DUTTA.

Rughoo Nath Chatterjee's street, }
Malakar's Cottage, April 28, 1885. }

Editorial Notes.

It was noticed in a recent article how prominently the Punjab Government's recent Resolution on the wheat trade brings out the increasing importance of Kurrachee as a centre of the grain export. The same fact is shown very clearly by the statistics of the trade returns. In 1882, Kurrachee exported about half as much wheat as Bengal, and only a quarter as much as was despatched from Bombay. In 1883, it sent out more than half as much as the Bengal export, and more than a third of Bombay's. In 1884, its exports exceeded those of Bengal by 50 per cent, and exceeded the moiety of those from Bombay.

**

THE Madras Government, we are glad to find, have taken the initiative in abolishing a very inconvenient procedure observed in nearly all departments of Indian Agriculture. In a recent order issued by the Madras Government, it is pointed out that the continued disregard of the standing orders prohibiting the use of vernacular terms in English correspondence without an explanation of them, has attracted the attention of Government, and the Board of Revenue and other heads of departments have consequently been requested to issue fresh instructions to their subordinates prohibiting this practice.

It is stated that inconvenience is especially felt in regard to names of crops and trees, as totally different names are used to denote precisely the same thing in different districts, although in regard to trees there has been some improvement, botanical names now being frequently given. In furtherance of these orders, the Board of Revenue has been directed to draw up, in communication with the Director of Agriculture, a list of vernacular names of crops, with their botanical equivalents, for circulation to, and use by, Collectors and other officers in the Revenue Department.

THE wisdom of these orders is obvious, as it is very often very puzzling to find out the crops or trees referred to, from the vernacular terms used. We should recommend the other provinces to follow in the footsteps of the Madras Government in this respect.

CONTINUING our review of Mr. Ozanne's report, we find that he has devoted much attention to the improvement of wheats. He says Bombay wheats are mostly hard, and have consequently not found their way into the English markets to any great extent. From experiments conducted by Messrs. McDougal Brothers, who have given much encouragement to this very important staple, it has been found that the hard white and hard red varieties are specially fitted for the English markets. We are glad to find that measures for improvement have been taken in hand by the Bombay Chamber of Commerce, which has suggested the distribution of prizes for the best farmed fields. To this end a conditional contribution of Rs. 1,000 has been made, together with a promise of help to procure good seed. The Government have accepted the offer, and have allotted Rs. 10,000 yearly towards measures of improvement.

MR. OZANNE remarks, however, that the Chamber of Commerce has not been rightly informed regarding the admixture of hard and soft varieties of wheat which has been attributed to cultivators. He thinks that the theory of the so-called admixture is due to climatic influences, some evidence of which he pointed out last year in the pages of the *Indian Agriculturist*. He is, however, engaged in arranging for a thorough and systematic test on this very important point.

He strongly advocates the introduction of steam machinery for threshing and winnowing, and hopes are entertained of inducing Messrs. Balmer, Lawrie & Co., of this city, to set up one or two of their threshing machines next season. The experiment with the Cawnpore winnowers is said to have been disappointing.

IN selecting the best variety of wheat for experiment, Mr. Ozanne's choice fell on the soft white variety of the Central Provinces with some other hard white and red varieties. Of these, seeds to the quantity of 180 maunds was distributed, which was calculated, to sow over 300 acres. He does not think the plan of giving prizes for the best farmed fields will be practically possible, and points out some of the difficulties in the way.

THE export trade in wheat shows a falling off in the last year, 1884. Thus the figures for five years cited by Mr. Ozanne, give the following results;—

	Tons.
1880	73,349
1881	263,729
1882	316,718
1883	370,873
1884	272,153

There is no positive reason assigned for this decrease, which may, in some measure, be ascribed to the unusually fine crop of wheat last season in England.

THE experiments tried with the creeper known botanically as *ryptostegia grandiflora*, which yields a juice capable of being worked into India rubber, proved that although it

thrives well and is abundant in Poona and other places, yet it would not be profitable to make rubber from it.

A NEW departure in the crop and weather reports usually published in the *Gazette* is observable in the forecasts of wheat and cotton crops which Mr. Ozanne proposes in future to issue. These forecasts will be followed by harvest reports which will deal with the nature of the harvest, export demand, local prices, and quality of the year's produce. This is an innovation which will be looked upon with satisfaction by all interested in the subject.

WE now come to a very important portion of Mr. Ozanne's report, viz., Ensilage. Although while in England he was unable to visit any silos, yet he had heard and read enough to determine him to give a trial to the subject in this country. The experiment was carried out in converting a large iron tank into a silo. The tank was cylindrical, and made of boiler plate-iron, its cubic contents being 7,000 cubic feet. The stuff put in was jowari (*sorghum vulgare*), black jowari or Chinese sugar-cane (*sorghum saccharatum*), and bajri (*penicillaria spicata*). The area cut was 11½ acres, and the weight of the green stuff was estimated at 61 tons. The fodder was cut at the most favourable time, i. e., just as it was coming into flower.

THE crop was pitted whole, and took five days to fill in. The weighting averaged 200lb to the square foot. The temperature rose to 120 F. during the first three days after the silo was closed, and then fell to that of the outside air. About the same time a masonry silo was also filled. They were both filled in during September, and were opened in the January following. The iron silo however, was closed again, while the masonry one was kept open till June, by which time the ensilage was all consumed. The latter received 60,480lbs of very wet grass, and gave 49,486 lbs, or 82 per cent of ensilage, which was not a bad outturn.

THE important feature in this experiment was, that no deterioration was observed in the quality of the ensilage during the time the silo was kept open. The upper layer was found mouldy, but lower down it was good in color, but "very hot and steaming." There was also found to be a "decided sour smell." This smell was strikingly perceptible in the iron silo. Indeed, Mr. Ozanne says it was so strong as to be "decidedly disagreeable." The upper layers of about two inches were useless, but below, the colour is described as an excellent olive-green. The stocks of the Chinese sugar-cane tasted as sweet as when put in, which showed that the sugar had undergone no fermentation. This is considered an important point.

THE feeding result of these experiments is not very encouraging. An elephant fed for 15 days showed a falling off of 5 inches round the fore arm; but he is said to have consumed with avidity up to 400lbs per diem. 12 mules fed on 42 and 30lbs respectively per diem showed a decided falling off in condition, although their general appearances was greatly improved in the matter of their coats looking very sleek. The last experiment on sheep and slaughter cattle also compares unfavourably. They lost in weight, and their offal showed evident signs of the effect of the forage. They were quite black. It would have been interesting to know the cause of the peculiar effect of the ensilage in this instance. Mr. Ozanne would have added much importance to his experiments, had he ascertained the cause of these apparently *contrary* effects of the ensilage on cattle. But as he adds that he has undertaken more searching experiments, we shall no doubt hear something more of this hereafter.

THE enquiries under crop diseases and blight show that nearly all our staples are affected by some kind of disease or other. Mr. Ozanne's remarks on the subject are thoroughly practical, and we have some hope that, in the not distant future, some remedies may be found to rid these crops of their pests.

UNDER "Improved Agricultural Implements," we find that steam power is taking the place of bullock power. A sugar-cane mill is referred to which is obtainable at a cost of Rs. 200. It is plain that the sugar-cane mill in use in the Madras Presidency (which is referred to in another column) is not known in the Bombay Presidency. It has given such extensive satisfaction to the ryots and cultivators of sugar-cane, that we cannot help expressing some surprise that it finds no place in Mr. Ozanne's very able report.

UNDER "Cattle-breeding and Veterinary Establishment," we are told that much valuable information has been collected regarding the various breeds of cattle, which is, however, not given. A Veterinary Hospital and College under the educational Department has been sanctioned, together with a hospital for practice in connection with the Veterinary course at the College of Science, Agricultural Branch, under the Professor of Veterinary Science.

AGRICULTURAL and fiscal statistics, together with trade and trade statistics, have not been taken up for reasons given. Mr. Ozanne describes his report as "incomplete and sketchy," which is owing to the early date on which it was required to be out. We find, however, that a definite plan has been laid down, which is calculated to meet the end in view in future reports.

We cannot close this review without expressing our satisfaction with the thoroughly practical and interesting character of this report. As a first attempt, Mr. Ozanne has, in this particular direction, displayed a thorough ability to grapple with the multifarious subjects which come under his supervision. But in connection with such reports, we would invite Mr. Ozanne's attention to the report of the Department of Agriculture, Washington, which we have just received through the courtesy of G. B. Loring, Esq., the Commissioner of Agriculture, Washington. In a future issue we shall notice the character of this report.

THE methylation of spirits has occupied the attention of the Madras Government, it having been represented by the Commissioner of Salt and Abkari Revenue that the standing orders of the Board of Revenue, Madras, issued on the subject, have been found to be deficient, inasmuch as they do not provide whether the spirits to be methylated are to be of, or above, any fixed strength, or that the ingredients to be used for methylation shall be submitted to prior examination and approval by any competent person.

WITH reference to the first point, Mr. H. W. Bliss, the Commissioner, observes that the Calcutta Sea Customs rules lay down that no spirit of less strength than 30° over proof shall be methylated, while in England the required strength is not less than 50° over proof; and that the object no doubt is that the two substances to be mixed shall be as nearly as possible of the same specific gravity. While in regard to the second point, the standing order lays down that samples of the pyroxylic spirit or other ingredients used in the methylation of spirits, shall be retained by the gauger for testing the adulterant produced by importers, while in another standing order, there is only a general provision that 10 per cent of pyroxylic spirit, or such other ingredient as might be approved by the Chemical Examiner, shall be used.

MR. BLISS does not think that even the former provisions are adequate, as no testing by a gauger would be of any use unless he had some chemical knowledge, and possessed the necessary appliances. He has therefore suggested the amendment of the standing orders so as to provide that no spirits of less than 30° over proof be methylated; and that the pyroxylic spirit or other ingredient used in methylation, should, in the first instance, be sent to the Chemical Examiner, and after approval by him, be secured and kept in the custody of the gauger until required for use. He added that a similar provision exists in the Calcutta rules issued under Section 155 of Act VIII. of 1878.

THE Madras Government have approved the proposal made by Mr. Bliss, and recommended to the Government of India that rules in force in Calcutta on this subject may be extended to Madras, and the Government of India have sanctioned the recommendation.

THE agricultural statistics of Ireland bring to light some very interesting facts, not generally known. Thus we find that wheat cultivation shows a decided falling off. The area under wheat has decreased almost 30 per cent in one year. The area of the wheat crop during the nine years, from 1874 to 1882, is stated to have been on the average 150,000 acres, while in 1874, it had reached 189,000 acres. Since 1882 it has continued to decrease; thus in 1883, it had got down to 95,000 acres, which decreased further in the following year to 68,000. The cause of this steady falling off cannot be ascribed to any fault of the Irish farmers, as the outturn per acre has been maintained at an average of 14½ cwt., or 1,600 lb., which is a rate of produce about 50 per cent greater than that estimated for Indian wheat.

BARLEY seems to be much more widely grown in Ireland than wheat. During the years 1874 to 1881, the acreage averaged 220,000, which in 1882, however, fell to 187,000, and in 1884 to 167,000 acres. The most curious part of these statistics is that the so-called national staple-food of Ireland, potatoes, is not by any means the most widely grown crop in Ireland. Oats, which form the largest crop in Scotland, take the foremost place in Ireland also. Strange that the food of horses in England should form the largest item of man's food, both in Ireland and Scotland! but the fact is beyond doubt; for the acreage under oats covered no less than 1,480,000 acres in 1874, and 1,348,000 in 1884, which is far above that of barley and wheat.

POTATOES occupy only the limited space of 800,000 acres. We say "limited" advisedly, when compared with the acreage under oats. But it must be admitted that an acre of potatoes in Ireland produces a little more than 3 tons, which is nearly three times the average of an Indian crop of this tuber. The quality of the Indian potato cannot compare with anything like respectability with the Irish production.

NEXT in extent to potatoes, comes the turnip cultivation, which covered something like 339,000 acres in 1874, and 304,000 acres in 1884; thus showing a decided decrease, which commenced six years back. Flax is largely cultivated also, but it is confined almost entirely to Ulster; but the linen business has suffered somewhat from the dormant state of the trade. The cultivation of flax has steadily decreased from 157,000 acres in 1880, to 89,000 in 1884.

IT is clear that the figures given above show a decided falling off in every respect. The only crops which have maintained anything like a normal average during the past five years, are oats and potatoes, which form by far the largest proportion of the food of the poorest classes. The cheap foreign supply of wheat in late years, both in Ireland and England, has led to the abandonment of this crop in a marked degree. Apart, however, from this, the general decrease in area under crops of all kinds, brought to light by these statistics, discloses a very serious condition of things; while the extreme poverty of the West of Ireland is painfully manifest. The causes that have brought about such a state of affairs are too well known to require any remarks here.

MR. C. BENSON, Agricultural Reporter to the Government of Madras, in a letter which he has recently addressed to the Director of Revenue Settlement and Agriculture, makes the following remarks regarding the Rajahmundry Show, held on the 5th, 6th, and 7th April 1885:—"The show was practically the first of its sort, although last year an exhibition of garden produce was got up. It was confined to the stock and produce of the Northern Circars. The show of the former was, as might be expected, a poor one, as compared with what might be got together in other parts of the Presidency, the only cattle of special

merit being of the Nellore breed. One or two fair pony stallions were exhibited, but the sheep were few in numbers, and of very inferior quality. This, however, must not be taken as discouraging, as the main object of such shows is, I take it, to get together the best produce of the locality in which they are held. As a first attempt of private enterprise, even in this respect the show attained a fair degree of success. In future years if the Show is continued, the Committee will doubtless be able to do much more, and if aided, as I think they should be, by Government liberally, be able to frame a more attractive prize list, and so draw exhibits from a larger circle.

.

As regards the produce exhibited, I must observe that, as regards paddy, I was disappointed. Some very good samples of yellow cholum were shown and the cumbu was fair. In the pulses the exhibits were generally fair and clean samples. The oil-seeds were good; but few in number. The fibres revealed nothing new, nor were they well prepared. Some of the sugar-cane shown was very good, but the tobacco was scarcely ready for exhibition. Of oils, oil-cakes, and sugar or jaggery, the exhibition was very meagre. Regarding horticultural produce, I do not feel called upon to speak, especially as a good deal of the show in this respect consisted of European plants and vegetables. No prizes were offered for implements or machines, but Messrs. Massey and Co. sent up a few ploughs, and I expected that Messrs. Oakes and Co. would have done the same. Messrs. Bancroft sent the Hindustan plough. To supplement these intended exhibits, I sent up a few implements and two machines for display. One of the latter was injured in transit, but the other, a winnowing machine, attracted a good deal of attention. I sent up from Saidapet a set of samples of grains, cotton, oil-seed, &c., and of some fibres not usually made use of. On the 7th morning, a ploughing demonstration was held. I had no notice of this before I came up, and, although thinking one might possibly be held, I considered that, as a number of men from this district had been trained at Saidapet to plough, the revenue authorities would have provided competent ploughmen. None were, however, available. The demonstration was therefore held under unfavorable circumstances, especially as the time of year was also unsuitable, all ordinary arable land being unploughable. Notwithstanding this, what ploughs of Messrs. Massey's were on the ground were sold and orders booked for more. Altogether the show was satisfactory, although it might have been far better, and it is questionable whether it would not be well to devote a part of the annual grant for exhibition to the development of this show, and to endeavour to make it generally representative of the Northern Circars, and more general in its scope."

.

We quote below an extract from the notes of Messrs. McDougal Brothers, of London, on Indian wheats, dated the 15th March 1882, which forcibly shows the great superiority of Indian wheat over others. "In addition to the particulars contained in the foregoing returns, we have to report that to any one experienced in the requirements of the wheat and flour markets of the United Kingdom, and, indeed, of most other countries, it will be evident there is no probability of these Indian wheats coming into demand for manufacture into flour, without a liberal admixture of other wheats. They all possess, in a marked degree, the same characteristics of great dryness and a distinct beany and almost aromatic flavour, inseparable from wheats grown in the climates and soil of the tropics. Also the flours are ricey, the texture of the breads is too close, and the crust is hard and brittle. But these characteristics do not detract from their usefulness in any important degree. As is well-known, a miller cannot show skill in his craft to greater advantage or profit than that with which he selects his wheats, and mixes his grists so as to produce to best advantage a flour from which bread can be made of the colour, bloom, strength, and flavour desired, and withal a good yield. We pronounced them to be exceedingly useful wheats: in fact, hardly equalled for what is deficient and wanting in the English markets by any other wheats.

THEIR chief characteristics are just those in which the wheats grown in our variable climate are most deficient. Their great dryness and soundness renders them invaluable for admixture with English wheats that are in any degree out of condition through moisture, and the great proportion of the wheats harvested here have been in that condition for some years past—a condition that must prevail in all other than wheats harvested and stored during fine and favourable weather; and this the English farmer knows greatly to his cost, is a state of climate that is by a long way the exception rather than the rule. Added to their dryness, the thinness of the skins of these wheats and consequent greatness of the yield of flour must always place them in the front rank as a "miller's" wheat, whenever they are handled with reasonable intelligence and skill. Such unprecedented yields of flour, as are shown by these wheats, ranging (by ordinary grinding) from 77.46 to 80.52 per cent against English 65.2 and American spring 72.2, speaks volumes in their favour; and their value is still further increased by another point of merit of almost equal importance, viz., a larger percentage of bread may be obtained than from any other of the flours included in this review. That for the best of these Indian wheats (the fine soft white), on the day they were valued in Mark-lane Market, a price was offered as high as that for American winters, New Zealand or English (see list of values in synopsis), proves that the great value of the Indian wheat is becoming recognised here—a knowledge that will ere long extend to all our markets. The other lots of Indian wheats (Nos. 2, 3, and 4) were lower in value to the extent of four to five shillings per quarter, as might almost have been expected from the difference in colour and other characteristics: still, as these latter wheats become better known here, this difference in price will be somewhat lessened. Their beany flavour is not a serious obstacle, as fair average deliveries when well cleaned and properly dealt with can be employed in the proportion of 25 per cent to 50 per cent along with home grown or other wheats, such as American, possessing a fine, sweet, milky, or nutty flavour.

.

"Glancing at all the facts here elaborated, it is evident that these wheats afford a larger margin of profit, both to the miller and baker, than any other."

"We venture to record a conviction we have long held, strongly emphasized by the results of these experimental workings, of the measureless importance of the great resources of the Indian Empire being developed to the utmost in producing wheat for this country. Farmers here are finding that to live they must produce beef and mutton rather than grain: hence the greater need of resources of supply under our own control."

.

A CORRESPONDENT writes:—"The heat at Bangalore is phenomenal, and the folks at this favourite station are beginning to wonder what it all means. The good old-fashioned Bangalore climate has given place to a kind of qualified Bellary. Truly they managed these things better in the days of the Mysore Commission! As to water, that is a sore subject. Well after well dries up, and the cartmen have to go further and further to fill their barrels. Grass has long since disappeared. The Cubbon Park is the colour of an underdone chatty. The beautiful Lal Bagh itself is as dry as a cluder. In this last named once popular resort both fauna and flora look equally miserable. The antelope and sambur are tamer and sadder than ever, and the big cats in their dens are too exhausted to prowl up and down. Poor cats! How they must long for the jungle, with its cool earthy lairs, and leafy shade. If one ever could pity a tiger, that incarnation of cruelty, these are to be pitied."

.

A CURIOUS story comes to hand from Mysore. It appears that the jaghirdars of a large jagir village named Hoka in the Vanhat taluq of the Phansi sub-division, are far from satisfied with the terms on which they hold their lands from Government. Accordingly on April 1st, they held a meeting and elected a Panch, who were to consider the advisability of petitioning Government for the reduction of their juddi. The meeting was attended with some excitement, which was increased by the untimely appearance of Mr. Narsing Rao, the district officer. He seems to have acted rather unwisely in threatening immediately to attack all the jaghirdars

land of the *jaghirdars* (which is in arrears), and to drive them entirely to the *varkas*. This threat so incensed the *jaghirdars* that they drove Mr. Narsing Rao from the meeting, and pursued him through the village, waving their *takshins* and shouting fiercely. The unfortunate refugees found shelter in the house of a Mr. Sarendro Nath, who very properly refused to give him up, and who eventually prevailed upon the angry villagers to disperse. Mr. Narsing Rao then left the village after a detention of three hours. The matter is being strictly enquired into by order of Government, since this is not the first time that an affair of the sort has taken place in the district. It is just as well that the affair should have taken place upon the first of April.

.

In the Central Provinces, notwithstanding the injury done by rust in the northern districts, the prospects of the crop are still excellent. The area said to be under wheat (370,000 acres) is less than the reputed normal wheat area by about 200,000 acres, but the outturn is expected to be 817,857 tons or 14,286 tons above the average. The export during March was about 14,282 tons, but that for the first week in April amounted to 5,357 tons. In the Bombay Presidency and in the Berar, prospects remained unchanged at the date of the report. No fresh information has been received from any of the native States.

.

The *Times Democrat*, in describing the various exhibits in the World's Exposition at New Orleans, mentions a decorticating machine. The description given of it will, we think, interest many of our readers. The *Democrat* says of it:—"The machine is entitled the Universal Fibre Decorticator, which is manufactured by the Remington Agricultural Company, and was invented by Mr. T. Albee Smith, of Missouri. During the past month this decorticator has at times given displays of its qualities before numerous spectators, but on Thursday last it fairly astonished the seekers after fibre-preparing machines who were so fortunate as to witness its performances. The enterprising agent of the Remingtons, Major F. F. Hilder, anxious to test the capacity of the decorticator, had procured from British Honduras a quantity of *Bromelia sylvestris*, or silk grass leaves, banana and plantain stalks, and henequin or sisal hemp leaves.

.

It was generally known that the decorticator would be tested at 2 P. M., and quite a large crowd of experts was assembled, who were desirous of seeing it operate on green leaves. At length Mr. Smith placed several henequin leaves on the platform of the machine, which was set in motion, and in a few seconds the fibre was perfectly cleaned, without any perceptible waste. The silk grass leaves and plantain and banana stalks were also operated with the same result. Kentucky hemp (both rotted and in an unrotted condition) was thoroughly divested of its woody parts in one single and simple operation. The machine thus proved to the complete satisfaction of all who saw it work that it is, as it claims to be, a genuine universal decorticator. Mr. Albee Smith, the inventor, expects to procure green ramie stalks before the Exposition closes; and will demonstrate to the public the ability of the machine to prepare ramie for market in one operation. Green jute stalks may not be obtained in time to enable the machine to show its ability to clean that fibre also. As the product of dried jute stalks is only fit for paper-making, Mr. Smith does not care to bother with it. The universal decorticator, therefore, claims to successfully operate all green fibre plants, whether leaves or stalks. As fibre extracted from stalks contains more or less resinous gum, it must go through another process after it is decorticated to secure complete disintegration. Mr. Smith asserts that the jute fibre decorticated by his machine, after being steeped in water for a week, becomes thoroughly disintegrated, and is fit for market. The display made on Thursday proves conclusively that Mr. Smith's machine can successfully decorticate green fibrous plants. It is the only machine on exhibition that has attempted to work green material. Persons desiring further information regarding this decorticator can obtain it by addressing Major F. F. Hilder at the Remington exhibit in the Main Building, or at his office, 29, Poydras-street, this city.

THAT horrible vine-pest, the *phylloxera vastatrix*, has again been giving trouble in Australia. It appears that they have not yet done it with there. Some years ago the Parliament of South Australia agreed to contribute one-third of the expenses incurred by the Victorian Government in up-rooting the vines at Geelong, in which the *phylloxera* had made its appearance. The vinegrowers and the colony generally had reason to complain of the conduct of the sister colony in the matter. Instead of going to work with the energy required, Victoria remained shilly-shallying, and it was only as the result of repeated requests that she at last fulfilled her part of the bargain. The existence of the *phylloxera* in Geelong vines has been found to be a serious danger to South Australian vineyards, and experts agree that a policy of extermination is the only way of getting rid of the evil. It is stated that an experienced vine-grower who visited Geelong a couple of years ago found that this evil was still in existence. We are told that, roused partly by his representations, those interested in the same industry in Victoria put forth all their efforts to induce the Government to fulfil their promise. In this the Government was not entirely successful, and the *phylloxera* has not yet been eradicated.

.

This fact gives particular importance to the announcement that a strong movement is being made for the removal of the restriction on re-planting the Geelong vineyards. If it is true—and we see no reason to doubt the truth of the statement, made as it is by an authority on such matters—that suckers from some of the vines which had been cut down have sprung up with the *phylloxera* in them, the Victorian Government would be acting most unjustly if they removed the restriction. The colony is described as being interested strongly in the matter. It has contributed part of the money required, and the spread of the ravages of the *phylloxera* is looked upon as little less than a national calamity.

.

In connection with this subject, the following telegram appears in the *South Australian Register*:—"Mr. Bosisto, M.L.A., chemist, has, at the request of the Minister of Agriculture, reported upon the proposed mercurial remedy of Mr. J. A. Baner for *phylloxera*. Mr. Bosisto says the remedy would, in his opinion, prove most expensive and turn out worthless. The Minister of Agriculture has, in accordance with his promise to a deputation of vinegrowers from Geelong, appointed a Board to enquire into the whole question of the advisability of replanting the vines in Geelong district. The Board will consist of Messrs. Harris and Bosisto, M.L.A.s, L. L. Smith, and two gentlemen nominated respectively by the Melbourne and Geelong Vinegrowers' Association. The Geelong district will be visited and carefully inspected, and the fullest enquiries will be made with a view of ascertaining whether the replanting of vines may be permitted without running serious risk of promoting another outbreak of *phylloxera*. The colonies of New South Wales and South Australia, which contributed towards the expense of eradicating *phylloxera* in the Geelong district, are deeply interested in the question, and it is recognised by our Government that their wisest must be consulted in the matter before any important step is taken."

.

A CONTEMPORARY, writing of the American rice trade with England, says:—"America, long ago, ceased to export domestic rice in any quantities; and that of late years considerable of our supplies have been drawn from abroad, particularly low grades used for distilling and other kindred purposes. At one time Carolina rice was a feature in all English grocery stores, but the civil war completely ruined the trade. Its place has been taken up by Java and Japan rice, which sells at from 4½c. per pound. British India produces the bulk of the rice, which is known to the trade as Aracan and Rangoon. It sells in the London market cleaned ready for domestic use at from 2c. to 2½c. A cargo of uncleaned rice was recently sold in London at 6s. per cwt., or 1½c. per pound. This is the lowest price on record. There is a heavy duty on the rice imported into America. It is not generally known that rice forms the staple food of the greater part of the population of the world. In

British Burmah alone, the area under rice cultivation, the present season is 3,141,884 acres, an increase of 69,500 acres over last. The crop prospects are satisfactory, according to latest advices."

BEHEEA SUGAR MILLS.

THE Madras Government have, for the past two years, been engaged in conducting experiments with the Beheea Sugar Mills, patented by Messrs. Thomson and Mylne. Mr. W. Wilson, the Director of Revenue Settlement and Agriculture, Madras, to whom was entrusted the task of carrying out the experiments, has reported at some length on the result of his efforts to spread the use of this mill among the ryots.

It appears that in January 1883, the Collector of North Arcot asked the Board of Revenue to let him have one of these mills for exhibition in his district, wherein sugar was largely grown; and that, in compliance with his request, one of the old two-roller mills, that had been used in experiments at Bellary, was placed at his disposal. In May 1883, this officer reported that the mill was no longer required in North Arcot. Whether he had been successful or not in his efforts, is not known, as, from the correspondence before us, we are entirely in the dark.

Then it seems the Collector of Coimbatore expressed a desire to have the mill tried in his district, and it was accordingly sent to him. But here the results of the experiments were decidedly unsatisfactory, and contrary to the experience of all those reported from Bellary and Northern India. This appears to us to be passing strange; but the cause may be attributed, as Mr. Wilson says, to the fact of trundling about a solitary specimen of the mill from district to district, which, not to speak of the expense, was a slow and unsatisfactory way of bringing the mill to general notice. Whereupon, in October 1883, a letter was addressed to the patentees, suggesting that it would be to their advantage to take measures for the exhibition on their own account of their new-pattern three-roller mills in the sugar districts of the Madras Presidency, a list of which was furnished to them.

This suggestion was willingly responded to by the patentees, who explained at the same time that they had for some years been endeavouring to push their business in Madras, and had that year established a local agency at Madras, while in the previous year they had sold a good number of their mills in the Godavari district, at the head quarters of which (Coconada), they had also established an agency for the manufacture and sale of them, and where there were already 41 of them at work. Another encouraging feature in the more extensive use of these mills, which have been highly spoken of in many parts of Northern India, is that, on the application of the Collectors of Ganjam, Vizagapatam, Bellary, Cuddapa, South Arcot, Salem, Madura, and South Canara, Messrs. Thomson and Mylne have forwarded, at their own expense, mills for exhibition in those districts. Mr. Wilson says, that he has had no information as to the total number of mills sold from the first beginning of the enterprise up to September last; but from a return furnished to him by Messrs. Oakes & Co., the local agents at Madras, it appears that they had succeeded in selling 81 mills in the first eight months of 1884. Of this number, no less than seventy-five went to the Hospet taluk alone. There seems, no doubt, therefore, that the ryots have taken kindly to the new mills, and that their sale is extending.

A letter addressed by the agents of Messrs. Thomson and Mylne at Coconada, discloses the fact that the mill is in high favour with the cultivators of sugar-cane in the Godavari district. The agents say that they succeeded in selling, from December 1883 to March 1884, no less than 169 mills, "from their having been brought within the reach of ryots of ordinary circumstances." This fact speaks volumes in its favour. The following figures show the number of mills at work in the Godavari district since they were first introduced there:—

In the Season of 1882-83	48 mills.
Ditto 1883-84	169 "
Ditto 1884-85	190 "

It is stated that their sales have been recently affected by the decline in the price of sugar, and the consequent contraction of the sugar-cane area.

From the foregoing, we conclude that the Beheea sugar mill, as manufactured by Messrs. Thomson and Mylne, is a portable machine, easily worked, simple in its construction, and what is most important, "within the reach of ryots of ordinary circumstances." With these qualities to recommend it, the mill ought to take a prominent place amongst agricultural implements. In Bengal, Behar, Oudh, and the N.-W. P., where the sugar-cane is extensively cultivated, the ryots cannot do better than follow in the steps of their Godavari contemporaries. But in connection with this subject, we cannot close our remarks without observing that unless the district officers of these provinces emulate the example of the Madras Collectors, in prominently bringing the mill to the notice of sugar-cane cultivators, there can be little hope of these poor ignorant people becoming acquainted with its good qualities. The sugar industry in India is assuming such importance at the present time, from the fact of having a powerful rival in the beet sugar of France and Germany, and the Straits, that any improvement on the primitive methods of extracting the juice of the cane, will go far towards lessening the price of labour in its manufacture, thus rendering it proof against the encroachments of the beet.

GAMBOGE.

MR. R. A. MACK, writing on the 22nd ultimo on the subject of the gamboge of Burmah, says that although various varieties of gamboge-bearing trees have for many years past been known to exist in different parts of the province, notably in the Tenasserim division, it was not until comparatively recently that the subject was brought specially under the notice of the local Government. Writing more than thirty years ago, Mr. Simmonds, in his work, entitled *Commercial Products of the Vegetable Kingdom*, says: "The *Garcinia elliptica* of Tavoy and Moulmein affords gamboge and approaches very closely in its character to Graham's *Hebrodendron*;" and he adds that it affords "a fine pigment." Dr. Mason also, in his work on Burmah, remarks that "the best gamboge is produced by *Garcinia elliptica*, but an inferior article is produced by *G. cornea*, *G. anomala*, *G. cova*, *G. kydia*, *G. succifolia*, *G. xanthochymus*, and *G. (Hebrodendron) morella*. *Garcinia Gambogia* yields a pleasant fruit and a gamboge quite insoluble in water, and it is the complete solubility of the best gamboge that distinguishes it from inferior sorts, but it is probable that, when fully investigated, these insoluble gamboges will be found of service in the arts."

In 1875 Mr. Whittall, of the Forest Department, drew attention to three different species of trees, belonging to the genus *Garcinia*, growing in the districts of Southern Tenasserim. These were known to the natives as *Tawmengoat*, *Parawah*, and *Parajay*. The two last named Mr. Whittall did not consider of much account. The *Parawah* yields an exudation of a white colour, which changes to a reddish yellow on exposure to the atmosphere, and is scarcely at all soluble in water, but yields to alcohol. The *Parajay* yields a rather copious exudation which, when dissolved in spirits of turpentine, affords a beautiful, permanent, yellow varnish for metallic surfaces, and on this account has been called the gamboge tree as well as the yellow-varnish tree; but its exudation does not form an emulsion with water, and, for this and other reasons, Mr. Whittall considered it had no claim to be considered a real gamboge tree. The *Tawmengoat* was, in Mr. Whittall's opinion, the gamboge tree of the South Tenasserim forests. He says: "the gum resin is larger in quantity and darker and of more glossy colour than the others: neither wet nor dry is it so sticky, and so readily does it form an emulsion with water that the exudation on the outer bark is completely washed away by the rains." This tree he believed to be the same as that which Dr. Mason calls *Thanatam* (*Garcinia elliptica*) [*G. heterandra*], and he adds that it was supposed to be the same as that which yields the gum resin exported from Siam. But Mr. Hill, Officiating Conservator of Forests, Pegu Circle, thinks the

Tawmangoot is probably the *G. Morella* or *pictura*, or *gutta*, the true gamboge tree, which does not grow all over Burmah like *G. elliptica* or *G. oowa* which latter are common trees throughout the province.

In May 1864 the Commissioner of Tenasserim drew the attention of District Officers to the trees called *Thaungthaleh* (*G. kydia*) and *Thanataw* (*G. elliptica*) found growing in the tropical forests of Martaban and Tenasserim with the view, if possible, of developing a new industry for the people. Of the former Mr. Hill says: "It yields a yellow substance of a bright colour, but paler than the gamboge of Siam. It is scarcely soluble in water, but dissolves in spirits of turpentine, and affords a beautiful, permanent, yellow varnish for metallic surfaces. As the substance is very resinous and will not dissolve in water, it is valueless as a pigment." Of the latter he remarks: "The product known as *Thanataw* is obtained from *G. elliptica* or *hetrantra*. It is called a superior gamboge, but in all probability merits the name almost as little as *Thaungthaleh*, owing to its only partial solubility in water. It is found throughout the province, and is darker in colour than *Thaungthaleh*. A sample of *Thanataw* obtained from Tavoy was found upon analysis to contain—

Resin	76.5
Gum	23.5

This sample was sent to Calcutta for valuation, where it was declared to be gamboge, but unsaleable in an unrefined state. In August of the same year samples of gum produced from two other kinds of trees called *Palagyi* and *Tawmangoot* were also obtained and submitted for analysis. They were found to contain—

			<i>Palagyi.</i>	<i>Tawmangoot.</i>
Resin	58.32	53.20
Gum	9.54	20.30
Water	32.66	25.60

In his report on these samples Dr. Romanis, the Chemical Examiner, says the yellow kind (*Tawmangoot*) makes a very fair paint, but the other is of no use. If the gum is extracted, it makes a spirit varnish, but when warm it melts and gets sticky.

According to the broker's report, to whom the sample of *Thanataw* referred to above was submitted for valuation, gamboge in its refined state sells in the Calcutta market at from Rs. 2 to Rs. 2-8-0 per seer. It arrives there freely from June to August, usually packed in cases of from three to four maunds, and it is chiefly used in French polish and paint. In Burmah the cost of collection alone is estimated by the Deputy Commissioner, Tavoy, at Rs. 25 per viss (3-65lbs). That is to say, the cost of collection amount to nearly Rs. 7 per lb., while the market value of the product is only Rs. 1-4-0 per lb. and that too when it is in a refined state. It does not appear why the cost of collection is so great. In Ceylon the process of collection is very simple. There the gamboge is usually collected by cutting a thin slice of the bark of the tree here and there of the size of the palm of the hand. On the flat space thus exposed the gum collects and is scraped off when sufficiently dried. It may be possible perhaps to reduce the cost of collection. Unless it can be reduced very considerably, we cannot hope to introduce the Burmah product into the market. From the enquiries made, then, it would appear that the *Tawmangoot* alone yields good gamboge, and that the only obstacle in the way of the gamboge succeeding as a commercial product is the high cost of collecting it. The products of the other trees mentioned are not promising because of their comparative insolubility in water.

AGRICULTURAL DEPARTMENT OF BENGAL.

ONE of the most important results of the late Famine Commission has been the establishment of Agricultural Departments in the several provinces in India. By a strange and unaccountable omission, however, Bengal has hitherto remained without a separate department, till the subject was taken up by the present Lieutenant-Governor who, in June 1863, sent in a proposal for the consideration of the Government of India, based on the recommendations of the Famine Commissioners, as ap-

proved by the Secretary of State, and which may be broadly summed up as follows:—

1. The collection and embodiment in convenient forms of statistics of vital, agricultural, and economic facts.
2. The general improvement of Indian agriculture, with a view to increasing the food-supply and general resources of the people.
3. The organization of famine relief.

The Lieutenant-Governor's proposal fell under two heads—Agricultural Research and Agricultural Improvements. Under the former head, Sir Rivers Thompson's recommendations embraced the necessity of providing a local agency for the ascertainment of agricultural facts, and for the maintenance of the village records of rights, without which it would be impossible, he said, to acquire in a continuous and methodical way, any trustworthy statistical information in Bengal, owing to the absence of proper agency for the purpose. In regard to the question of *Agricultural Improvements*, the Lieutenant-Governor had indicated the duties which would devolve on the Agricultural Department in dealing with that question, and also in promoting the more enlightened administration in Government and Court of Wards estates. On all these points, the local Government received the general support of the Government of India, embodied in a despatch to the Secretary of State. Lord Kimberley, while admitting the beneficial effects of a general field survey of Bengal, and the establishment of a system of detailed village records, was unable to sanction an undertaking of such magnitude until he had been put in possession of facts in connection with the methods to be adopted in carrying it into execution, the expenditure likely to be incurred, and the difficulties that would have to be met. But at the same time, he admitted the "importance of providing the Lieutenant-Governor with the requisite agency for advising the Government generally in all matters relating to agriculture and statistics, as well as for undertaking the preliminary enquiries which the Lieutenant-Governor may consider necessary in connection with experimental field survey in the Patna division, and the enquiries mentioned in connection with the creation of a village agency of account in Government and Wards estates." His lordship also observed that "in the absence of these means of obtaining a satisfactory knowledge of the agricultural statistics of Bengal, which are supplied by the revenue organization of other Provinces, it is all the more desirable that every effect should be made to supply this essential requisite of good government." In accordance with their resolution, the Government of India sanctioned the appointment for two years of a special officer to advise the Lieutenant-Governor, in matters, relating to agriculture and statistics, to undertake the preliminaries in connection with the experimental field survey of the Patna division which has been sanctioned by the Secretary of State, and to assist in obtaining the detailed information called for by the Secretary of State in regard to the creation of a local agency of record in Wards' and Government estates. Under these conditions, the Agricultural Department of Bengal has come into existence as a tentative measure, and a special officer, styled the Director of Agriculture, has been appointed. His attention will be directed to both agricultural research and agricultural improvement. In regard to the former, he will have to address himself to carry out the experimental survey, under chapter X of the Tenancy Bill, by professional agency, particulars of which are given in the Resolution. Before finally determining the method of preparing the record of rights, and the system of local agency to maintain them when completed, the Director will ascertain by personal inspection what is the most approved practice in the North-West Provinces where the same work is in progress now, and report upon it. Another matter with which he shall have to deal is the question of the market prices of staple food crops; and it will be one of his first duties to enquire into the existing machinery for ascertaining and recording prices, to frame proposals for its amendment where this is found to be necessary, and generally to set on foot, under the directions of the Board of Revenue, arrangements in accordance with the provisions of the law for the systematic and continuous record, verification, and publication of the prices-current of staple food crops.

GLANDERS has broken out amongst transport donkeys at Meer Meer.

THE Viceroy opens the Ripon Hospital at Simla on Thursday afternoon the 14th instant.

A SILK manufactory is to be established in Riukin, Japan, to afford employment for the poorer class of *shizoku*.

THE Soldiers' Exhibition, which was to have been held at Bangalore in October next, has been postponed.

DURING the month of March, 120,978 bales of cotton, valued at Rs. 1,13,50,243, were shipped from Bombay.

THE Madras Municipality have farmed the lotus leaves and flowers growing in the People's and Napier Parks to a contractor.

MR. J. W. P. MUIR-MACKENZIE, Forest Settlement and Demarcation Officer, Sattara, is allowed furlough for thirty months from the 23rd May.

THE latest official census of Japan reports a total population of 37,442,966, of whom 18,492,807 are females. The number of houses in the country is 7,674,224.

THE Madras Government have sanctioned the sum of Rs. 850, asked for by the Superintendent, for the examination and protection of the pearl banks near Tuticorin.

It is stated that the French are about to form at Hanoi an Agricultural and Industrial Association, the object of which is the development of the resources of Tonquin.

THE shipments of new season's tea from Canton to London, up to the 14th of April, were 30,925 lbs. At the same date last season the shipments had amounted to 395,011 lbs.

A SOCIETY of *shizoku* in Nagashima, Japan, proposes to engage in the breeding of silk-worms on a large scale, and a Government grant of 100,000 yen, in aid of the enterprise, is expected.

THE loss to the British trade, says an Italian journal, since the commencement of the Franco China war, amounts to an average of £2,000,000 per month or £24,000,000 per annum.

THE S. S. *Olan Matheson*, which arrived in the Madras roads lately from London, has brought 3,300 cast iron railway plate sleepers and 6,700 packages of telegraph stores.

AN exhibition of articles connected with the silk and porcelain industries will be opened at Uyeno, Tokyo, Japan, on the 1st of March, under the auspices of his Excellency Count Matsugata.

THE subscription raised in Saigon for the relief of the sufferers by the recent inundation in Pondichery and Karikal amounted to \$1,020. This amount has been remitted to the Governor of Pondichery.

A HUGE drum, nearly eight feet in diameter, anciently used for religious ceremonies at the Imperial Court in Kiyoto, is to be sent from Japan to the impending exhibition of musical instruments in London.

THE attendance at the Mogalbhia Fair, which lasted from the 14th to the 16th March, is said to have been about 3,000, and the estimated value of property which was sold on the occasion was Rs. 3,000.

THE Government of Madras has consented to grant advances to certain sufferers from the breaching of the Red Hills tank, for the purchase of cattle and seed-grain, free of interest, to be repaid by fixed instalments in four years.

A CIRCULAR has issued from the Financial Department, warning all departments to economise and cut down expenditure in every direction—a necessary corollary of the sudden strain upon the finances of India for warlike preparations.

AT this season, large quantities of mangoes, in all stages of maturity from the small green fruit (*khairi*) to the large ripe, deep-tinted pairi, were usually to be seen all over the place. (Bangalore.) But this year, with the exception of a few small green mangoes, none can be had.

THE Oossoor Remount Depot has been drained of all its horses to supply Cavalry and Artillery regiments of the Army Corps at Quetta. The other day a special train was timed to leave Maloor, with a large batch of horses from Oossoor for Bombay, en route to Quetta.

THE *Penang Gazette* regrets to learn that owing to the depression in the Sugar market throughout the world it has been decided by one of the largest European Sugar Companies to at once close one of its estates in Province Wellesley; and we understand further that, according to information just to hand from London, a resolution has been come to, to the effect that, if no improvement takes place in the market soon, all the other estates of the Company will be also wound up.

Since the transfer of Mr. Sanderson to Dakka, wild elephants in parts of Maisur are said to have increased to such an extent that the duties of the dak runners and the Forest officers cannot be performed in the Kadur district, whilst in other parts the intercourse of the inhabitants of almost adjacent villages has been put a stop to.

RATHER an unusual occurrence was witnessed lately at the village of Nandose, Havili Taluka, when a field of dry grass caught fire and blazed away for hours, extending over something like a hundred acres. The simple villagers were unable to cope with the fire, which died away as spontaneously as it seems to have sprung up.

A LAHORE correspondent writes that the Cashmere Durbar, in pursuance of their policy of opposition to the extension of trade, have made an unwarranted attack on Mr. Russell who had formed a new trading company under the patronage of Sir Oliver St. John. The matter has been represented to the Viceroy, and will probably result in heavy litigation.

It will be news to the Bengal Chamber of Commerce to hear that it "cordially approved" of the recent proposal to establish a value-payable post with England. This is the case, however, according to the leading Madras paper, which claims for the Madras Chamber the exclusive credit of having brought about the decision of the Government of India to negative the proposal.—*Englishman*.

WE hear from Pondicherry that great complaints are made against the quality of the salt now being delivered by the British Government. Experts say it is a mixture of sea and spontaneous or earth salt, is prejudicial to health, and produces eruptions and skin diseases. Formerly the supply for Pondichery was drawn from Mercanam, but since the closing of that depot, it has, we understand, come from Madras.

THE results of the late floods in Tanjore, as described in a report by the Collector of the district, were that the whole tract of country bordering on the sea-coast, about 60 miles from north to south by 10 to 15 miles from east to west, comprising the greater part of the Tiruturpundi Taluk, a large portion of Negapatam, parts of Nannilam, Mayavaram, and Shiyali, as well as a great portion of the Mannargudi Taluk, was submerged, and the crops over an area of more than 248 square miles were more or less destroyed.

ARRANGEMENTS are being made for the construction of a Vegetable and Fruit Market, at Poona, a convenience very much needed, especially during the monsoons. Much smaller stations than Poona can boast of well-built markets such as Ahmednugger and other places; and why should not Poona have one in the City, and another in the Cantonment? The present low, miserable huts used by sellers of vegetables and fruits are not at all suitable, and the sooner we have a regular market for the sale of these commodities the better.

THE Chief Engineer for Irrigation has recently submitted to Government a note on a report of the Superintending Engineer regarding the Mylapore tank. The Government accepts the suggestions of the Chief Engineer for Irrigation. The Collector will accordingly arrange to take charge of all tanks in the Madras district, and submit revised proposals for watching the bank of the Mylapore tank when full. He will, of course, seek for the advice of the Public Works officers when any work requiring professional advice has to be executed.

THE Commissioner of the Patna Division is having a careful watch kept upon the tracts affected by the drought of last year. In a report to Government, dated March 30th, Mr. Halliday says "the Sub-Divisional Officer of Behar has personally enquired into the condition of a large number of villages, with the general result that there is at last a tolerable *rabt* crop in his sub-division, and that there is no real distress at present. The water-supply is evidently running short in many places, but it does not seem to be exhausted anywhere as yet.

MR. KAIKHOSE N. KARRAJEE, Editor of the *Rast Goftar*, has opened a subscription for the presentation of a rifle to Mr. Hormusjee Eduljee Kotwal, employed in the Forest Department of the Native State of Vansda, who has killed over one hundred tigers in and about the native territory. Mr. Kotwal's prowess in slaying such a large number of tigers has been highly spoken of by local sportsmen, and it is with a view to showing an appreciation of his services to humanity that a modest sum of about three or four hundred rupees is invited from the public.

THE Cashmere Government is averse to foreigners acquiring territorial rights at Srinugger, but would be considerably annoyed, no doubt, at any hint of reciprocity. His Highness the Maharaja of Cashmere has been at some pains to acquire house property in Lahore; and besides houses, owns the seral known as the Sultan Serai. As regards the latter—which is an Indian version of Punch's "Mud Salad Market"—his Highness can hardly be regarded as a model landlord. The state of the Sultan Serai is occupying the serious attention of the Lahore Municipality, and it was high time, indeed, that something was done to deal with what is nothing short of a grave danger to the public health.

WE understand that the Jhelum authorities have made an enquiry into the case of Geba, the man who found his way to England, in order to complain of the injustice done to him in transferring his claim to some seven bigas of land to powerful and hostile neighbors. He walked from Jhelum to Bombay; there was taken on board a

ship for Jeddah; walked thence to Jaffa, and got a passage to Constantinople, whence he wandered through Turkey and Hungary where he was charitably received. He then walked through the length of Germany to Hamburg, and was thence forwarded to England, which he reached three years after leaving Jhelum. There seems to be a probability that he has been the victim of a conspiracy, which prevents his obtaining evidence in his favor, and, even should he return, he may not be able to contend against the hostile faction, unless they are bound over by the authorities to keep the peace, in order to enable him to prove his case. In any case it would be better for Gaba to turn to the Punjab, and we hope that the authorities will override any technicalities for the sake of awarding substantial justice to a petitioner whose poverty and ignorance may have prevented his obtaining legal redress hitherto.

Selections.

REFLECTIONS ON THE RELATIVE POSITIONS OF BEET SUGAR AND CANE SUGAR, AS PRODUCED RESPECTIVELY FOR REFINING PURPOSES IN GERMANY AND DEMERARA.

By WM. RUSSELL, Demerara.

It is of the utmost importance to our sugar colonies, to know at what price beet sugar can be sold, so as to leave a working profit. Many statements, some very absurd ones, have been made upon this point.

In order to ascertain the real state of the case, Mr. Russell, of Demerara, has recently paid a visit to the beet sugar centres of the continent, and has printed, in pamphlet form, for private circulation, the results of his valuable investigations. He sets forth the advantages and disadvantages of both the cane and the beet industries, and upon weighing them finds them very evenly balanced; still, with strict economy and the best machinery, the conclusion he has come to is,—that cane growers may yet hold their own against their formidable beet competitors.

[With Mr. Russell's permission we are able to reproduce his valuable paper.—Ed., S.O.]

The present state of the sugar trade, when the smaller islands of the Antilles must give up that industry, and even the fine Colonies of Trinidad and British Guiana, with all the superior machinery lately introduced there, cannot produce sugar within £5 per ton of present prices, which are, say £14 to £17 per ton in England, according to quality, has assumed a much more serious aspect than onlookers can have any idea of, because in our West Indian possessions there is no other industry which can be taken up to replace sugar-cane. Cotton and Coffee in the past had to succumb for want of labour. Under these circumstances, the writer thought it good to make himself personally acquainted with the beet industry in all its bearings, and with that object in view he lately devoted some weeks to investigate the matter in the beet sugar producing districts of North Germany. After much intercourse with agriculturists, engineers, and manufacturers of sugar in its various forms, he was led to the following reflections:—

Industrious Habits of the People.—This must strike the most casual observer. From the dog which watches the steading by night and draws its little cartload of market produce by day, to the cow which gives up its milk in the morning, and then goes out to work on the land,—from the head of the household to the urchin who plods to school,—all are workers. In the large agricultural villages which have sprung up in many small principalities abounding in Germany, the people have allotments of land, often peculiar in outline and of limited area. In these patches one sees all kinds of produce—cabbages, potatoes, cereals, but invariably a plot of sugar beet, this being to the German, what the pig is to the Irishman, ready money; because at no great distance from these communities is sure to stand one of those huge factories for converting the roots into sugar, where ready money is paid for the roots when delivered.

Labour Question.—This seems reduced to a very low standpoint. 1s. 6d. (eighteen pence) with potatoes, light, and lodgings for men working in the sugar factories, 11 hour spells is a long way below West Indian rates, and for scientific men, such as working chemists, a salary of £6 per month with board is certainly under what is paid in any other country. The hands on the farms seem well clad, and their fare, although common, keeps them in robust health. Apparently they are equally efficient with our English agricultural population.

Large Farms.—These extend to about 5,000 morgens and over, say, up to 3,000 English acres, and over, and are conducted on sound principles, the three-shift rotation predominating, i. e., one-third of the land being in cereals, and very little grass, one-third in potatoes, and one-third in sugar beet. Thus the land runs no chance of being stinked by continual cropping of one product. The straw manure, of which a large quantity is made by bullocks, which are chiefly fed on exhausted beet slices, and also by the large number of work animals, is all used for the potato and cereal crops—the beets being manured by nitrogenous and superphosphate manures, three hundred-weights of nitrate of soda and two of superphosphate to the morgen being an ordinary dose.

Quality and Cost of Land.—The heavy loam in the valleys of the Rhine, Elbe and other rivers, is considered the best for the growth of beet, and such lands sell as high as £150 per English acre. Sandy soil, of which one sees a vast extent, is worth £20 to £100 per acre, and the latter class of land, where properly manured,

and with a favourable seed time with sufficient moisture to start the plants, gives excellent crops of sweet roots, this being the great desideratum in beet culture. Anything over 10 tons of roots per morgen is looked upon with disfavour by the manufacturer of sugar, as the larger the roots are the more water they contain in proportion to the sugar, and he would thus be paying duty on an extra quantity of water. In fact, the manufacturer insists upon supplying the seed, it being secured from improved roots that have been selected from time to time on chemical analysis, until it is not uncommon now to find roots analyzing as high as 17 per cent of sugar against 7 to 8 per cent when the roots were originally taken in hand as a raw product from which to extract sugar.

Extent of Beet Culture.—The Government statistics for the 1882-83 campaign gave an average of 9½ tons of beet-roots per morgen, which, in round numbers, gave one ton of sugar, 5½ cwt. of molasses, and 4 tons of cattle food. Licht's forecast of the present campaign, 1884-85, puts the German crop at 1,100,000 tons of sugar; this represents 1,100,000 morgens in beet cultivation. Even this is exceeded by 50,000 tons in Licht's circular for January of this year.

Factories.—These are computed at 332, of which no less than 35 new ones were erected last year, at a cost of £1,000,000 sterling. This gave rise to an extension of cultivation to the extent of beet requisite to make 145,000 tons of sugar over that of the campaign of 1883-84, which latter was 986,403 tons. Here we see that the high prices of sugar ruling for the previous two years, coupled with the increased richness of the roots and reduced cost of manufacture into sugar, and also with the improved appliances to work over the molasses, gave such a stimulus to production, that if such prices had continued for a few years, Germany would have increased the production even faster than it did for the last three years, during which it has risen by immense strides from 644,775 tons in 1881-82, to the expected crop of 1,100,000 in 1884-85.

The following calculations are based on—

A morgen = 6/10 of an English acre.

A mark = 1 shilling.

A centner = 1 cwt. English.

Cost of cultivation per morgen—

Rent	marks 36
Ploughing	12
Hand Weeding	8
Artificial Manure	30
Grubbing	10
Singling and Weeding	2
Pulling and Carrying	10
Carrying to Factory	15
Discharging	2

125 shillings.

By 9½ tons
of beet per } = 190 cwt. at 1s. 3d. stg. ... 237-6
morgen

Farmer's profits per morgen ... 112-6 or £5-12-6

This seems at first sight an immense profit, but when it is taken into account that the beet-roots only cover one-third of the farm, and that the other two-thirds do not do much more than pay expenses—also that no charge is included for management, tear and wear of stock, and interest on farmer's capital, it sinks considerably. Thus the profit of £5 12s. 6d. per morgen on the beet, divided over the whole area under cultivation, gives an average all over of 37s. 6d. per morgen, or a sum about equal to the rent paid.

1 8 0 per ton.

Natural Loss on Free Trade principle ... £4 6 4 per ton.
To which should be added extra charges to port of shipment, in the case of factories at a distance from Hamburg.

It would then seem that the present price of sugar is four pounds six shillings and four pence per ton, under the cost of production in

well-managed factories—a state of things which cannot last, however anxious the continental nations may be to kill out the sugar-cane production and so have the market in their own hands.

Sugar from Molasses.—The 3 % of molasses on the weight of the roots contains about 50 % of sugar, and this is purchased by a new set of manufacturers who, by a chemical process, recover 30 % of the contained sugar as exportable sugar, and upon this sugar, which sells in the Clyde at 8s. to 8s. 6d. per cwt., they get a drawback from the Government of 9s. per cwt. This is decidedly the strangest anomaly of all, and cannot be allowed to remain in force, as the fabricants are clamouring against it. It is quite true that the roots, having once paid the duty, the fabricant is at liberty to make the most out of them which well directed science indicates; but it clearly robs the revenue in a double way, for when the present fiscal tariff was arranged, it was considered that 12 tons of beet would be necessary to make a ton of sugar, which, at 9d. per cwt. duty on beets, would entitle the exporter to a drawback of £9 per ton only, and that there would be 7½ cwt. molasses to go to the distilleries, on which a revenue would be recovered. Now this is evaded, and the product is manipulated into an article worth less than the drawback allowed upon it. This drawback was maintained at £9 per ton after the duty on beets had been raised to its present figure of 9d/10d. per cwt.

German Consumption of Sugar.—This is given as 16 pounds per head, and the selling price in Germany is one penny per pound higher than in Great Britain, so that the tax upon the sugar beet causes a direct tax on the consumers of 1s. 6d. per annum. Taking the population of Germany at 42½ millions at 16 pounds per head, home consumption is roughly 800,000 tons, leaving 800,000 tons for export, on which a drawback of £1 8s. over the duty collected, or £1,120,000, is paid out of the general revenue to encourage a trade which brings into Germany from abroad as the value of sugar exported, at present prices, £8,400,000: evidently the game is not worth the candle now, but when this sum is doubled and more, as it has been in the past when sugar was selling at 22s. to 23s. then there might be some excuse for encouraging this industry which gives work and wages to such a large class of the community.

We have already seen that the loss to the manufacturer on sugar exported is £2 18s. 4d. per ton, and to the Imperial Revenue £1 8s., therefore—

800,000 Tons at £2 18s. 4d. ...	£2,333,333	loss to fabricants,
800,000 " 1 8s. 0d. ...	1,120,000	Impl. revenue.

Total National loss ... £3,453,333 on exported sugar.

A tidy sum, indeed, in order to give England cheap sugar. The writer cannot think the German Government is likely to put up with this long, especially seeing they want money.

Political Aspect.—

German population	42,750,000
Consumption, 16 pounds per head per annum ...	300,000 tons.	
Total crop (1884-5, Mr. Licht's figures) ...	1,100,000 "	
Leaving for export ...	800,000 "	
Total duty levied on beet for producing 1,000,000 tons of sugar, at £7 12s. per ton ...	£8,360,000	
Deduct drawback, £9 per ton, consisting of:—		
Duty returned on export of 800,000 tons at £7 12s. ...	£6,080,000	
Bounty paid by State on export of 800,000 tons at £1 8s. ...	1,120,800	
	7,200,000	
Receipts to Exchequer from sugar duties without deducting cost of collection, and after allowing for drawback ...	£1,120,000	

The Future.—With cereals pouring into Europe from the western countries, such as the United States, Canada, &c., and especially from the East Indies, with its horde of people willing to work for the merest pittance, it seems evident that sugar beet must be the principal industry in Germany, and in fact in the bulk of the continental countries, even if all state aid is withheld. Every beet factory turning out 3,000 tons of sugar for the campaign costs £35,000, and the shares are divided over a large proportion of the population, so that certain concessions on the part of the land-owners and cultivators, and also the assistance that science may confer upon the industry, will, the writer thinks, enable the fabricants to go on making a fair profit on the capital invested, and sugar will gradually rise to its normal paying price of £15 to £17 per ton for beet 88% sugar. The important question for the West Indians is how to keep out of insolvency while the natural settling down process is going on. It is assumed that 20 to 25 % less roots will be planted for the campaign 1884-5; this, coupled to the abandonment of a large area of sugarcane, and a probable extension of consumption, may bring about an equilibrium sooner than present prospects lead one to expect.

CONCLUSIONS.

On calmly considering the formation, there can be no doubt left in any one's mind that beetroot sugar has stolen a march on cane sugar, and that the only way by which the makers of the latter can maintain a place in the race is to further avail themselves of everything that sound mechanical and scientific research can bring to bear on their industry. Already great strides have been made in the more advanced colonies, though few will perhaps believe that the sugarcane planters have already succeeded in

recovering from the sugarcane quite as large a per centage of sugar as their opponents have done from the beet, as is shown in the following condensed table:—

BEET.	112lb.	SUGAR-CANE.	112lb.

	15'68		14'78

Advantages of Beet Sugar over Cane Sugar.—The great advantages that the Continental agriculturist and manufacturer have over the Colonial are—

1st.—A plentiful supply of willing hands to labour at moderate wages.

2nd.—Short time necessary for raw products to come to maturity.

3rd.—Favourite crops to rotate with beet and a climate suitable for growth of cereals and potatoes, feeding of stock, &c., &c.,

4th.—The roots of such a texture that they can be easily manipulated, while the residue is of considerable importance as cattle food.

5th.—Cheap fuel, with proximity to the beet and largest market in the world, and low freights.

6th.—Climate of Europe more favourable for working saccharine solutions owing to absence of ferment germs, rendering the manufacture so much more simple.

On the contrary the Colonists have to contend against—

1st. A sparse population who, in the absence of a winter and all inducement to lay by something for old age, cannot be depended upon for any continuous labour; hence necessity of importing for strangers at a great cost to prosecute the sugar industry.

2nd.—The sugar cane takes from 12 to 18 months to come to maturity, and is accompanied by a luxuriant growth of weeds. In a tropical climate much labour is required to keep these down, and also to promote the circulation of air and allow the sun to penetrate among the ripening canes.

3rd.—Absence of any crops other than plantains to rotate with canes, and as the former are perishable, and the home wants limited, they could only be grown at a loss.

4th.—The flinty texture of the sugarcane stalk and its being as yet only of value as fuel, militate against any process of manufacture that would destroy its value as such.

5th.—The nearest market in which they can purchase coals is Great Britain, and freight and charges raise their cost to 36s. and 37s. per ton before they can be delivered at furnaces. Freight home is also high.

6th.—The necessity of manufacturing the cane into sugar immediately after being cut, as immediate deterioration sets in—all saccharine running into acidity and fermentation.

ADVANTAGES OF CANE SUGAR OVER BEET SUGAR.

1st.—A large weight of cane can be grown on a given area of land, and at cheaper rate than beet roots. 18 tons of sugar cane per morgen are grown with good tillage at 12s. 6d. per ton—beet costs 13s. 1½d. per ton, and produces 10 tons per morgen.

2nd.—The sugar contained in the sugar cane is of greater purity than is found in the beet, hence less loss in purification, and the finished cane sugar is on an average 6% higher in analysis, and brings in to the manufacturer at least 2s. 6d. per cwt. more, even after allowing for the extra cost of freight from Demerara, as compared with that from North Germany to this country.

3rd.—Beet sugar must be sold as made, and is often forced on the market at unfavourable times, because it suffers heavily from increase of glucose if stored, and a heavy penalty is exacted for delivery of any but fresh-manufactured beet-crystals. In Paris, at present, beet crystals of old crop are almost unsaleable.

Weighing all these pros and cons, it is evident that the two industries are very evenly balanced, and that those of the sugarcane planters who are in a position to avail themselves of the very best appliances in manufacture might, under improved conditions of labour, look forward to times when they would hold their own against their formidable rival. One thing is evident, and that is, that strict economy must be practised in our colonies. The days when sugar at £25 to £30 could stand the enormous public expenditure which characterized some of our leading West Indian Colonies are past, and both governors and governed must be prepared to reduce taxes and expenses to the extent required for producing sugar at one-third less cost than hitherto.

Myraide, Elgis, N.B., 12th January, 1885.—The Sugar-cane.

API CULTURE.

From J. C. DOUGLAS, Esq., To the Secretary to the Government of India, dated 9th January 1885.

I have the honor to report, for your information and for record, the results of my apicultural observations during the past year.

2. I commenced the year with two stocks of the variety of *Apis indica* indigenous to Lower Bengal; one of these was a swarm I captured near my office at Allpore. As the weather

became warm, these bees built comb and they worked out artificial comb foundation specially made for them from an engraved plate from the rapidity with which they worked at the commencement of the season, I anticipated they would prove of value. Before, however, they had half filled their hives, they prepared to swarm, bred drones and queens, and I divided the two stocks into four. These did well, but I got absolutely no surplus honey. I took a few ounces but I had to feed much more.

3. This variety of *Apis indica* is kept by villagers; they do not cultivate it at all, but merely encourage the bee by inserting earthen vessels in the house walls, and they take the honey by taking all the stumps, so that the stock perishes. I have received many estimates of the quantity of honey obtained, but they differ widely and are quite unreliable. Having taken many stocks and purchased others, and having kept the bee during two seasons, I am of opinion that it is commercially valueless. Possibly 5 or 6 pounds of honey might, under exceptional circumstances, be obtained by sacrificing the bees, but this is obviously insufficient to repay cultivation. This estimate is confirmed by an account of the cultivation of *A. indica* in Ceylon,—Journal, Ceylon Branch, Royal Asiatic Society, Volume VII, part 1, No. 23. Of the stocks I had, I gave one to a station master on the East Indian Railway and one to a native gentleman; both these are in hives. Mr. Stocks, of Berhampore, has a stock, from which he recently took half a pound of honey with an extractor. Mr. Stocks being favorably situated and having the appliances will further test the value of this bee under the most favorable circumstances. This bee is not so easily handled as good-tempered Italian, but is as easily managed as the European black bee and is better tempered than the cross between the black and Italian.

4. This bee is valueless, because—(1) its stocks are too light in comb and bees; (2) it swarms too frequently, so that without trouble and much attention only, very small hives can be filled; (3) the surplus honey is very small in quantity; (4) the bees do not defend their hive against moth and other vermin, so they readily succumb to the moth, particularly during the rains.

5. Another variety found in Bhutan, building 5½ cells to the inch appears far superior to the variety found in Lower Bengal. Captain R. Fulton, B.S.C., stationed at Buxa, has kept this variety. He gave me two stocks, one of which was very weak and failed; the other I have under observation. Captain R. Fulton also gave a stock to a gentleman at Barrackpore. This variety is larger and builds larger cells than the varieties found in the plains, at Chumba, and cultivated about Mussoorie and elsewhere. I am informed its stocks are sufficiently heavy, but I have no data from which to judge of its commercial value; on this point I shall be able to give an opinion probably by the end of June next. This variety or species is, I believe, undescribed; the stock I have is exceedingly mild in disposition, the workers go out very early, and they readily use the comb of the Italian bees slightly contracting the cell by their outer edge, but they have the failing of not keeping their hive clear of vermin, particularly moth, which they suffer to live unmolested apparently on the floor-board of their hive. Should this variety prove of value, stocks can be readily obtained, but I am decidedly of opinion this variety is very inferior in value to the Italian bee, even though it may prove sufficiently valuable to warrant its cultivation.

6. The variety found cultivated at Bishahr by Mr. Minniken appears to me equal to the European hive bees in productiveness, it is closely allied to the European species, and appears somewhat large in size; whether it can be readily handled, whether it defends itself against moth and other vermin, and whether or not it swarms to such an extent as to reduce its value, can only be ascertained by observation. This variety or species is, I believe, undescribed. I am of opinion measures should be taken as early as practicable to ascertain the economic value under cultivation of this species. I have written to Mr. Minniken on the subject, and I now send two boxes with instructions for packing two stocks of these bees, which I should like to receive as early as practicable to admit of their being observed during the coming season, provided you are pleased to obtain them for me.

7. As to the possibility of cultivating the Italian bee, I am now quite convinced it can most certainly be cultivated here. I brought out five queens, of which I saved two, and in 1883 these two filled their hives, although they had at first but a few hundred bees; I had nursed these into strong stocks, when one of the queens died; I had no drones, and the rains prevented drone breeding. I had therefore only one stock left. I wrote for four queens, and these were sent by Sir G. Birdwood, but only two arrived alive. One of these became diseased, and I had to destroy her. I again sent for four stocks direct from Milan; of these I saved two queens, which are doing well. I bred a queen, the first bred in India; this queen is doing very well; her stock is very vigorous. I was obliged to remove it from the apiary as it attacked another stock, and robbed it of all its stores. I have now five queens with bees; the stocks are still weak, but I have no doubt whatever I shall be able to distribute during the coming season queens and bees to perhaps a dozen persons who are prepared to receive them. One of the queens was born in 1882; she is now 2½ years old at least, and has been in India more than two years; she has furnished bees and brood for all the other queens, and to keep up diseased stocks, and last year I took 15 lbs of excellent honey from her stock, which, as it was kept in Park-street, Calcutta, had very little opportunity of furnishing a rich harvest. I found the bees did exceedingly well; they kept their hives clear of wax, moth and other vermin. I found two deaths—head moths in one hive, evidently destroyed by bees. I find the bees can get pollen all the year round; it was feared they might not get anything in December and January, but they get almost too much pollen during these months; they are getting honey now.

8. The largest yield per stock I have had reported for *Apis indica* is 80 lbs. of honey; this is reported by Mr. Seymour

of Mussoorie. This gentleman has kept bees for several years in Australia, and his testimony is therefore of considerable value. He thinks bee-keeping with *Apis indica* as found about Mussoorie very inferior economically to the culture of *A. mellifica* in Australia. Setting aside such figures as 500 and 600 lbs. per stock in America, G. M. Doolittle, an apiarist of great experience, considers 50 lbs. of comb honey or 75 lbs. of extracted honey an average crop per stock. Thirty one Canadian bee-keepers had 1,484 stocks in the spring of 1884; increased to 2,669 stocks during the year, they took 37,250 lbs. of comb honey and 59,845 lbs. of extracted honey. I think one pound of comb honey equal to quite 1½ lbs. of extracted, and so estimated, the yield as above was equal to an average of 80 lbs. of extracted honey and an increase of 90 per cent in stocks of bees. The crop of the year was considered scarcely up to the average. The severe and long American and European winters render apiculture more precarious than in the plains of India, or even in the hills. The great superiority of *A. mellifica* over *A. indica* and the importance of acclimatizing the former is apparent; the Bishahr bee might prove as productive as or more than *A. mellifica*.

9. I could distribute stocks last year had I wished, the one queen would have supplied bees, queens and drones, but I preferred to import other queens rather than breed in and in. The journey from Europe is very injurious to the queens; even those which appear to arrive in good health are commonly found ultimately to have suffered in their laying powers, or to have become diseased. Knowledge of this fact induced me to import a number of queens in the hope of saving few, and the ignoring of this has caused the failure of all previous attempts to induce the European bee into India.

10. During the year I have issued a number of hives and other appliances to persons anxious to take up apiculture in different parts of India; these persons are practicing and learning on *Apis indica*. The issue of Italian bees during the coming season will, I have no doubt, confirm these persons in their resolves, and spread the practice to many others. The Italian bees will be issued to bee-keepers in British Burmah, Assam, Orissa, Bengal Proper, Mussoorie and Dehra, Bhootan, and elsewhere.

11. As to the natural history of Indian bees of the genus *Apis* very little is known: several varieties of *A. indica* and *dorseti*, and *A. florea* have been described, but there is much confusion in naming them: in most cases the descriptions are incomplete, not including the descriptions of drone, queen, and comb; life history has not been studied, and some Indian honey bees have not been described at all, being quite unknown to European naturalists. In 1862, Dr. Gerstaecker of Berlin discussed the classification of Indian honey bees in a paper read to the "Wander Versammlung Deutscher Bienenwirthe," and pointed out the confusion that existed in nomenclature and excellent grounds for a classification, so far as the available knowledge admitted. Since the decease of the late Mr. F. Smith, I am informed there is no member of the British Museum staff specially qualified by knowledge of this genus of insects.

12. In my little Handbook of Bee keeping for India, I described a typical *A. indica* and omitted all mention of the varieties and their synonymous names; I am about to carefully examine the collection. I have, and I hope to obtain, other specimens. Specimens, particularly, if including the drone, queen, and a small piece of comb, would be of great service, I have no doubt whatever. I shall be able to add considerably to the existing knowledge of Indian honey bees and their life history, as well as discover some of economic value in both the Bhutan and Bishahr bees; it appears probable insects of economic value have already been discovered. It remains to decide by observation how these compare severally with the Italian bee now rendered available.

13. As I am about to examine, measure, and describe all the Indian honey bees of which I can obtain specimens, and also to endeavour to discover their affinities and the bearings of these on the origin of the European hive bee, which probably originated in Asia, and as I may not only be able to indicate the best variety and best mode of cultivating it for the benefit of the natives of India, but I may also obtain information of economic and scientific importance to European and American apiculture, I beg that any spare specimens of the number collected by Dr. G. Bidle may be sent to me.

Instruction for transferring and packing Bees in portable Hives.

Smoke the bees slightly, spray them with thin syrup unless they have honey accessible in their combs; then with smoke, by shaking and brushing the bees from the combs, remove the combs one at a time. Fit the combs into the frames against the top bar, cutting the top of the comb straight, if necessary, and filling up the frames with pieces of comb, if available. The wirefixers are for holding the comb in the frames while tying it in. Tie the comb in the frames by stout twine at every two inches and vertically and horizontally. Very white new combs should be rejected, very thick heavy combs containing much honey and sealed may be pared with a knife to one inch. The brood combs, if any, should be placed in the centre frames. If there be much honey in the combs, other food may not be necessary, but full combs travel badly, and food may be given by mixing honey and crushed white sugar to a stiff paste and filling the foodbox with it. The water bottle should be filled, and so corked that the water does not come out unless the bottle be shaken.

2. The combs having been transferred, shake or brush the remaining bees into the box; close carefully with cloth, or by other means, the ventilators of the box, cover the top and open the door; place the portable hive in the place of the old hive. The portable hive with its entrance, as far as practicable, with some place as the entrance of the old hive, should be left till evening; after dark, when the bees are all in, the door should be closed, the ventilators opened, and the box despatched.

3. If the weather be very cold, the side ventilators may be partly covered, but otherwise they should be left quite uncovered. One brood comb at least should be inserted, if possible, even if from another stock, as the presence of brood prevents absconding.

4. If detained on the road, the bees may be allowed to fly, the door being opened, and closed again after dark. Whenever the door is opened, the side ventilators must be completely closed.

Unless the boxes are to be closed longer than a week, it would not be desirable to open the hive boxes *en route*, and then only if some one is present who could hive the bees if they swarmed out.

5. It will be found convenient in transferring to remove all the frames from the box and put the lid on; as each comb is out out of the old hive, brush the bees from it into the box and put on the cover; if the principal cluster be gently lifted and shaken into the box, there will be no fear of the queen having been left behind.

See also "Driving" and "Transferring" in the Handbook of Bee-keeping for India.

6. The boxes contain a veil, smoker, spray diffuser, and on dozen comb fixers; the articles should be retained excepting the latter, which may, if necessary, be left in the comb, but should, if practicable, be removed.

THE TRANSPORT OF TIMBER.

THE American sawmills, established long before anything of a similar kind in England, showed that cheap transport is the basis of any profitable wood industry. The present perfection of mechanical appliances in the lumber domain began with the splendid water-carriage-ways given of the great rivers of the United States and Canada. These, though accompanied by timber jams, far out-rival any railroad facilities of transport.

The ease with which logs may be thus taken from the forest to the sawmill, and afterwards to the seaboard for exportation, is the foundation of the great Canadian timber trade. Dull times appear to be putting more sprags in its chariot-wheels of progress. But this shutting down the vacuum breaks will be only the greatest national blessing if, as *Forest and Stream* says, the Canadian and United States Legislatures at last open their eyes to the folly of alienating public forests for a dollar and a quarter an acre, which it will be impossible to replace ten years hence at fifty dollars an acre. But the British landowner is handicapped by his only available carriers, the great railway companies, and is at present in a sorry plight. Notices of bills for the purpose of increasing rates, specially terminals, have been lodged by these great corporations, which, if carried, will render the transport of home-grown timber unremunerative. If the prospects of successful improvements of estates by forestal enterprise are not to vanish as chimeras, instant decided action must be taken.—*Forestry*.

THE AUSTRALIAN BOTTLE-TREE.

THIS oddity of the Australian woods may not be unfamiliar to many British readers. For the frequency of inter-travel betwixt the youngest of our southern colonies, Queensland, the dwelling-place of the bottle tree, is amongst the noted features of British home life. This tree—*Stercularia rupestris*, (Benth); *Brachychiton Delabechii*, (F. Mueller)—belongs to a peculiar order, the *Sterculariaceae*, confined to the tropics, noted for its unique forms, such as that of the baobab tree, but possessing as well the chocolate and cocoa tree. There are several species of this genus in Australia, only one of which is known to extend beyond the island continent. None of these have as yet proved economically useful. But in Asia several members of the order yield useful furniture wood; one yields material for canoe-building, another supplies good fibre. The representative *Stercularia* of the Amazon district rank in height and magnificence as the monarchs of the forest.—*Forestry*.

THE WEIGHT OF AN AXE.

I WELL remember my first axe, and my early experience with it. It weighed 4½ lbs., being the heaviest one I could find at the time. I was fresh from school—fresh from a class in natural philosophy, one of my favourite studies.

I knew all about inertia, and had learned something of the force of gravity and the laws of falling bodies; had rightly guessed that chopping wood might be hard work, and determined that my knowledge of physics should help me out.

I would have a heavy axe, a long handle—would move slowly, and take strokes that would count when they fell. My axe-handle was 34 inches in length, the longest one in the store. I had hired a tough little French Canadian, weighing about 120 lbs., to help me at this work. When he came, he brought an axe—a mere toy, I call it. I think it weighed 2½ lbs., with a handle only 26 inches long. I told him I had a fair-size job for him, and thought it would pay him to buy a full-grown axe. He smiled, and said he guessed he would do. I tried to explain to him the beauties of a heavy axe,

and the wonderful advantage of a long handle. But it was all in vain; I was only wasting time, for he could not understand it.

"Poor fellow," I thought, "he knows nothing of the beautiful science of physics. It is too bad that he should thus waste his strength through ignorance, and be unwilling to listen to the voice of wisdom."

We went to the wood-lot and began work. I had decided that we would work separately during the first day or two, in order that I might show him what I could do.

As I began to swing my axe, I felt proud of its ponderous blows that rang through the woods, and rather pitied the poor fellow who was drumming away with his little axe, taking about two blows to my one.

Presently I had to stop to rest, and then again, and still again. But Joe, my man, kept pecking away quietly, steadily, and easily.

Every few minutes I would stop to take breath; but Joe seemed perfectly able to do all necessary breathing without stopping his work for the purpose.

When night came, we piled up our wood and measured it. Joe's pile measured 1½ cords; mine only ½ of a cord.

During the early part of the day, I had planned giving Joe another lesson in the evening, to see if I could not make him understand the elementary principles of wood-cutting, and the philosophical requirements of an axe.

But when night came I decided that perhaps it would be as well to let him go on in ignorance, and thereafter remained silent on the subject.

The next day I felt lame, and stayed at home. Joe put up his cord and a half as usual.

When I went to the woods again, Joe and I worked together. Not many days passed before I found an excuse for buying a lighter axe and a shorter handle. And every axe and handle that I have bought since then, has been lighter and shorter than its predecessor.

Whenever I use an axe now, I select one very much like Joe's, both in weight and length of handle. I can use this without getting all out of breath, and can hit twice in the same place. The result is, I can do more and better work, and save a vast amount of strength.

I write this as a word of caution to the inexperienced wood-chopper, when about to purchase an axe.—H. L. C., in *Albany Cultivator*.

A SKILFUL SURGICAL OPERATION.

THE American Ambassador at Vienna, Mr. Kasson, has lately forwarded to his Government an interesting account of a remarkable surgical operation lately performed by Professor Billroth, of Vienna, which, wonderful to tell, consisted in the removal of a portion of the human stomach, involving nearly one-third of the organ—and, strange to say, the patient recovered—the only successful operation of the kind ever performed. The disease for which this operation was performed was cancer of the stomach, attended with the following symptoms:—The appetite is quite poor. There is a peculiar indescribable distress in the stomach, a feeling that has been described as a faint "all gone" sensation; a sticky slime collects about the teeth, especially in the morning, accompanied by an unpleasant taste. Food fails to satisfy this peculiar faint sensation; but, on the contrary, it appears to aggravate the feeling. The eyes are sunken, tinged with yellow; the hands and feet become cold and sticky—a cold perspiration. The sufferers feel tired all the time, and sleep does not seem to give rest. After a time the patient becomes nervous and irritable, gloomy, his mind filled with evil forebodings. When rising suddenly from a recumbent position there is a dizziness, a whistling sensation, and he is obliged to grasp something firm to keep from falling. The bowels costive, the skin dry and hot at times; the blood becoming thick and stagnant, and does not circulate properly. After a time the patient spits up food soon after eating, sometimes in a sour and fermented condition, sometimes sweetish to the taste. Often-times there is a palpitation of the heart, and the patient fears he may have heart disease. Towards the last the patient is unable to retain any food whatever, as the opening in the intestines becomes closed, or nearly so. Although this disease is indeed alarming, sufferers with the above-named symptoms should not feel nervous, for nine hundred and ninety-nine cases out of a thousand have no cancer, but simply dyspepsia, a disease easily removed if treated in a proper manner. The safest and best remedy for the disease is Seigel's Curative Syrup, a vegetable preparation sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White (Limited), 17, Farringdon-road, London, E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

ST. MARK-STREET, PETERBOROUGH.

November 20th, 1891.

Sir,—It gives me great pleasure to inform you of the benefit I have received from Seigel's Syrup. I have been troubled for years with dyspepsia; but after a few doses of the Syrup, I found relief, and after taking two bottles of it I feel quite cured.

I am, Sir, yours truly,

Mr. A. J. WHITE.

WILLIAM BRENT.

September 8th, 1893.

Dear Sir,—I find the sale of Seigel's Syrup steadily increasing. All who have tried it speak very highly of its medicinal virtues,

INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA :—SATURDAY, MAY 16, 1885.

[No. 20.

Grop and Weather Report.

[FOR THE WEEK ENDING 6TH MAY 1885.]

General Remarks.—Slight rain has fallen in a few districts in Madras and Mysore. In Bombay, some rain is reported from parts of Dharwar, Belgaum and Kaladgi, and in the Punjab from the Umritsur, Lahore, Rawul Pindes, Shabpore, and Peshawar districts. In Bengal rain has fallen generally throughout the Province, and has done much good to the standing crops. In Assam heavy rain fell in the four reporting districts of the Brahmaputra Valley and in Cachar.

Agricultural prospects remain unchanged in Madras, and continue uncertain in Mysore. In Coorg the growing crops are doing well, and the prospects of the season are good.

The *rabi* harvest is nearly over in Bombay and the North-Western Provinces and Oudh; in the latter an average outturn is expected. Preparations for the *kharif* are going on. In the Punjab the *rabi* harvest continues in active progress, and *kharif* sowings have commenced. Threshing and winnowing of the *rabi*, and *kharif* preparations, are in progress in the Central Provinces.

In the Berars, the Nizam's Territories, and in the Central India and Rajpootana States, harvest operations continue, and prospects are generally good.

In Bengal the recent rain has facilitated agricultural operations and improved the prospects of the standing crops. Ploughing and sowing continue. More rain is wanted generally throughout the Province.

In Assam ploughing and sowing are in hand, prospects are good.

Cholera is chiefly prevalent in parts of Bombay, Bengal, and the Central Provinces, but public health is generally good.

Prices are generally steady, except in Bengal, where the price of rice has on the whole risen.

Madras.—General prospects fair, except in parts of Bellary and Anantapur.

Bombay.—Slight rain in parts of Dharwar, Belgaum, and Kaladgi. *Rabi* harvest completed in all districts, except Skikarpore and Upper Sind Frontier: ground being prepared for *kharif* crops in parts of eight districts. Scarcity of fodder and drinking-water continues in parts of several talukas of Dharwar and Belgaum. Fever and cattle-disease in parts of 9, cholera in parts of 15, and small-pox in parts of 18 districts.

Bengal.—There has been rain in every district of Bengal Proper, and in about half a dozen districts in other parts of the province. It has much facilitated agricultural operations, and improved the prospects of standing crops. More rain is, however, generally wanted all over the province. Ploughing of lands and sowing of early paddy is going on. Price of rice has, on the whole, risen. Cholera and small-pox prevail in many districts.

N.-W. Provinces and Oudh.—Weather seasonable. Harvesting nearly over; an average outturn expected. Markets well supplied and prices steady. Cases of cholera and small-pox reported from some districts.

Punjab.—Rain in Umritsur, Lahore, Rawul Pindes, Shabpore, and Peshawar districts. A few cases of cholera still in the Lahore and Umballa districts, and slight fever in Peshawar; health otherwise good. Prices almost stationary.

Central Provinces.—The weather has been clear and hot, but is to-day again cloudy and stormy. Prospects remain unchanged, and prices steady. Cholera is said to be increasing in Hoshungabad, Khandwa, and Raipore.

British Burmah.—Cholera severe in town of Pegu, slight in Akyab, Bassein, and Toungoo districts. Weather hot.

Assam.—State and prospects of crops as last week. Public health fair.

Mysore and Coorg.—Growing crops in good condition. Prices of food-grains stationary. Prospects of season and public health good.

Berar and Hyderabad.—Weather hot, with occasional dust-storms. Ploughing operations going on. General health fair, except in Ashtnagar and Shahabad talukas, where cholera has appeared.

Central India States.—No more cholera in Residency. Weather warmer. Prices stationary. Cholera reported from Mhow; sudden outbreak amongst natives, but very few fresh cases; otherwise health good.

Rajpootana.—Weather seasonable. Prices stationary. Health good.

Nepal, April 30.—Weather cooler and more seasonable. Prospects moderate.

Letters to the Editor.

HOW TO KEEP OFF RATS FROM PLANTS.

I.

TO THE EDITOR.

SIR,—With regard to the method suggested by Baboo Hem Chundra Datta in your issue of the 9th instant, for getting rid of rats, will the gentleman or yourself oblige a large number of enquirers by giving the Bengali name of cowhage (*Mucuna pruriens*)?

AN ENQUIRER.

Midnapore, May 12, 1885.

II.

TO THE EDITOR.

SIR,—In reply to the letter of your correspondent "Enquirer," in which he asks to know the Bengali name of cowhage (*Mucuna pruriens*), I beg to state that it is generally known to natives by the name of *al-koochee* or *bandanria salm*. In the Mahratti language it is called *khajree koori*, and was well known to Mr. W. G. Betham, at one time an Assistant Conservator of Forests, Dharwar, for its beneficial effects in keeping rats and vermin from the roots of trees.

HEM CHUNDRA DATTA.

Raghoonath Chatterji's street }
Malakar's Cottage, May 14, 1885. }

TEA AND HOPS IN THE KULU VALLEY.

TO THE EDITOR.

SIR,—In your issue of the 4th of April, I note an article anent the growth of tea and hops in the Kulu Valley. The writer says that cultivation does not seem to be very successful.

He apparently has not had an opportunity of forming an opinion. No one who saw the bushes at Dhobie, Raisou, or Aramgarh, would doubt its success.

In stating it as his opinion that hops will not grow under 5,000 elevation, he appears ignorant of the fact that the famous Golding hops of East Kent, and the Bines of Farnham are grown at a much lower elevation. In Canada and Cashmere, they are grown successfully below that height.

The adverse inferences your correspondent draws of the growth of tea, and hops, may be derived from the peculiarities of some particular locality, but are erroneous as applied to the whole of the Kulu Valley.

ÆGIS.

Editorial Notes.

THE Government of Madras have, we learn, accepted the suggestions of the Chief Engineer for Irrigation, that the Collector should arrange to take charge of all tanks in the Madras district, and submit revised proposals for watching the bank of the Mylapore tank when full. He will, of course, seek for the advice of the Public Works officers when any work requiring professional advice has to be executed.

WE learn from a gentleman who has but recently returned from a district town that cattle are at starvation point in many parts of the Toomkoor and Shemograh districts. There has been no rain, and the pasturage having all been burnt off by the excessive heat, cattle subsist on the leaves of trees, and those which belong to the ryots living in the vicinity of the high road manage to keep alive by feeding on the ripe figs which fall in abundance from the avenue trees of the variety planted on the road. Even water is difficult to be had; the small tanks have dried up long ago, and the bigger ones, which have been traditionally said to never have been known dry, are fast becoming muddy deposits.

THERE were seventy-eight collieries at work in Bengal at the end of the year 1883, the output from which was reported as 1,200,937 tons, and two in the Central Provinces (Mohpani and Warrora), from which 115,019 tons were raised. This output compares very favourably with the average of previous years, but the next return ought to show a still larger quantity, as no mention is made of the new mines at present at work in Assam or of those which have been commenced in the State of Rewah. The number of persons employed in the mines in both Bengal and the Central Provinces is given as 23,172; but there is some doubt about this figure, as some of the returns are defective.

THE railway coolies on board the *Jumna* must have been considerably puzzled. They were sent to Suakin to help to make the railway to Berber. Then, as the railway was abandoned, they returned to Bombay via Aden. At Aden the *Jumna* was countermanded, and ordered to return to Suakin, where, we are told, the coolies will be employed in making huts for the garrison. We suppose the explanation may be found in the urgency with which transport is now required. The *Jumna* is wanted for a more important cargo than coolies, and they will have to remain at Suakin, making huts, until in more leisurely times an opportunity occurs of bringing them back to Bombay.

FROM correspondence courteously placed at our disposal, it appears that the Madras Government have experienced some difficulty in controlling the illicit manufacture of liquor by Khonds and Urya Sundis in the Pedda Kinnedi, Chinna Kinnedi, and Goomsur Maliahs. In all 28 abkari licenses were issued in the first named maliah during 1884, and the total amount levied was Rs. 112, each license being charged at Rs. 4. The licensing system has been introduced into the other maliahs, but with small success.

THE Government are therefore of opinion that the orders forbidding distillation by Urya sundis, should be strictly maintained in force. From a revenue or social point of view, the so called illicit distillation is considered a matter of trifling importance, and must be tolerated if licensees other than Urya Sundis can not be obtained.

MR. W. WILSON, the Director of Revenue Settlement and Agriculture, has addressed a letter to the Government of Madras, on the subject of fibre, and has forwarded some samples prepared at the Saidapet farm under the direction of the Agricultural Reporter to Government from the Manilla hemp-plantain (*Musa textilis*), and from the common plantain tree (*Musa paradisiaca*), and has suggested that they be sent to the Secretary of State for India for valuation in the London market. He adds that he would have asked some of the local mercantile firms to have this done, had it not been that some time ago he was informed by one of the leading firms in Madras, that samples sent for valuation were valueless unless they were of considerable bulk—say, two or three tons. As, however, the Government Reporter could not conveniently supply a sample

of this bulk, he thought a London broker would have no difficulty in appraising the value of fibre of the same standard of fineness by the samples he now sent.

A Ceylon contemporary hears that there is every prospect of a powerful association, to be called the Kelani Valley Planters' Association, being started very shortly, to include not only estates actually in the valley, but also those in Western Dolosbagie, if they will consent to join, which is very probable. A general meeting will be called early in May at some convenient spot, probably the Yatiyantota Rest House, at which all interested in the movement should be present to inaugurate the movement which is already assured of success by the support of all the most influential men in the district. We earnestly trust that the efforts of those who are striving to launch the undertaking will be successful, and that the Association may have a long career of prosperity before it. The present Association, too, stands in need of such help as the affiliation of another strong and powerful body will give it.

WE learn that Mr. P. Bosworth Smith has been appointed by the Secretary of State, on the recommendation of Professor Chandler Roberts, to the newly created post of Government Mineralogist in the Madras Presidency. The appointment will be for three years certain, on a salary of Rs. 500 per mensem, commencing from the date of arrival in India, with a travelling allowance of Rs. 250 per mensem, and a first class passage to Madras, but not a return passage. Mr. Bosworth Smith arrived in Madras by the steamer *Peshawar* on the 26th April. The duty of the new official will be to create, in connection with the Central Museum at Madras, a perfect index to the mineral wealth of the Presidency. The instructions issued to him are that he should, in the first place, go carefully through the collection of minerals now in the Museum, and subsequently travel to Ootacamund to confer with Dr. Bidie and such other officers as the Government may instruct him to communicate with, prior to engaging in a mineralogical survey of the Presidency, on which it is proposed that he should be employed.

A CONTEMPORARY, referring to the Presidency of Madras, says that it may be "benighted" in some things, but the Southern Presidency frequently sets the other divisions of the empire an example in the direction of administrative activity. Madras has long had an Agricultural Department, which has done and is doing much good work in spite of occasional mistakes, such as the importation of expensive and unnecessary seed drills, noticed in last year's Madras Administration Report; it has also an active Archaeological Branch; and among other things, it is advanced in the important matter of village sanitation. We noticed the other day a scheme which has originated at Madras for distributing cheap medicines, especially quinine, amongst the poor population, and inducing the people to adopt the remedies placed at their disposal. Now, we notice another suggestion, which, if carried out, might not inconceivably have even a wider effect towards reducing the fever mortality—prevention being admittedly better than cure—than the utmost success to which the medical project could attain. The idea is that itinerant scavenging gangs of some half-dozen men each, under a jemadar, should be formed to go from village to village and thoroughly cleanse them, removing accumulated filth, digging pits in convenient places for the deposit of rubbish, levelling the streets, digging side drains, &c. It is calculated that every such gang would be able to give an annual cleansing to some 50 villages, and that twelve gangs, to cleanse 600 villages a year, would cost about Rs. 7,500, or Rs. 12 per village cleansed. Another suggestion is that village Mooniffs should be empowered to levy small fines in punishment for nuisances committed in cleansed villages.

DR. HENRY TRIMEN, of the Royal Botanical Gardens, Peradeniya, writes as follows to the *Ceylon Observer*, on the subject of Coka leaves from Ceylon (valued at 13s. per lb.):—

As it has been stated that the few samples of coka hitherto sent from the East were of inferior quality, I have lately sent home a

small quantity plucked in the gardens here, with the view of ascertaining the real value of the Ceylon leaf.

A pound of fresh mature leaves was gathered; they were dried carefully in a current of dry air under a verandah, the process being finished off in the sun. This was in the steadily dry weather of last February. The leaves lost half their weight in drying. When finished (in 10 or 11 days), the samples was packed in a tin box and sent by post to Mr. T. Christy, of Fenchurch-street, for report. He has kindly sent the following information, which will be read with interest:—"You will be pleased to hear that Mr. Dillworth Howard has tested the coca leaves, and finds they contain 22 per cent of pure cocaine, which is considered a very fair percentage. At present the cocaine of Merck is selling here at 22s. 6d. the gramme; therefore, as a gramme of hydrochlorate of cocaine is produced from a lb. of leaves, this would make the leaves worth in the market at the present time 13s., and leave a large margin for the maker."

This report seems to show satisfactorily that the leaves grown here yield a fair amount of alkaloid, and that prepared in dry weather without any special precautions, they will travel home in good condition. I, therefore, lose no time in making Mr. Christy's information public.

.

A CONTEMPORARY says:—Famine seems to be the order of the day. While the Government and the public are co-operating together to tide over the crisis in parts of the Beerbhoom district, news comes to us from Bankoora that "serious distress" has broken out in the Sonamuki thanna, in the Bankoora district. We publish the letter of the Commissioner:—

"With this office No. 46 dated 4th September 1884, Mr. Wilson submitted a report on threatened scarcity in parts of Bankoora. The scarcity was at that time rather apprehended than actually felt, and the Collector had at his disposal sufficient funds from various sources to meet all necessities, and no aid was asked from Government."

"From the annexed sketch map it will be seen that serious distress is confined to a tract in the Sonamuki thanna. Aid of an indirect kind is, however, required in a tract stretching to Indas and Kotulpore.

"The Collector's proposals are judicious, and I have already verbally signified my approval of them to him when at Bankoora. It will be seen that he estimates that it will be necessary to expend Rs. 12,000 on charitable relief. Of this he has already Rs. 4,000, and hopes to get Rs. 1,000 more, so that an additional sum of Rs. 7,000 is wanted. I hope Government will be able to grant the whole, or a large portion, of this sum between this and September next.

"We are bound to say that the Government has not given a generous response. The sum of seven thousand rupees required by the local authorities has been granted, but in monthly instalments of one thousand rupees, probably in the hope (as evil-minded people may be disposed to think) that the whole of the amount may not be wanted. This is scarcely generous of the Government, especially after the absorption of the Famine Insurance Fund."

.

THE Conservator, Southern Division, recently submitted proposals with estimates for extending the teak plantations at Nilambur in the Madras Presidency, by planting 100 acres annually for ten years. The plantations were to be treated as coppices with standards, the trees to be coppiced being teak, and the standards mahogany, planted 50 feet apart. The total cost of formation and maintenance for 10 years per 100 acres has been estimated at Rs. 7,800, or Rs. 10,656 with interest at 4 per cent to the end of the eleventh year, when a first return of Rs. 25,000 is anticipated. The produce of the plantations is to be devoted to the supply of teak poles for which the demand is very large, but possible objections on the part of the lessor will be fully met by having sixty saplings per acre to mature into forest trees. It appeared, however, to the Government to be doubtful whether the Government will not have to be paid under the terms of the lease. The Board of Revenue will call for a report as to the grounds on which payment of stump fee for saplings has been hitherto refused, and as to the financial effect on the calculations of payment being made for them. Upon receipt of this information, the Government will be in a position to decide upon the matter.

THE testing of seeds for planting or sowing, to determine their germinating quality, is a matter of no little importance to the farmer or gardener. A writer in the *North British Agriculturist* gives a simple method of doing this, which he pronounces far superior to moist flannel or earth. He takes two flower-pot saucers, one smaller than the other, say one 10 and the other 12 inches in diameter, and lays his seeds to be tested in the bottom of the smaller one. This may be divided off by lines and several different kinds of seed placed in it at the same time, 100 seeds of each kind being placed in each division; the larger saucer is half-filled with water and the smaller one, with a pane of glass over it, is placed in it. They should be kept in a warm place where an even temperature is maintained. The water in the outer saucer will penetrate the loose porous material of the inner one, supplying all necessary moisture to the seeds, while the glass over the top will prevent evaporation, and maintain a moist warm atmosphere about the seeds. The number in each 100 which sprout indicates the percentage of seeds which can be depended upon to grow. As light is unfavorable to germination, it is well to paint the glass, or cover it with paper. The condition of the seeds can be ascertained at any time by simply lifting the glass, and no care is required beyond keeping the larger saucer supplied with water.

.

A CONTEMPORARY, commenting upon the recent exhibition of ploughs at Ootacamund, says:—The fair amount of success that attended the exhibition of ploughs and the ploughing matches held at Ootacamund some months back under the auspices of the popular Collector of the district, induced the authorities to notify that another exhibition and a few matches would come off in April or May. It appears, however, that the notice issued for the information of the ryots and the badagas, did not meet with a favourable reception. Few if any of them applied to exhibit their ploughs and other agricultural implements, and it has been decided to put off the show for a little time. It is to be regretted that these occasional shows cannot be held in the district in accordance with the arrangements made by the revenue authorities. We have ample evidence in the reports issued by the Agricultural Department, that these exhibitions and ploughing matches have done some good, and that many of the better classes of ryots have begun to use cheap and improved descriptions of ploughs. The ploughing matches in the Nilgiri district may, as time passes, induce the Badagas to push forward agricultural work and grow barley and other descriptions of cereals which were once available in the district, but have now almost ceased to receive attention, and consumers are consequently dependent upon importers for the article. A small exhibition of implements, especially at the time when the Government is on the hills, and when the whole official world is up "in the clouds," may be productive of good results, and induce the Badagas to make improvements in the cultivation of the soil which, from all accounts, is gradually and steadily deteriorating.

.

THE following is the result of the last examination of students at the Royal College of Agriculture, Cirencester. It will be observed that the names of two Bengali students occur as having gained diplomas, while one of them is 'honorably mentioned':—

DIPLOMA (Maximum marks, 2100; qualifying marks, 1400)—Cecil George Fraser Thonger, Lords, Wood Road, Harborne, Birmingham, 1946; Bhupal Chandra Basu, Bengal Government scholar, 1905; Charles Albert Curry, R. malho, Mulgrave Road, Sutton, Surrey, 1721; Atul Krishna Roy, Bengal Government scholar, 1693; Harry Gilbert Henderson, Dunholme, The Park, Obeltenham, 1681; Jas. Mitchell, Gibb, Vere, Jamaica, 1871.

DUKE GOLD MEDAL.—Cecil George Fraser Thonger.

SCHOLARSHIPS.—(Open to the whole college. Maximum marks, 2900; qualifying marks, 2500)—First scholarship, Alfred Denis Faber, Barrow Lodge, North Devon, 2874; second scholarship, William Timothy Hall, Winter's Road, Maidstone, Kent, 2810.

The following deserve honourable mention in order of merit—(qualifying marks, 2500):—Mukerji, 2747; Dickson, 2720; M'Donald, 2672; Andrews, 2660; M'Miquies, 2663; Chavasse, 2658; Cavington, 2650; Davies, 2627; Cave, 2620; Perkins, 2600; Bailey and Dudley, equals, 2583; Scott, 2581; Taverner, 2567; Rennie, 2547; Lugard, 2517.

The Principal afterwards pointed out that Mr. McDonald had gained the diploma of the Highland and Agricultural Society. Referring then to the seasonal work by the different professors, Mr. McClellan paid a very high compliment to our countryman, Professor Wallace, who had been a most successful and popular teacher in the college.

We have received a copy of the correspondence regarding a trial made of Indian wheat in South Australia, the Royal Agricultural Society of which place was supplied with a sample through the agency of Mr. H. J. Scott, who represented South Australia at the Calcutta Exhibition. The Secretary of the Society has now reported to the Government of India the results of the sowings made, which bring to light some important facts. The yield per acre is stated to have been 24 bushels, or nearly 18 maunds. This is rather an exceptional yield, when compared with that of American and Indian wheat generally. The yield per acre of the former in its native soil has been estimated at an average of 19 bushels, while that of Indian wheats, when grown on lands of average good quality, manured and irrigated, in the N.-W. Provinces, where the yield per acre is highest, was found to be at the rate of 22 bushels to the acre. The importance of the results obtained in the South Australian experiment will be better understood from the fact, as stated by Professor Custance, who made the experiment, that "the wheat was sown broadcast on about one rood of *poor unmanured ground*." The italics are ours, as we wish to draw particular attention to this point, which is of considerable importance.

If on "poor unmanured" soil the Indian wheat yields at the rate of 24 bushels per acre, which exceeds the yield of wheats grown in America and India on good, manured soil, how much greater must its yield per acre be when sown on soil of good quality? The inference we draw from this experiment of our Indian wheat in South Australia is, that the conditions for its growth and productiveness are far more favourable there than they are either in India or America. Professor Custance adds in his letter reporting the result of his experiment, that he intends making further sowings of this wheat on good soil, with the object of procuring seed for distribution next season. The result of this experiment will be looked forward to with much interest, as Indian wheats are attracting a great deal of attention just now.

We have received from the Bengal Secretariat copy of a correspondence which has passed between the local Government and the Commissioner of the Burdwan Division on the subject of the distress in Bankura. So far as the 4th September 1884, Mr. Wilson, the then Officiating Commissioner, had submitted a report to the Government of Bengal on the threatened scarcity in that district. The Collector, however, had at his disposal certain funds derived from various sources to meet impending necessities, and Government aid was not asked. Since then assistance was given principally in the shape of grants from the Road Cess for village roads, which gave work to those in the distressed tracts. People who were too weak to work were supported by charitable relief. In February last Mr. Beames held an interview with Mr. Taylor to concert measures necessary for the future. In accordance with the instructions given by the Commissioner, the Collector instituted enquiries and embodied their result in a letter to him, dated the 24th of the same month. The information contained in it being insufficient, a second letter was called for, in which the Collector states "that the number of persons requiring gratuitous relief in the jurisdiction of the Sonamukhi and the Gangajalghati thannas is 1,275; of this number 278 are children, 689 men, and 308 women. Most of the men and more than half of the women are incapable of physical labour by reason either of old age or disease, the rest of the women being *gurdanushen*. The cost of feeding this number, allowing two pice per diem for each adult, whether male or female, and one pice for each child, would be about Rs. 2,000 per month," as the next rice crop will not make its appearance in the market till the end of September, a sum of Rs. 12,000 will be required between April and September. The Collector has in hand Rs. 4,000 raised by private subscriptions, and he expects a further sum of Rs. 1,000 from the same source. The Government have therefore been asked to contribute the balance, Rs. 7,000. The Magistrate proposes to send for paddy from Midnapore

where it is cheap. This will not only give relief to a large number of cartmen who are without work, but the women who are prevented from appearing in public might be induced to husk the paddy at their houses, at the usual rate of two seers of rice for every 20 seers husked, and thus be relieved of the necessity of looking to charity for support. The Collector recommends that the rice be distributed raw, as it will ultimately effect a saving of Rs. 900 a month, and no useful purpose would be served by issuing it cooked. These proposals of Mr. Taylor were accepted by Mr. Beames, and recommended to the favourable consideration of Government. The Lieutenant-Governor, while approving of the suggestion, thinks it best not to grant the entire sum of Rs. 7,000 at once, "but he will place a sum of Rs. 1,000 each month at the Collector's disposal for that purpose. Should, however, a larger share of the Rs. 1,000 be wanted in any month, this requisite amount will be granted on due representation being made to Government."

A good deal has lately been written on the subject of tea fermentation, upon which there is much diversity of opinion. The following letter addressed (by an expert evidently) to the *Ceylon Observer*, throws some valuable light on the subject:—

There has been much dispute upon whether "oxidization" should not be substituted for the term we usually use as "fermentation" in the manufacture of tea. Under any circumstances I should say that ferments would be discovered as present in this process, and it is furthermore undoubtedly the first stage towards decay, unless we may consider decay as beginning with the wither. There is a great deal in the term "decay," and this appears to be more implied by the expression "ferment" than by oxidization, although some are very much inclined to believe the change in our tea is as much owing to the former as the latter. Whenever mere water, saying nothing of decomposing compounds, such as tea after rolling, has first been boiled to destroy animal and vegetable life, and then exposed to the normal atmosphere, it has always succeeded in killing it in a very short time with life, and, as far as I have studied the subject, this is even the case with tobacco water, a very certain destroyer of insect, and I may say all vegetable matter.

Inorganic compounds never of themselves ferment as far as the correct meaning of that word applies. Chemical change may take place, heat may be produced, and oxygen very frequently comes into active play. With organic compounds oxidization of course takes place, but this most probably in conjunction with ferments. I should think the germs of fermentation are usually first contracted during the wither and develop themselves after the roll. Fermentation and decay of course mean the absorption of a deal of oxygen from the air, and is very much affected by the slight addition of water. Excessively fermented tea becomes sour, indicating I suppose the change of some of the sugar, starch, or tannin into active acid. The production of acetic acid has, however, recently been called oxidization and not fermentation.

Fermentation correctly, I conclude, means the presence of another influence acting upon the tea, or whatever the substance be, as yeast upon beer, or gluten upon sugar. In organic properties, however, it must be very difficult to determine how far the germs of the atmosphere act upon our decomposing tea, consisting as it does of all the necessary elements to produce fermentation quite as much as oxidization, both gluten and sugar being present.

It would be very interesting if some one who can treat the subject more fully would take it up, for it is many years since I studied these subjects.

A few weeks back we noticed the new steam tea rollers recently brought out by Mr. Jackson to Ceylon. The following letter, addressed to the *Ceylon Times* by a correspondent, gives the result obtained from experiments made with Sirocco and Jackson's hand-roller, which may prove interesting to many of our readers:—

I noted in your issue of the 28th ultimo a letter from Mr. C. A. Hay, of Blackwater, Nawalapitiya, on tea drying by siroccos. I note he got 30½ lb. made tea per hour from No. 710 old style sirocco, with charge of 9½ lb. fermented leaf per tray. I have just made a careful experiment with mine, No. 637, old style, with a charge of 7½ lb. fermented leaf and a mean temperature of 283°. I got 34 lb. made tea per hour (I find that I get more per hour with a 7½ lb. charge of fermented leaf per tray than 9½ lb. or more) I never turn my tea, only level tea, as the third tray is drawn out before placing in fourth sieve.

I promised you the results of Messrs. Jackson's hand tea roller made by Messrs. John Walker & Co., Kandy, in January last. This roller cost Rs. 475 nett. It is fitted with pulleys, circular cross action bars of box, also 4 on each side under base sliding plate of table, which decidedly makes work lighter, as I found by trying it at first by mistake without the pulleys. Since I have had the machine I took off the hopper fixed on top of box and deepened the box 6". The original size of box when received was 14½" high, 16½" wide each way; increased 6"—present size of box 20½" 16½". (The measurement given is outside; the correct for inside is 18½" by 15½") The box as first received rolled about 50lb. withered leaf; now it will roll 85 lb. viz., experiment on 2nd April 1885:—1st roll 85lb. withered leaf in 1 hour; 2nd, 76lb. withered leaf in 1 hour; or 161lb. in two rolls in 2 hours or 229lb. green leaf in 2 hours. This was rolled by 4 coolies, 1 coolie tending; total 5. On 19th March, it rolled 586 lb. green leaf in 5 rolls with 6 coolies; on 2nd April 419lb. green leaf in four rolls with five coolies; that is, 4 coolies rolling, 1 coolie tending leaf. When the quantity of leaf required over two rolls, one or two coolies extra are taken on to spell the other.

I feel sure when this machine is connected to water power it will roll in half-an-hour or three-quarters of an hour the same quantity of leaf better than with hand power in one hour. I would note that the leaf even with the large quantity of 85 lb. was very well rolled—quite as well as done by the Universal, from which so far I have only been able to get from 50 to 60 lb. of leaf well rolled.

I have deepened the box of the Universal 6", but as yet have not been able to see how it acts, as I have not water sufficient at present to work it. When I deepened the box of the hand-roller I increased the weights by 7lb. each side, or 15lb.

I will let you know how the Universal roller works with the increase in size of box as soon as I have water sufficient to work it—streams are lower this year than ever I have known them before.

I have made Jackson's afterdo everything. Never use a hand sieve. I have additional sieves to fit in on top, deck on deck, in fact a four decker. It does its work very well indeed: takes both dust and flat tea out, etc. What will Jackson say?

Theberton work of Sirocco No. 637 in one hour from 10.30 to 11.30

Time of trays put in Sirocco.	No. of trays.	Time of trays dried.	Temperature.	Remarks.
10.30	1	10.45	270	Each tray had 7lb. of fermented leaf.
10.30	2	10.50		
10.31	3	10.55		Temp. of Sirocco did not exceed 300. Sirocco fired for the hour 34lb dried tea.
10.31	4	11.		
10.47	5	11.5		
10.51	6	11.10	300	
10.54	7	11.15		
10.58	8	11.20		
11.04	9	11.25		
11.09	10	11.28		
11.13	11	11.30	280	

77 lb. fermented leaf made 34lb. tea in an hour.

Note.—In a trial I had on the 2nd, I got 86lb. fermented leaf done in the hour, but the 77lb. in this trial was more carefully done.

REPORT OF THE DEPARTMENT OF AGRICULTURE, WASHINGTON, FOR 1884.

We are indebted to the courtesy of the Commissioner of Agriculture, the Hon'ble G. B. Loring, for a copy of this very interesting report. It is divided into seven parts, consisting of separate reports by the Chemist, the Botanist, the Chief of the Forestry Bureau, Chief of the Bureau of Animal Industry, the Entomologist and the Statistician; and the entire working of the department is summed up in a report by the Commissioner himself.

We thus find that the Bureau of Animal Industry was only established in May 1884. Its sphere of duties embraces a wide range, and comprises (1) investigations in regard to the extent, nature, and means of combating outbreaks of communicable diseases among domesticated animals of the country. (2) Scientific investigations in regard to the nature and cause of contagious diseases among animals, coupled with microscopic investigation of American pork to prove the existence of trichinosis infection. (3) Development and need of the various branches of the live-stock industry. (4) The practical direction of the guaranteed system, which now forms one of the duties of this bureau. In fact, to use the words of the Commissioner, "the

labour of this bureau has been directed to prevent and control communicable diseases among animals in this country, to prevent the importation of such plagues from abroad, and to collect such information as is valuable to the stock grower, and necessary to the profitable development and conduct of our animal industries, and to enable us to secure free entrance for our animal products into the markets of the world."

The Bureau of Statistics is a very important one indeed. The extent of its labours may be gathered from the fact that, in addition to the special agent in London who reports upon the trade and industry of Europe, there are *ten thousand* correspondents in this department in the country, who furnish the materials for the statistical estimates of the bureau, which has been active during the year in the work of collecting the official statistics of State departments, boards of agriculture and commercial organizations, exploring the domain of fact in all departments of agricultural effort and experiment, and railroad transportations.

The work in the Bureau of Botany has, it is said, been "prosecuted with vigour." Much useful work in the way of distributing plants, seeds, fruits, grasses, &c., and answering enquiries from correspondents, has been done. This is a branch which, in its separate report, abounds in some very interesting information, but being very technical, we shall at a future time consider separately.

The Bureau of Chemistry forms an important feature in the report. It had under investigation the following work—(1) study of American cereals, with reference to the composition of the grains, their relation to moisture, variation in size, &c., as influenced by environments. (2) Study of the "Roller Milling Process" for the manufacture of flour—the results comprising both a physical and chemical examination, which are considered of great interest. (3) Baking experiments with flours of different grades from all parts of the country. (4) The examination of American dairy products; some of the results are to be found in the report of the Chemist, which will be noticed in future articles. (5) Extended investigation of maple sugars and maple syrups, which tends to show the presence of numerous spurious adulterations to be found in the market. (6) An investigation of soils, with a view to their exhibition at the New Orleans, Worlds Cotton and Industrial Exposition. (7) A study of the sugar industry of the country, including experiments and practical work with Sorghum, and an examination of the status of the beet sugar industry on the Pacific coast. The labours of this bureau are fraught with interest, and we purpose, at a future date, to write more fully on this point.

The Bureau of Entomology has continued in its various lines of usefulness. Important discoveries have been made as to the insect destruction of forest trees, as well as cereals, and fruit trees. An important feature in this bureau is that while preserving the scientific nature of its researches, it has sought to bring the results of its labours within the comprehension of average readers, by eliminating from its reports such technical descriptions as would not be appreciated by the mass of intelligent farmers. This is a point upon which we lay much stress, as it is too often lost sight of in the no doubt creditable endeavour to produce strictly technical and scientific reports. This is a weakness most observable in the reports received by the Government of India from its provincial administrators. This bureau has had under consideration the subject of the phylloxera, the promotion of silk culture in the United States, and the distribution of literature, silk-worm eggs, and mulberry trees to all such as may apply for them.

The investigations of the Forestry Bureau bring to light some alarming features of this industry in the Northern States. Much was done in the way of eliciting replies to circulars regarding parts of the country deficient in natural growth of trees. Instructions were printed and distributed in the best plan of planting, to avoid the mistakes and consequent losses which so often discourage the planter. The agents of the bureau have made personal observations in regard to the growth and preservation of forests. Their labours in this direction have been attended with more or less success. But official returns showed a steady diminution of forest area. The great pine forests of the north-west are said to be depleted

to an alarming extent, but efforts were being made to guard and protect them.

We have gone carefully over this report, and have seldom perused a Government production of more interest. While maintaining its official stamp, it is full of instruction, and has repaid a perusal of the varied and interesting information it contains. It is thoroughly practical in all its parts, and there is an air of masterly handling in all of its departments, without superfluity. We would invite the attention of the Government of India to this volume, and would suggest that a report on the lines adopted by the Department of Agriculture at Washington, might with much advantage be brought out in India. If the several departments of the Imperial and Provincial Governments would embody the vast information they obtain annually from their district officials, into a handy and popular form such as that we have before us in the report of the Washington Department of Agriculture, it would, we think, go a great way in bringing the mass of valuable information within easy reach of all classes, and thus give an impetus to the study of important subjects in domestic and political economy.

We propose extracting and giving to our readers from time to time selections from the report of such matters as we think will be of interest.

AGRICULTURAL DEPARTMENT OF BENGAL.

(Continued from last week.)

IN respect to the larger subject of *Agricultural Improvements*, it is not considered possible or expedient to lay down any exact rules; the Director's official duties in this respect being, for some time to come, limited to observation and experiment. Some of the subjects to which his attention may be usefully devoted are enumerated in the Lieutenant-Governor's letter of June last; but as the department at present exists on the basis of a provisional sanction, it is considered better to trust in this branch of the subject, to useful action in concert with established Societies (such as the Agri-Horticultural and Zoological) interested in the matter; and to the employment of the Cirencester graduates who are at the disposal of Government, rather than that the Director should rely solely on his individual exertions. In this view, arrangements have been entered into with the Agri-Horticultural Society, by an increase in the Government subsidy, by which its active co-operation in aid of the Agricultural Department has been secured.

Among the miscellaneous matters that are to engage the attention of the Director, is the important one of the prevention and cure of diseases among cattle; for nothing tends more to stability and progress in agricultural operations than the preservation and improvement of cattle, upon whose labour agriculture in India so largely depends. Therefore fodder for cattle and fuel for the people will take up a large share of the Director's attention. To extend the usefulness of the Indian and Economic Museums, in communication with the Government of India, will fall within the province of the Director of Agriculture, who will also be usefully employed in connection with exhibitions in India and in foreign countries, where it is of the utmost importance that the great natural and industrial resources of Bengal should be fully represented.

With regard to the employment of those graduates of the Cirencester Institute who have returned to India, it is proposed to utilize their services in such a way as suggests itself to be the most useful. Thus agricultural enquiries are for one year to form the main object of their attention, their other duties being regulated accordingly. They are to make themselves thoroughly acquainted with the native systems of agriculture in selected localities, where it may be found possible to introduce improvements. While engaged in this work, these officers are requested to secure the active assistance of members of the native community interested in agriculture. In this connection the Lieutenant-Governor lays much stress on the co-operation of officers of the Opium Department in Behar, as they are engaged in duties which bring them into intimate relations with the agricultural population. For this purpose, the Board of Revenue will issue the necessary instructions. Committees of European and native gentlemen are to be formed, who might interest themselves in getting up local

exhibitions with the advice of the Director. The Lieutenant-Governor will be prepared to make reasonable contributions towards the expenses of such exhibitions from Provincial Funds.

With reference to agricultural experiments, it is pointed out that officers desirous of testing the merits of agricultural implements, should make the trials on the ryot's own grounds as far as possible. This is a move in the right direction; as the cultivator is more likely to adopt the new method under these circumstances, and more practical good may be expected from such experiments, "than," as Sir Rivers Thompson correctly remarks, "if the experiment had been tried on a model farm, and the results recorded in blue books." It is further stated, in regard to this important point, that the people will not be induced to try experiments in this way unless Government are prepared to make good any losses they may sustain by following its advice. To this end, the Lieutenant-Governor will be prepared to make, in a moderate way to begin with, an allotment of funds to meet such contingencies.

With the foregoing general directions, the charge of this important department has been placed in the hands of Mr. M. Finucane, who is an officer of much experience in this particular department. He has for his assistants three able officers, viz., Mr. D. B. Allen, C. S., Mr. Ambica Churn Sen, C. S., and Mr. Sakhawut Hossen, Deputy Magistrate and Collector. Messrs. Allen and Sakhawut Hossen will be employed in Behar, and Mr. A. C. Sen in Bengal (possibly Burdwan). In regard to *Agricultural Research*, the Director will be under the control of the Board of Revenue; while in reference to *Agricultural Improvements*, he will be under the orders of the Revenue Department of the Secretariat. But he is at liberty to communicate direct, on all subjects, with local officers and heads of Departments. Such, in brief, is the programme laid down at present for the Director of Agriculture. We have no comments to make upon this measure, beyond this, that it has been a matter of surprise to us that the most important agricultural Presidency of the Empire should have been so long without such a department. The choice of the Lieutenant-Governor in the selection of a Director has happily fallen upon a gentleman who may be expected to grapple thoroughly with the vast field of enquiry opened out before him. We shall therefore await with interest Mr. Finucane's first report of his labours in the Agricultural Department of Bengal.

AEROLITES.

THE attention of the Government of India having been recently invited by the Superintendent of the Geological Survey of India to the subject of reports of falls of aerolites, Local Governments and Administrations were consulted as to the expediency of reviving the existing orders in those Provinces in which they had to some extent fallen into desuetude, and of extending them to other provinces. The replies received being favourable to the proposal made by the Superintendent, the Government of India directed that the orders issued in 1866 on this subject should be considered of general application. Col. Oldham, the then Superintendent of the Geological Survey of India, submitted a proposal for the approval of his Excellency in Council, that instructions might be given to the Local Governments, &c., that all falls of aerolites, together with the papers relating to them, should, in the first instance, be forwarded to the Government Geological Museum, Calcutta, and that at the same time orders should be given to the Director of the Museum that specimens of all such falls should be forwarded without delay to the British Museum, with all particulars as to the date, &c., of the fall. In fact, that this Museum should be made the medium of transmission of such specimens to the British Museum, with which we are in constant communication, and with which we have established a system of mutual exchange. By the adoption of this plan, the "Indian Museum" would not be deprived of the many opportunities of adding to its valuable collections of Indian aerolites, while the British Museum would be more certain of receiving good specimens of all that come to Calcutta. The following note on the Observation and Collection of Aerolites which contains the instructions referred to above, was drawn up

under the direction of the Trustees of the British Museum in 1863, and circulated by Government in 1865 :—

There are two varieties of aerolites, or meteorites, that have been seen to fall from space. The one consists of stony masses, often containing particles of iron; and of these many have been observed in their fall; the other variety is composed, for the most part, of iron. The actual fall of iron aerolites has been but rarely witnessed, though many masses of metallic iron have been found on the earth's surface, of the meteoric origin of which there can be no doubt.

It is a matter of great interest and of importance to science that as many as possible of these bodies should be collected for comparison, and that all the circumstances accompanying their fall be carefully recorded; and persons who, in the event of a "fire ball" being seen, or of a mass having fallen in their neighbourhood, will carefully collect facts regarding them may make a very valuable contribution to the science.

For this purpose, inquiries should be instituted at once into the circumstances accompanying the fall of any meteoric mass, and into the state of any such mass, when it has fallen; and as regards any meteoric appearance in the sky, it will be found advisable, after noting carefully the point in the heavens at which the meteor made its appearance, to give, as accurately as possible the direction of its track and the point at which it disappeared.

Where it is possible this track should be delineated on a diagram.

The points to which especial attention is invited are enumerated in the following two series of inquiries :—

The first series relates to meteoric phenomena in the heavens, and their association with the fall of aerolitic matter to the earth.

1. Note the exact position of the observer, according to latitude and longitude.
2. Give the hour, day of month, and year.
3. Give the apparent size of the luminous ball, as compared with the full moon.
4. Its shape; whether round, pear-shaped, or otherwise; and, if elongated, in what direction.
5. It is particularly important to note the place where the meteor is first seen like a star, and from which, as it moves, it may appear to be increasing in size.
6. State the duration of the phenomena; and
7. Whether the ball again dwindles away to the semblance of a star, and then disappears, or whether it retains to the last its full size, or then, as is often the case, divides into several balls or stars.
8. Give the colours.
9. Record any facts that can be gathered concerning detonations or noises accompanying the other phenomena.
10. Endeavour to collect statements relating to the actual fall to the earth of any solid bodies.
11. Do they consist of stone, or iron, and is there anything peculiar in their structure?
12. Was the body red-hot, or warm, or did it exhibit evidence of having been warm outside and cold within—as, for instance, by being hot at first and intensely cold afterwards?
13. It is desirable, further, to notice the depth to which, and the direction in which, the aerolite has penetrated the earth: also to state the nature of the soil, the effect produced on it by the aerolitic mass, and the position in which the aerolite was found to be lying in the ground.

The second series of inquiries has for its object the acquisition of a more precise knowledge regarding the aerolites themselves. For this, it is important to preserve, and to collect, for the purpose of analysis and of scientific comparison, as many of these bodies as possible; and the following suggestions are offered in the hope of promoting this object:

1. Endeavour to get the meteorolites as soon as possible after their fall, to prevent them from being injured, fractured, or wetted.
2. If not entire, try to procure fragments.
3. Should persons or Museums not be willing to part with them for the British Museum, then procure drawings, photographs, models, or casts; accompanied by an accurate description of their colour, the external lustre, and, if broken, the

nature of the substance or substances exhibited by the fracture; and especially be careful to describe the form of the aerolitic mass, whether angular or rounded, whether prismatic, or otherwise exhibiting an approximation to any geometrical figure. Also state whether its surface be smooth, or marked by any peculiar kind of roughness, or pitted with hollows.

4. Catalogues of the meteorites in the local museums are very desirable, with statements of their weights, and also the time of, and other facts accompanying, their fall, as detailed above.

5. From masses of iron or stone still lying on the earth, and too large to be brought away, detach specimens of good size, say from 20 lb. to 50 lb. weight, and collect all obtainable information, with detailed descriptions, drawings, measurements, historical accounts, &c.

6. Iron meteorites should always be cut with a steel saw and emery.

The collection of aerolites in the Mineral Department of the British Museum is now, as regards the mass and size of the specimens the finest in the world, and any person who may be in a position to contribute additional specimens is requested to accompany them with an attestation as to the weight of the specimen, and facts regarding it such as the senders may be in a position to state on their own authority, or as may have come to them on authority which they have reason to accept as reliable.

Miscellaneous Items.

DURING the month of March 624,271 cwts. of wheat, valued at Rs. 25,14,488, were shipped from ports in Sind.

We hear that "foot-and-mouth" disease has made its appearance among the pack bullocks recently purchased by the Commissariat Department.

ABOUT 90,000 pilgrims paid the meli tax of one anna at Hurdwar this year. The total number who visited the place is put down at 120,000 persons.

DURING the thunderstorm on Friday morning last, week the house No. 17, Camac-street, was distinctly struck by lightning. Fortunately no casualty took place.

A CORRESPONDENT informs us that the number of decisions reversed on "revision," which go up from the Lucknow Court of Requests, is abnormally high now-a-days.

DURING the storm and heavy rain of Friday last at Serampore, at the house of Baboo Poran Chunder Singhee, Mooktiar, a cow was struck dead by lightning, and a man slightly wounded.

It is rumoured that the Forest Accounts Branch in the Comptroller-General's Office will be abolished, in consequence of the late notification of reductions in the several departments under Government.

THE Annual Horse and Dog Show, with which the Lancers associate themselves especially, comes off on Thursday and Friday near the 17th Lancers Horse Lines. The programme is a very "fetching" one indeed.

A CORRESPONDENT writes that he hears from a reliable source that the members of the Executive Council, and the Secretaries and other officials to the Government of India, will return to the Metropolis this year, at the end of August next.

We hear that Mr. Ozanne, head of the Agricultural Department, was robbed a few days ago at Lanowli where his office is at present stationed. A valuable watch and chain and some other ornaments were stolen from his tent. The police are inquiring into the matter.

PEOPLE seem to be flocking into the town seeking relief, and not only in Calcutta itself, but also in many parts of the suburbs. In Mooktaram Baboo's street, hundreds of poor assemble daily for the purpose of obtaining relief in the chattram of Raja Rajendra Mullick Bahadur.

RAIN, we hear, is much needed both at Coonoor and Kotagiri. The coffee blossoms, which shot out freely a short time ago, are all being scorched for want of a few showers of timely rain. Tons and tons of coffee are thereby being lost. A bad look-out for planting interests this season.

We hear that Mr. H. L. F. Fowler, a graduate of the University of Oxford and a son of Mr. J. T. Fowler, Inspector of Schools, Presidency Division, has been appointed Head Master of the Government Madrasah-i-Azam, which institution has been raised to the standard of a High School.

MR. ANDERSON, Veterinary Surgeon, Assistant Superintendent, Horse-Breeding Operations, Punjab, has obtained sixty days' privilege leave. His duties will be conducted during his absence by Mr. B. L. Grover, Superintendent of Horse-Breeding in the North-West Provinces and Rajpootana.

We hear that some philanthropists in the city are organizing a committee for the relief of those persons who have been made homeless by the scarcity in Burdwan, Beerbhoom, and Bancoorah. They propose to help the distressed adequately, and will visit every house in succession with a subscription list in hand.

THE week before last a fire broke out in the village of Parovies, thanna Avosgram, district Burdwan. Nearly half of the village was burnt down and many poor people of the place have become homeless.—By a recent fire, 446 thatched and brick-built houses were destroyed in Mooktagacha, but fortunately no lives were lost.

A CONTEMPORARY hears that Mohunt Rugnath Das of Jaintpore has signified his intention to present the town of Mozufferpore with a fire-engine. The inhabitants have every reason to be thankful for the generosity of the donor, considering their recent heavy losses through fires. We hope the noble example will be largely followed.

THE total number of dogs killed within the Civil and Military station of Bangalore during the month of April last was 129, at a cost of Rs. 35-6, which was defrayed by the Station Municipality. The total number of cobras killed within the past month was 33. The destruction of these reptiles cost the Municipality of the Civil and Military Station Rs. 12-12-0.

VISITORS to Cashmere will be glad to learn that the Maharaja has had rest-houses erected at all the stages between Bhimbar and Brinnger, and a supply of mules and coolies are kept at each stage. The enterprising Khansama of the Gujrat Dak Bungalow has also established a hill cart service between Gujrat and Bhimbar, en route to Cashmere. The fare is Rs. 11 per seat.

DRINKING water has become so scarce that people in the Bangalore Cantonment can only obtain a small supply of it daily, as people at home and other places obtain soup, by tickets. The Shoolay tank is completely dry, with the exception of a small puddle which the natives render thoroughly unfit for use by wading into it for the purpose of catching fish. This could easily be prevented by placing somebody there on guard.

We still continue to receive unfavourable accounts regarding the prevalence of cholera in the Presidency districts. In the sub-division of Bood-hoodh, the disease continues to commit fearful ravages. The local Moonsiff has applied to the higher authorities for an order, either to close his court for a fortnight, or to remove it to Mankoor. Want of pure drinking water is much felt by the people. All the tanks and wells are drying up.

OWING to the large quantity of cattle bought up by the Commissariat Department for transmission to Quetta, the price of this article of diet in the local market has risen two-fold, while the quality has deteriorated in an equal degree. It is thought that if the present demand continues much longer, the Indian substitute for the Roast Beef of Old England is likely to become as precious as the gammon of bacon hung up in Irish households for show.

THE 24th of April was a day which will be long remembered in Visianagram. The heat from 10 A.M. to 4 P.M. was intense and altogether unbearable, after which there was a terrific sandstorm which lasted for about an hour, pouring in columns of dust everywhere. When the storm had somewhat abated, it was followed by a smart shower of hailstones, each about the size of a sparrow's egg. Thatched buildings and trees suffered considerably, particularly mango trees, some of them being literally stripped of all their fruit.

A FIRE broke out lately at the Manockjee Petit Mill at Tardeo in the stores department, where a quantity of unpressed cotton bales were kept. On the fire being discovered the mill labourers were set to work at the fire-engines on the premises, and in a short time they succeeded in extinguishing it. The loss sustained is trifling—not more than Rs. 500, it is said. The public fire-engines were brought up quickly to the spot, but they were not used. Superintendent Crummy and other European police men rendered valuable assistance in extinguishing the fire, which is attributed to spontaneous combustion.

A Kutchee, not far from Poona, had a crop of melons, and, owing to several cases of theft from his field, he kept watch during the night. The other night he observed some one crawling towards the bed, evidently with no honest intention. He allowed the man to approach within arm's reach, and suddenly leaped upon him. In the struggle which ensued, the thief, a rascal, was joined by four others, who maltreated the owner of the melon-bed so severely that the man expired a few days after in the Sassoon Hospital. They were brought into Poona lately, and will most probably be tried during the present Sessions of the Saugum Court.

Selections.

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The Ordinary General Meeting was held on Wednesday, the 29th April, 1885.

COMMUNICATIONS.

Application from Messrs. Villmorin, Andrieux & Co., Paris, for seed of the Patna Opium Poppy. Complied with.

From Dr. Bonavia, Etawah, asking for information regarding the "Gilla." He writes—

"Dhobis up here, and probably also down in Bengal, use a curious kind of nut for crimping linen, without using any crimping irons. This nut they call in Oudh 'Gelha,' and here 'Chian,' the latter means a seed. They say it is brought from Bengal and sold in Cawnpore. The pods are long and many seeded, and the seed is of the size of a small and fat pocket-watch, of a horse-chestnut color, and with highly polished sides. Dhobis cut one side, and scoop out the kernel; then they introduce two fingers into the cavity, and quickly strike the damp linen forwards with its polished surface. This crimps it beautifully crossways.

"I believe you have in the hills east of Bengal, some kind of Acacia which produces a long broad pod, with this seed in it. Can you kindly give me the botanical and local name of it, from the above description?"

"A new interest attaches to this 'Gelha.' A lady took one with her to England, to crimp her child's linen, 'Dhobi-fashion,' and shewed it to Mr. Ruskin. He has undertaken, I am told, to set up a village with work people using nothing but primitive implements. He was so interested in this primitive Indian crimping machine, the 'Gelha,' that I fancy he has some idea of adopting it in his primitive village. The upshot is that I have been given the task of finding out the botanical name of the tree which bears this interesting crimping implement. It is very efficient. I know the seed, and have seen it used, but have not its botanical name. If you can kindly help me in this matter, you will oblige me, and will confer a favor on Mr. Ruskin."

The Deputy Secretary stated that the seed to which Dr. Bonavia referred was that of the *Eutada scandens* (Benth.) E. Purstha (D.C.) the *Mimosa scandens* of Linn. and Roxb., a large climber common to many parts of the Tropics and found in Sylhet, Nepal, Ceylon, Java, the West Indies, &c. The Hindustani name *Gilla* appears to be commonly used, but it has many other names, *Uriya* Geredi, *Nipalese* Faugra, *Bombay* Gardal, *Ceylon* Mahapawela, *Tel* Gilla-tige.

According to Royle (Illus. of Botany of the Himalayas, Vol. I, p. 183) the seeds are used by the natives for washing the hair, and Voight (p. 256) says by the ghaat people as an antifebrile. Drury mentions that it is employed as an emetic in Java. The seed is made into snuff boxes in the West Indies, and according to Dr. Birdwood (Cat. of Vegetable Products of Bombay Presidency) "the pods are used by the police there." Although the pods are of great size sometimes 6 feet and more long and 4—5 inches broad, it seems a strange article for the police to use. Gamble says the "seeds are eaten after roasting in water, the kernels are used by the Nipalese for washing their hair, and in Bengal by washermen for crimping linen." The seed is sold in the bazar for medicinal purposes, and is used in a powdered form; it is administered as a stimulant, but this use is not mentioned by O'Shaughnessy or others. Dr. Watt in his Economic Products of India says that "an oil is made from the seed, the properties of which are unknown." But the use made of it by the *Dhobis* seems the most general.

EARLY AMBER SORGHUM.

Messrs. Minchin Brothers & Co.'s report on the result of their experiment with this Sorghum, is interesting; it seems curious that hitherto all attempts to make chrysalizable sugar from it in India should have failed, while in America it seems to be recognized as fit to replace Sugarcane in many places. They write:—

"With reference to the Sorghum seed you kindly sent us last year, we sowed the seed in August and harvested the crop at the end of November. We worked Sorghum in our Diffusion apparatus and treated the juice on the same principle as our sugarcane juice, but the syrup obtained would not crystallize.

"We consequently sent the syrup to the distillery and manufactured very good spirit, but here also we can give you no quantitative result, as having lined and sulphured the juice and exposed it to high temperature, we had by this manipulation destroyed much of its value as a spirit material.

"Some of the juice indicated 10 Beaume, the same as cane juice, but some plants showed miserable density and were very stunted. The acclimatized seed is evidently not successful, we shall make a small planting in the factory this year, and try it again, as a spirit material, fermenting the juice at once."

In a subsequent letter Messrs. Minchin attribute the want of success in some measure to the method of selecting seed in this country. They also kindly agree to make experiments with "Alapoor Joar" alluded to in the last Proceedings.

RICHARD BLECHYNDEN, Junon,
Deputy Secretary.

THE AGRICULTURAL DEGENERACY OF INDIA.

AN INQUIRY INTO ITS CAUSES

(FROM A NATIVE CORRESPONDENT.)

In your issue of the 23rd January a correspondent comes forward to correct my errors. I have to request him not to confound higher education with high pressure and a revolutionary system of education. This is the third time that I have had to point out the distinction. The correspondent speaks as if I had attributed the agricultural degeneracy of the country solely to higher education. Evidently he had not read or understood all I had said on the subject. I had to touch upon the high pressure and revolutionary system of University education only in connection with the labour question. Even here this is only one of the causes of the degeneracy of labour, though it is a very widespread and infectious cause in creating a spirit of aversion to manual labour, and an inflated love of leading an easy life as a mark of a rise in society and gentleness. With regard to scientific agriculture, the correspondent admits that I do not undervalue scientific agriculture, and I pay sufficient importance to it. He admits also that native farmers have some practical knowledge of the advantages of deep ploughing, manuring, rotation of crops, etc. If they know the advantage of these, what is the cause of the ryots not improving their lands even this much, to the best of their knowledge and skill? The cause cannot be owing to want of knowledge, practical or scientific. If the correspondent maintains this position, as he does, he contradicts himself, and his argument is quite inconsistent with his admission.

I value the scientific knowledge of a profession more than the practical knowledge. But I must say that practical knowledge cannot be despised, if productive of good results. This is what I said in my reply to your correspondent "C. S. S." This is no eulogy of native skill. What is Science? It is but practice reduced into theory. When there is not much of a technical or scientific character in a profession, practical skill cannot be undervalued. The correspondent appears to be more a theoretical than a practical person. The difference between scientific agriculture and practical agriculture is not so great in their fruits as the optimist correspondent seems to think. He opposes the correctness and accuracy of my statement, that for a poor ryot of limited means "the increased out turn will not pay the increased cost and outlay," and he says further that the cost will not be great for the poor ryot. He cannot be allowed to make this bare assertion and run away. We want figures. Let us take, for instance, wet cultivation, where the native ryots spend much labour and skill. A ryot with a pair of bullocks is able to cultivate about four acres of nunjah lands. The bullocks are used for ploughing in sowing and transplanting seasons, and in stated periods before these times; for carting manure to the fields in dry seasons; and drawing water by water lifts for crops raised in gardens under wet cultivation, and in nunjah lands if the water-supply be insufficient from tanks or canals; and for miscellaneous purposes. Bullocks for drawing ploughs in black cotton soil range from Rs. 70 to Rs. 100 a pair. The draught involves heavy work and exertion in proportion to the depth of ploughing. But in nunjah lands the ryots are careful not to risk valuable large sized bullocks in drawing ploughs, as the work is very heavy for them to draw the ploughs wading knee deep through the clay mire, chiefly when the wet method is used. As the ground is turned into a mire before transplanting, an improved plough will require much stronger bullocks than now ordinarily used, at not less than Rs. 80 a pair, even for the simple plough referred to. The ploughing match on the loose sandy soil of the Saidapet Farm cannot be taken as the standard for the ryots on ordinary occasions.

The correspondent undervalues the bullocks for the plough which he recommends. In Madras and its immediate neighbourhood there is not so great a demand for bullocks as in rural places. The bullocks which he values at Rs. 40 a pair will fetch a much larger price in rural places. With regard to manuring, the ryots are not contented with mere vegetable leaves. In this district, whose ryots are reckoned among the most skilful in South India, varieties of manures are used, like farmyard manure, decomposed vegetable ashes and kitchen sweepings, tank silt, which is a compound of decomposed vegetable, mineral, and animal substances; nitre soil or salt earth is also largely used. With regard to farmyard manure, the fold system is generally adopted, by which sheep and even cows are folded over the ground previous to cultivation. Thus the dung and urine are secured, and in sheep the strong smell which scientists would call ammonia, is highly valued. In the selection of vegetable manure great skill is displayed. For cultivating nunjah lands, according to the best skill and knowledge of natives, is required about Rs. 25 per acre, including labour, manure, seed, &c., setting aside taxation altogether. The average best outturn per acre is Rs. 70 worth of paddy, and Rs. 7 worth of straw, taking the price of paddy at 20 Madras measures per rupee. On dry lands the cost of cultivation per acre is Rs. 12, and the average best outturn is Rs. 35 worth of dry grain, at 20 Madras measures a rupee. In cotton cultivation the average best outturn is Rs. 60 worth of cotton per acre. The outturn depends on good weather and sufficient water-supply, without which all the cost of cultivation is so much loss to the cultivators. For scientific agriculture, and for the use of improved implements, the costs will be 50 per cent more, or even double. Taking the increased cost to be Rs. 15 per acre, will the increased outturn by scientific agriculture be above Rs. 60 worth of produce on four acres of nunjah lands? We want figures of increased outturn to be guaranteed. This is the way the poor ryots calculate their income while wealthy mill-owners pay care for only small dividends and not for recouping the increased expenditure.

As a matter of fact, is the increased outlay and cost paid by increased outturn in the Saidapet model farm? I want to see the

farm during my stay in Madras. The outturn of paddy cultivation there must be below the outturn of fields cultivated according to native skill and knowledge. There may be special causes for disadvantages and smaller outturn. I do not ignore the advantages of scientific and improved methods of agriculture as the correspondent thinks I do. The non-adoption of scientific methods can never be taken as the cause of the degeneracy of agriculture in this country, even according to the best skill and knowledge of natives. Even according to the native method, do our ryots plough and manure their fields as well as they could? The correspondent urges scientific agriculture as an effective remedial measure to check the exhaustion of the soil. He is very right in prescribing this effective remedy provided the people have means to adopt it. But he only prescribes the medicine for the disease. As men do not get disease for want of medicine, so the soil in this country does not deteriorate owing to non-adoption of scientific agriculture.

In most instances, except in cases of petty peasant farmers, landlords or landowners are not the cultivators of the soil. Even those landowners who used to cultivate their lands at their expense, have abandoned the panna, as it is called, and have adopted and are adopting the system of leasing out their farms for varam or certain fixed payment. On account of costly labour, and on account of the hardships in collecting or buying manure and other difficulties, the lease system is found to be preferable. When the lessee spends labour on the fields he cultivates, it is so much saving to him and to the members of his family; but a non-labouring landlord has to lay out money for labour. What is a gain to the farmer in a pecuniary point of view is so much a loss to the latter class. Under these circumstances lands are leased out, and the lessees have no interest in the permanent improvement of the soil, as their tenure is temporary, extending over a short duration, sometimes of a single crop a year, and as the increased outturn will have to be divided between the lessor and lessee, the lessee's portion on an average ranges from 1/3 to 2/3 share of the produce. While it is doubtful or uncertain whether the increased outturn will cover and pay the increased cost and outlay by the adoption of scientific methods when the landowner himself cultivates his fields at his expense, it is not in human nature for a lessee to adopt scientific agriculture, when it will be a far less paying concern, as far as his share is concerned, for the self-denying and disinterested profit of his landlord. On account of poverty and various difficulties and hardships, landlords find it their interest to abandon their panna and lease out their lands. The lessees in their turn, on account of their relationships to the fields they cultivate, cannot be expected to spend much on cultivation and permanent improvement. In very rare instances rich landlords help their lessees in several ways. But in the majority of instances the crops depend upon the enterprise and skill of the lessees only.

That the agriculture of the country is degenerating is the general cry of many ryots. In several exceptional cases the soil may not have deteriorated, but in a good many cases the grievance is real. Persons like Sir James Caird, of the Famine Commission, who had studied the condition of the agricultural classes, have admitted the fact. He mentioned the rich district of Tanjore as an illustration. He attributes the degeneracy to petty peasant farming and subdivision of landed property according to Hindoo law. Though the facts may be true, their injurious influence upon the degeneracy of agriculture is extremely small. The land-owning classes, who form the mainstay of the Government and who are the great sufferers, throw the chief, though not the whole, blame on the Government and its revenue administration. According to their complaints, when money grows scarce among the agricultural classes, when they loyally pay their water tax to the last pie, while their irrigation works and tanks are not kept in good condition equal to the good demand, when the water-supply is quite insufficient for irrigation, when the Forest Laws, extinction of communal rights and various incidences of taxation seriously injure the agricultural interests of the people directly or indirectly. When labour grows costly, when the people are deprived of free pasture for their cattle, and when they are subjected to similar hardships, I do not know how the state of things can be otherwise, and how scientific agriculture can mend them.

Being a landowner and shareholder of a village myself, the grievances of the people exactly coincide with my experience upon which all my statements are founded. The ryots find it impossible to improve their lands. In this connection I condemned the system of double taxation chiefly on nunjah lands in my speech at Ponnappa's Hall. In spite of the special rulings of the Revenue Board standing orders, taxes are levied both for lands, and the trees on them. The existence of trees on the cultivated land causes permanent injury to it by contraction of space, by their shadows, by their roots absorbing the manure and hindering ploughing operations, by the topping and falling of leaves and fruits, and by a thoroughfare being made by the palmyrah climber for each tree yielding produce no less than twice a day even through full crops. Such difficulties, hardships, and injuries have been so miserably increased by the recent action of the revenue authorities who have have had the generosity to make out the seedlings and trees (of spontaneous growth) to tree pattadars at the expense of land pattadars in spite of the Statutory Laws of Government (according to Settlement Act), justice, and common sense which should respect the usufructuary rights of a landholder especially when they are of spontaneous growth. When a dispute arose about the trees that were seedlings at the time of the Revenue Settlement, but have grown since, one Collector decided that it was only justice that the trees in dispute should be made over to the land pattadars on whose lands they had grown spontaneously. On a petition for review by tree pattadars, another Collector has reversed the decision and has made over the trees to the tree pattadars.

What is still more outrageous is that the land pattadars who removed the grown-up seedlings injurious to their fields, by virtue of the right conferred on them by the previous decision, have been

served with a demand exacting the revenue penalty of thirty years' highest assessment on each seedling removed with an order for attachment and criminal prosecution if the heavy penalty be not paid at once, without showing the least courtesy and justice to the real sufferers by calling upon them for explanation and defence. Among the unhappy sufferers thus outrageously treated, I myself am one. In improving the paddy fields over-grown with palmyrahs and seedlings to the extent of from 80 to 100 per acre my coolies removed ten seedlings whose aggregate value would not be even 10 annas. For removing these ten seedlings I have been served with this outrageous demand of thirty years' penal assessment, which is no less than Rs. 18 annas 12. The treatment is for the exercise of ownership on seedlings spontaneously grown upon the ryots' fields according to most sacred and inviolable natural rights. Is this justice, wise administration, taxation, extortion or highway robbery? If this can be said of a person of my position and respectability, what may be said of those that are less wealthy and less influential? In the face of such difficulties presenting all possible obstacles for the improvement of the soil, what is the use of speaking of scientific agriculture? I do not exaggerate things, nor do I assume the role of a demagogue and an alarmist. It is a truth, and a sad truth, that the country is greatly degenerating. Whatever be the honorable intention of the Government, whatever be the public and private virtue of the majority of European officers, it cannot be denied that there are serious defects in the administration for want of sufficient knowledge of the condition and hardships of the agricultural classes by the well-meaning and justice-loving British Government. These defects require immediate check.—*Madras Mail*.

CULTIVATION OF THE DATE PALM.

DR. E. BONAVIA, of Etawah, furnishes the following interesting particulars regarding the culture and fertilization of the Date Palm, employed in Arabia and along the shores of the Persian Gulf. These notes were primarily intended for the information of those who had in charge the experimental patches of date palms in Oudh, the trees of which were raised from seed imported from Arabia.

Dr. Bonavia writes:—

"I need hardly mention that the flowers of the date palm are of two sexes, the male and female flowers being borne on different trees. The Arabian method of cultivation is this: Only female trees are planted, in large groves, the palms being put 12 or 15 feet apart. In order to do this they plant only *offets* (not seeds, as the sex of these cannot be known before they flower) taken from the foot of the female trees, when these offsets have attained the weight of three or four seers, that is, after five or six years more of growth on the parent tree. I found September the best season for planting offsets in Oudh. They are watered daily, or less often, till they strike, and afterwards at longer intervals. In the Persian Gulf groves consist of 80 to 200 palms. They should be protected from cattle; other crops can be grown between the rows; and there should be some means of irrigating the palms. In short, after striking, the trees should be treated in every way as other fruit trees, from which superior fruit is desired, each palm having a large *thala*, which should be periodically filled with a top dressing of any old manure available, such as cow, horse, sheep, goat, or even fish manure. Only the decayed lower leaves should be removed, and none of the green leaves should on any account be removed, as these are the lungs and stomachs of the trees. It should not be forgotten that fruit from offsets, if they are properly cultivated, will be like that of the parent tree, while fruit from seedlings will vary. Seeds can be sown in beds a few inches apart, and in a year, during the rainy season, transplanted into other beds, two or three feet apart, and finally planted out in groves 12 to 15 feet apart. The Arabs rely on artificial fertilization only to insure a crop of dates. The male trees may be any distance, and may have flowered a month or two before the females. The Arabs say that the male bunch of flowers is mature when, by "pressing it, a faint rustling sound is elicited. Also, if a slit is made in the margin of the flower-spathe, a peculiar odour is detected." Then the bunch of male flowers is removed from the tree, the spathe split open, the sprigs of male flowers carefully removed and placed in a suspended basket, protected from drought; and allowed to remain 20 to 24 hours before being used. As soon as the female flowers have burst their enveloping spathe, they are fit to impregnate. The cultivator then climbs the trees and inserts two or three male sprigs into each female bunch, and secures them with a strip of palm leaf. Date palms produce from 12 or 24 bunches of female flowers, but eventually only from eight to twelve bunches of dates are allowed to remain on each tree. If more are left, the dates, like other fruit, will be small, and many will fall off. They say that date pollen in this will keep fertile for one or two months, and used as occasion requires. The male flowers should, however, be slightly moistened with water to prevent the pollen from being scattered too readily while being used. In the

Persian Gulf artificial fertilization is considered a most important operation, otherwise the fruit is "abortive or blighted," without stones, and insipid. After fertilization the trees are not watered for six or eight weeks. I should wish now particularly to mention that in Arabia (and presumably in Oudh also) there are three distinct classes of date palms, (1) such as do not ripen their dates beyond the red or yellow stage, firm and dry, called *kharek*. This occurs in June and July. The dates of this class can only be preserved by cooking or curing in other ways. (2) Such as turn brown and become soft and juicy, but go no further. This occurs in August. These dates are called *rutub*. Even in Arabia this class of dates will not keep beyond a few days, as they turn sour. They can only be made to keep by proper curing. (3) Such as go beyond the *rutub* state, and ripen thoroughly into the *khorma* stage, which is sweet and semi-dry. This complete ripening in Arabia occurs in September. It is this last class of dates; which, after being collected and exposed to the sun, to rid them of their extra juice, are carefully packed into boxes and exported to Europe and America, without any further preparation. It should not, however, be forgotten that *khorma* dates have, of course, to pass through the two previous stages, namely, of *kharek* and *rutub*. All the classes of dates, at all stages, are edible and nourishing, and the Arabs feed on the one or the other kind all the year round. The shrivelled, unripe droppings, or such as are not fertilized, and therefore insipid, are given to goats, sheep, and cattle. In the Gulf, there are upwards of a hundred varieties of date palms. And, as something like fifty varieties of date seeds were sent to Oudh, there are sure to be in almost all the districts many puzzling classes and sub-classes of date palms. In the Lucknow Horticultural Garden alone there are upwards of 252 seedlings, varying from 12 to 18 years old, and I am informed that there are hardly two alike. In the districts there are only seedlings of the foregoing ages. Unfortunately, however, those in the districts are scattered, and unless artificial fertilization be practised, little will be known of their worth. The male flowers of the *khajoor*, or jungle date palm, are as good as any for purposes of fertilization, but the plants resulting from such crossed seed would be mongrels, although not improbably very good mongrels. With regard to protecting the ripening fruit from the depredations of bees, wasps, birds, and squirrels, the Arabs do little. Their plantations are on an immense scale, and the loss from these causes they consider unimportant. Sometimes they envelop the ripening bunch of dates in the leafy branches of some bush, sometimes in flags made of date-leaf matting; but where very choice varieties are grown, and the trees are small, they cover each bunch with a gunny bag. Squirrels in India are a great nuisance, and would tear the gunny and use the fibre for making their nests. Thorny branches of *bibool* and *hair*, tied round the palm stems, would, however, prevent them from getting up." *Planters' Gazette*, (English paper).

RHEA FIBRE.

THE Manchester manufacturers are now giving increased attention to the use of this fibre, and as it is our province to give all the reliable information obtainable upon every subject likely to benefit tropical planters, we place below some extracts from a paper recently published by Sir Joseph C. Lee, the well-known Manchester millowner. Speaking of the difficulty of cheaply extracting Rhea fibre, he says:—

The problem that many inventors have tried to solve is to make a machine or discover a process by which the work can be done effectually and cheaply, so that the fibre can be sold in London at £10 to £50 per ton in the ungummed state. Various mechanical appliances and methods have been invented, but only two of them seem to fulfil the conditions necessary for successfully treating the fibres. The first of these is a machine invented by Mr. H. Smith, and improved by Messrs. Death and E. Wood, of Leicester. It is claimed by the inventor that this machine will clean any vegetable fibre, and particularly Rhea or China grass. To this machine was awarded the prize of 2,000 rupees in accordance with the recommendation of the "Committee appointed by the Government of Bengal to conduct a trial of machines and processes for the extraction of Indian fibres" on the 24th November last year. The report states that the cost of a single machine is £55, that of a double one, complete, £100. A semi-portable engine to work two machines will cost £32 10s. The quantity of water required appears to be about 400 gallons per hour for one machine, but the water can be used twice over. The work turned out in ten hours by one machine is 2,200 lb. of green stalk. This quantity might be expected to give 3 per cent, an output of 66 lb. of good clean fibre. The value of this output at £50 per ton would be about 30s.

The machine is the property of the General Fibre Company, Fenchurch-street, London, and is doubtless a valuable patent, and will be useful in cleaning some kinds of fibrous plants. No Rhea fibre has yet been imported that has been treated by this machine, we can only judge of the practical value from the evidence contained in the official report. In this it is stated that 3 per cent of fibre can be obtained under favourable circumstances from every 103 lb. of green stems. This percentage will contain at least 15 per cent of resinous matter, which must

be discharged before the fibre is ready for the spinner. This will give 2.55 per cent of pure filasse—a small percentage, which cannot be profitable if the fibre is to be sold at £50 per ton. Another drawback to the value of the machine is the quantity of water required to clean the fibre. In a climate like India it is not always possible to obtain water in sufficient quantity. Therefore, if only 30s. worth of fibre can be obtained per day from one of these machines (as stated in the report), it can hardly be said to be a commercial success so far as the treatment of Rhea is concerned. The second plan of treating the Ramia or Rhea is one patented by M. A. Favier, and is a simple method of decortiating the stems of the plant on the fields where they are grown. It is as follows:

I visited the works at Louviers belonging to the Société de Crédit, accompanied by a director of the Company, Mr. Vian, Professor Urbain, Mr. Paterson, and Mr. Casper, of the firm of Messrs. G. W. H. Brogden and Co., the English owners of the patent, and by Mr. P. Nursey, the editor of the *Iron*, and others. We were shown samples of Ramia grown in France, Algeria, Egypt, India: all decorticated, some of them by the Favier process, others by methods unknown. Seven different growths of Ramia were selected and placed in a large boiler or high pressure kler. Probably half a ton of ribbons were thus under treatment, and when they had been thoroughly saturated by a solution of which one of the component parts, if not the whole, was apparently caustic soda, the top of the kler was fastened down, and steam at a high pressure (30 pounds) was turned in from the bottom of the kler. The boiling extended over a period of five hours. On the kler being re-opened the whole mass of fibre was seen in a black condition. Mr. Urbain took about a pound weight of ribbons and treated them as follows:—He washed them in cold water, then in a solution of hydrochloric acid, again in water, then in chloride of lime, and lastly thoroughly in cold water. The ribbons then appeared in the form of whitish gray filasse, ungummed and free from the brown pellicle; the fibres could then be easily separated from each other, and were apparently in the condition for treatment by machinery. The operation lasted ten minutes. The inventors claim that by their process 5 per cent of pure ungummed fibre is obtainable from the green stems.

I see little difference between the process I have described and the one used by bleachers of cotton cloth for dyeing or printing which is necessary to make the cloth chemically pure, and similar drugs are used to "kill" the husk and brown bark often left in the yarn; this is done without the least injury to the fibre. I am of opinion that the merit of the invention consists in the knowledge obtained by experiments, of the strength of the caustic soda required for destroying the pellicle and reducing it to a state of pulp without injury to the fibre. The after process is a clearing one; it removes the gum and pulp, and the chloride takes away any colouring matter that may remain. This invention may be considered a satisfactory and inexpensive method of ungumming the Ramia fibre, and if the patent rights be obtained by the producer of the yarn, it will add to its popularity.

I shall now deal with the cost and production of the plants and the probable future of the industry. Of late years the French have given a great deal of attention to the cultivation and utilisation of the Ramia plant. It has been grown in the basins of the Gironde and Rhone, in Algeria, and in Egypt. M. Norbert de Lundscheer who has written much on the subject, gives the following table, showing the latitudes in which the plant can be grown:—

Latitude of country.	No. of crops.	Names of countries corresponding to latitudes.
36° to 46°	2	Bordeaux, Grenoble, Avignon, Turin.
38° to 42°	3	Corsica, Sardinia, Madrid, Naples.
35° to 37°	4	Algeria, Tunis, Northern China, New Zealand.
25° to 32°	4 to 5	Egypt Delta, Lahore, China, Florida, Mexico, Chili, Buenos Ayres, Australia.
15° to 20°	5	Madras, Bombay, Cochin China, Brazil, Jamaica, Cuba, Hayti.
0° to 10°	5 to 6	Sumatra, Johore, Ceylon, Java, Venezuela.

He states also that an acre of cultivated Ramia can give 200,000 stems at a cutting, each stem averaging 14oz. In Algeria, where four crops a year can be grown, a profit of £19 12s. 6d. per acre has been obtained. If we take these figures as being correct—and I have not heard of them being disputed—we have 20,000 stems per acre, or 18,750 lb. weight, which will produce about 1875 lbs. of ribbons, and by the Fremy-Urbain ungumming process 937½ lb. of filasse, which at £50 per ton gives 534. per lb. I was told by the director of the Société de Crédit, &c., that they had signed contracts for 10,000 tons of ribbons at £10 per ton, to be delivered in two years, and that they were prepared to take 100,000 tons at that price. Therefore, if we take two tons of ribbons as costing £20, which will produce one ton of filasse; ungumming two tons, at £3 per ton, £16; charges, shipping expenses, £4, or 44d. per lb.—£40 per ton. A ton of cotton cloth can be bleached for £6 per ton; the ungumming process being a quicker one should not cost over £5 per ton.

Several companies in India are now growing Rhea, notably the Glenbrook Company, and a Company has been formed to plant 20,000 acres in Johore, where it is expected that five or six crops can be obtained yearly. It will be seen that before many years have passed an enormous quantity of this fibre will be shipped to Europe, and as the plant is perennial, and once planted will last a hundred years, some idea may be conceived of the yield in prospect. A manufacturing community like Lancashire cannot afford to ignore the new industry which will undoubtedly spring up within a few years. I readily admit that a vast sum of money has been lost by manufacturers in their attempts to develop this new fibre, but, as I have shown, the conditions are now somewhat

changed. Formerly the quantity of fibre imported did not exceed a year's average of 100 tons, consequently the value has been much affected by the demand, the price at some periods rising to £120 per ton and at others falling below £30 per ton. We have now the prospect of large supplies of the fibre at a reasonable rate and under favourable conditions. Makers of spinning machinery will do well to give their special attention to the preparation of machines capable of treating the long silky fibres of the Ramia. The French are already at work. During my visit to Louviers, the gentlemen who accompanied me were granted the privilege of an inspection of the preparing, carding, and spinning machinery, but this courtesy was denied to myself, on the plea that secrets might be revealed before they were secured by patent right. I was, however, shown the fibre in the silver and also in yarn equal to 10's, 16's, 24's, 30's cotton, all of which seemed satisfactory, and I have since received samples of the fibre I saw treated at Louviers, which are excellent. It will be asked, in what is Ramia better than cotton or hemp? I reply that it is better in many respects. It is nearer in appearance to silk than any other fibre, and, like silk, it is a non-conductor, or nearly so. It can be mixed with silk or wool, and it will give strength to both. It can be produced more cheaply than flax or hemp, and is three times as strong. It is stronger than cotton, and takes better colours—faster and more lustrous. It is invaluable for headstays, ropes, hose, sailcloth, cloth or waterproofing, clothing for men, Indian army clothing, furniture covering and hangings, cambrics, and summer dresses; and, in the words of a well-known chemist, "It is difficult to say what it is not good for. It is the strongest fibre in nature."

Mr. P. Nursey, C.E., Vice-President of the Society of Engineers who accompanied Sir J. C. Lee in his visit to the works at Louviers, reports as follows:

I may premise that the successful utilisation of the rhea fibre necessitates that decortication, or the stripping of the skin off the stems of the plant, shall be performed by a method which shall ensure that no fragments of the woody stem shall be left adhering to the skin in which the fibre is contained. Moreover, the stems must be decorticated as soon as cut, as the resinous matter in which the fibres are embedded rapidly hardens, a fermentation is set up which injuriously affects the fibre, and it is extremely difficult to deal with the ribbons afterwards; besides which, when decorticated in this condition, some of the fibre is left adhering to the wood, and great waste results. The process of decortication invented by M. A. Favier having been proved to be thoroughly successful in dealing with rhea, and having inspected its working on two occasions, I think it as well first to briefly refer to it, especially as it appears to me to be the most perfect, as well as the most natural, method of producing the ribbons containing fibre for further treatment by the Fremy-Urbain process.

M. Favier's process consists in submitting the stems of the rhea or other fibrous plants to the action of steam at a low pressure for a period of about twenty minutes. The apparatus required is of the most simple and inexpensive character, consisting only of wooden trough-shaped boxes and a low-pressure steam boiler, whilst the operation of stripping the stems after they have been steamed can be performed by unskilled labour, or even by children. This process insures the obtaining of the whole yield of fibre from the plant, without deterioration or waste, and at a small cost.

The Fremy-Urbain process is the joint invention of the distinguished French chemist, Professor Fremy, member of the Institute of France (who is well known for his researches into the nature of fibrous plants and the question of their preparation for the market), and M. Urbain, who is Professor Fremy's principal assistant in the Government Laboratory, Paris, of which the Professor is chief. The process consists mainly in an alkaline treatment under conditions which vary with the character of the rhea fibre to be treated. A most important factor in the success of the Fremy-Urbain process, and that which I regard as the crowning feature of the whole, is the special treatment of the fibre. Throughout the whole process there is not one stage to which exception can be taken on the score of danger to the ultimate fibre, whilst there is, on the other hand, a perfect harmony of arrangement and sequence of development.

It is unnecessary for me here to enter into all details of the operations as witnessed by me, and as fully and unreservedly explained to me by Professor Fremy. Suffice it to say that upon one occasion I saw about 800 lbs. of ribbons treated at Louviers, and upon a second occasion about half a hundredweight.

With regard to the question of dyed yarns, I may point out that it is essential, in order to take dyes, that the article to be dyed shall be chemically pure. I received Professor Fremy's emphatic assurance that there is nothing whatever in either the Favier or Fremy-Urbain processes which militates against this purity. The Professor, moreover, has a formula by which the purity or otherwise of the material to be dyed can be readily ascertained.

Taking into consideration the successful results I have seen produced, and the perfect condition in which the fibre can be turned out, I am of opinion that the Fremy-Urbain process is an invention of the highest importance, and, considering the value of rhea fibre as regards its strength and beautifully lustrous appearance when worked up, I am further of opinion that this material, properly prepared, would command a most extensive market. That this would be the case may be inferred from the fact that there is at present a great demand for rhea fibre, notwithstanding that it is more or less imperfectly produced.

From careful observation of the working of the Favier and Fremy-Urbain processes in conjunction, I am satisfied that, as far as the production of pure undamaged fibre of long staple goes, the two processes are in accord, and are thoroughly adapted for each other. Properly conducted, I feel convinced that their results must lead to an important expansion in the textile industry of the country.—*Planters' Gazette* (English paper.)

AN ALARMING DISEASE AFFLICTING A NUMEROUS CLASS.

THE disease commences with a slight derangement of the stomach, but if neglected, it in time involves the whole frame, embracing the kidneys, liver, pancreas, and in fact the entire glandular system; and the afflicted drag out a miserable existence until death gives relief from suffering. The disease is often mistaken for other complaints; but if the reader will ask himself the following questions, he will be able to determine whether he himself is one of the afflicted:—Have I distress, pain, or difficulty in breathing after eating? Is there a dull, heavy feeling, attended by drowsiness? Have the eyes a yellow tinge? Does thick sticky mucous gather about the gums and teeth in the mornings, accompanied by a disagreeable taste? Is the tongue coated? Are there pains in the sides and back? Is there a fullness about the right side as if the liver were enlarging? Is there costiveness? Is there vertigo or dizziness when rising suddenly from a horizontal position? Are the secretions from the kidneys scanty and highly coloured, with a deposit after standing? Does food ferment soon after eating, accompanied by flatulence or a belching of gas from the stomach? Is there frequent palpitation of the heart? These various symptoms may not be present at one time, but they torment the sufferer in turn as the dreadful disease progresses. If the case be one of long standing, there will be a dry, hacking cough, attended after a time by expectoration. In very advanced stages the skin assumes a dirty brownish appearance, and the hands and feet are covered by a cold sticky perspiration. As the liver and kidneys become more and more diseased, rheumatic pains appear, and the usual treatment proves entirely unavailing against this latter agonising disorder. The origin of this malady is indigestion or dyspepsia, and a small quantity of the proper medicine will remove the disease if taken in its incipency. It is most important that the disease should be promptly and properly treated in its first stages, when a little medicine will effect a cure, and even when it has obtained a strong hold, the correct remedy should be persevered in until every vestige of the disease is eradicated, until the appetite has returned, and the digestive organs are restored to a healthy condition. The surest and most effectual remedy for this distressing complaint is "Seigel's Curative Syrup," a vegetable preparation, sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White, Limited, 17, Farringdon-road, London, E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

Market-Place, Pocklington, York, Oct. 2, 1882.

Sir,—Being a sufferer for years with dyspepsia in all its worst forms, and after spending pounds in medicines, I was at last persuaded to try Mother Seigel's Curative Syrup, and am thankful to say have derived more benefit from it than any other medicine I ever took, and would advise any one suffering from the same complaint to give it a trial; the results they would soon find out for themselves. If you like to make a use of this testimonial you are quite at liberty to do so.—Yours respectfully,

(Signed) R. TURNER.

Seigel's Operating Pills are the best family physic that has ever been discovered. They cleanse the bowels from all irritating substances, and leave them in a healthy condition. They cure costiveness.

St. Mary-street, Peterborough, Nov. 20, 1881.

Sir,—It gives me great pleasure to inform you of the benefit I have received from Seigel's Syrup. I have been troubled for years with dyspepsia; but after a few doses of the Syrup, I found relief, and after taking two bottles of it I feel quite cured.

I am, Sir, yours truly,

Mr. A. J. WHITE.

WILLIAM BRENT.

Hensingham, Whitehaven, Oct. 16, 1882.

Mr. A. J. WHITE.—Dear Sir,—I was for some time afflicted with piles, and was advised to give Mother Seigel's Syrup a trial, which I did. I am now happy to state that it has restored me to complete health.—I remain, yours respectfully,

(Signed) JOHN H. LIGHTFOOT.

August 15th, 1883.

Dear Sir,—I write to tell you that Mr. Henry Hillier, of Yatesbury, Wiltshire, informs me that he suffered from a severe form of indigestion for upwards of four years, and took no end of doctor's medicine without the slightest benefit, and declares Mother Seigel's Syrup which he got from me has saved his life.—Yours truly,

(Signed) N. WEBB,

Chemist, Calne.

Mr. WHITE.

September 8th, 1883.

Dear Sir,—I find the sale of Seigel's Syrup is daily increasing. All who have tried it speak very highly of its medicinal virtues, and one customer describes it as a "Godsend to dyspeptic people." I always recommend it with confidence.—Faithfully yours,

(Signed)

VINCENT A. WILES,

Chemist-Dentist,

Merthyr Tydvil.

To Mr. A. J. WHITE.

Preston, Sept. 21st, 1883.

My Dear Sir,—Your Syrup and Pills are still very popular with my customers, many saying they are the best family medicines possible.

The other day a customer came for two bottles of Syrup and said, "Mother Seigel" had saved the life of his wife, and he added, "one of these bottles I am sending fifteen miles away to a friend who is very ill. I have much faith in it."

The sale keeps up wonderfully; in fact, one would fancy almost that the people were beginning to breakfast, dine, and sup on Mother Seigel's Syrup, the demand is so constant and the satisfaction so great—I am, dear Sir, yours faithfully,

(Signed)

W. BOWKER.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA:—SATURDAY, MAY 23, 1885.

[No. 21.]

Crop and Weather Report.

[FOR THE WEEK ENDING MAY 13, 1885.]

General Remarks.—Slight rain has fallen throughout the Madras Presidency, and showers have been fairly general in the Mysore State.

In Bombay there was light rain in parts of twelve districts. In the North-Western Provinces and Oudh, in the Punjab, and in the Central Provinces, rain fell in nearly every district during the week under report. Slight rain is also reported from the Nizam's Territories and the Central India and Rajpootana States.

In Bengal good rain has fallen in several districts, and prospects of standing crops have greatly improved, while agricultural operations have been facilitated. Rain was general in Assam.

In Madras agricultural prospects are unchanged, and are unsatisfactory in parts of the Bellary and Anantapore districts, where the standing crops are withering. The harvest outturn has been generally below the average.

In Mysore the season is reported to be drier than usual, but there will be no cause for serious apprehension if the June and July rainfall is regular and plentiful. The cattle are in poor condition from scarcity of fodder and water.

In Bombay and the Central Provinces preparations for the *kharif* crops are going on well. Scarcity of fodder and water continues in parts of Bombay. In the Punjab *rabi* crops are being harvested, and preparations are in progress for the *kharif* crops. In the North-Western Provinces and Oudh, the *rabi* harvest has been almost completed and threshing is going on. Some injury has been caused to grain on threshing-floors by the recent rain.

Agricultural prospects continue generally good in the Berars, the Nizam's Territories, and in the Central India and Rajpootana States. Ploughing and sowing continue in Assam.

Except that cholera and small-pox are present to some extent in most provinces, the public health is generally good.

Prices are on the whole generally stationary.

Madras.—General prospects fair except, in parts of Bellary and Anantapore.

Bombay.—Slight rain in parts of 12 districts. Preparations for *kharif* crops in progress in parts of 8 districts. Scarcity of fodder continues in four talukas of Belgaum and three of Dharwar, and of drinking-water in six talukas of Dharwar and four of Belgaum. Small-pox in parts of 13, and cholera, cattle-disease, and fever in parts of 10 districts.

Bengal.—Rain fell throughout the Provinces except in 1 or 2 districts; it has greatly improved the prospects of standing crops and pushed on agricultural operations. Prices of food-grains generally stationary. Public health good, though sporadic cases of cholera and small-pox are reported from some districts.

N.-W. Provinces and Oudh.—Rain has fallen throughout the Provinces. Slight injury caused to grain on threshing-floors. Markets well-supplied and prices steady. Cholera and small-pox continue in some districts.

Punjab.—Rain has fallen in nearly every district. A few cases of cholera in the Umballa and Mooltan districts, health otherwise generally good. *Rabi* being harvested, outturn in the Sialkot and Lahore districts somewhat damaged by rain. *Kharif* operations commenced. Prices of food-grains generally stationary.

Punjab.—Rain has fallen in nearly every district. A few cases of cholera in the Umballa and Mooltan districts; health otherwise generally good. *Rabi* being harvested, outturn in the Sialkot and Lahore districts somewhat damaged by rain; *kharif* operations commenced. Prices of food-grains generally stationary.

Central Provinces.—The weather has continued unsettled, with occasional showers of rain. *Kharif* ploughings have commenced. Cholera is prevalent in a few districts. Prices are steady.

British Burmah.—Cholera is still severe in town of Pegu, and is more so in parts of Akyab, Bassein, Thongwa, Amherst, and Shwegyin districts; some cases of small-pox in towns of Hensada and Ramra, and in Tharrawaddy districts; slight cattle-disease in some districts, and severe in one township of Bassein district. Weather continues hot.

Assam.—State and prospect of crops good. Cholera, small-pox, and cattle-disease continue. Ploughing and sowing in some districts progressing. General health good. Scarcity in north Lakhimpore continues.

Mysore and Coorg.—Sugarcane and paddy under tanks in some parts reported to be withering. Prices generally stationary. Cattle in poor condition from scarcity of fodder and water. Public health fair, but cases of cholera occur. Season drier than usual, but no cause for serious apprehension if June and July rain fall is regular and plentiful. Paddy, coffee, and cardamom crops in good condition. Prices of food-grains slightly risen. Prospects of season good.

Berar and Hyderabad.—Weather hot. *Kharif* preparations continue. Crops in Asfnagar taluk damaged to some extent by hail. General health fair, except in Shahabad taluk, where cholera continues stationary.

Central India States.—Weather rather cloudy. No more cholera in Residency. Health good. Prospects favourable. Prices stationary.

Rajpootana.—Weather cloudy and stormy. Tanks and wells good. Prices rising in Marwar, but stationary elsewhere. Outturn of grain and opium crop average. Cholera in Tonk during week. Small-pox prevalent in some districts. Public health generally good.

Nepal (May 7th).—Weather seasonable and cool. Prospects fair.

Letters to the Editor.

REAPING PADDY BY MACHINERY.

TO THE EDITOR.

SIR,—Of all agricultural operations, harvesting paddy is the most tedious. And the loss from the sludding of grain and liability to showers which occasionally overtake it, is very great. It is impossible to realise the heavy loss from these misfortunes without actual experience. Several varieties of paddy which yield well, but shed the grains readily, cannot be cultivated on this account. Now, the question is, can you successfully introduce reaping machines on paddy fields? The fields must be large, at least 4 to 5 acres, if not larger. The wheels of the reapers should be broad, as the soil is generally wet in October and November. The machines should be of the simplest description, such as (field) mowing machines. Several attempts have been made to introduce reaping machines on indigo fields. I do not know how far they have proved successful. But as indigo is mostly grown at contract rates, and the cutting is generally managed by the ryots, and not by the indigo planters themselves, there has been no want felt for an indigo-cutting machine. From what I have seen of the management of machinery by tea garden coolies, I am not in the least afraid of the ryots not being intelligent enough to manage reaping machines. They will require a little teaching at first, as in everything else, and with that, they can be well left to themselves. Now, the question is, can reaping machines be introduced on Bengal paddy-fields? I write to you from a place that Dame Nature never meant for paddy cultivation. The land is steep, and the fields are necessarily very small. There are about 10 to 40 fields to an acre. It is on the plains, where the fields are large, or can be made large, that the introduction of reaping machines may be safely attempted; and it is only the zamindars who have cultivation of their own, and the well-to-do ryots who can afford to make any experiments.

S. DATTA.

Meherbhunj, April 23, 1885.

NOTE.—We are glad to receive this letter from our correspondent. The subject is an important one, and we hope the readers of the *Indian Agriculturist* will favour us with their views on the point raised in this letter.—Ed., I, A.

Editorial Notes.

We learn that the topographical survey of the Andaman Islands, which was commenced some two years ago by Captain Hobday, of the Survey Department, who had his head-quarters at Port Blair, and has also a vessel placed at his disposal for the purpose, is progressing satisfactorily.

We understand that the first meeting of the members of the Committee of the Bengal Branch of the Indian Court of the London Exhibition, recently appointed by the Local Government, was held on 15th instant, and that an officer in charge of the exhibits, and a few artisans in connection with certain classes of articles, will be sent to England by the Government of India.

A CONTEMPORARY learns that the Forest Conservators and the Board of Revenue at Madras have reported unfavourably on a suggestion that a School of Forestry should be opened in connection with the Agricultural College at Saidapet. It is considered that the present plan of sending students to the Forest School at Dehra Doon cannot be improved upon. It is further pointed out that in any case Saidapet would not be a suitable place for such a school, inasmuch as the place does not possess the forest surroundings requisite for practical instruction.

THE suggestion of the Government of India for the exemption of Railway Companies from the payment of land-cess, under section 37 of Act IV. of 1871, and section 63 of Act V. of 1884, has been adopted by the Madras Government, who have sanctioned the remission of all demands against Railway Companies on account of land-cess under Act IV of 1871, section 37. We have no information as to whether the suggestion has been adopted in the other presidencies and provinces; but the presumption is that it has.

Apropos of Mr. Doyle's contribution dealing with the Lucknow Paper Mill, some very curious statistics as to paper-making have recently been compiled on the Continent. It seems that there are 3,985 paper mills on the face of the earth, in which annually 1,904 million pounds of paper are manufactured. Half of this paper is used for printing; 600 million pounds only for newspapers, the consumption of which has risen by 200 million pounds during the last ten years. As to the use of paper by individuals, an average of 11½ lb. is used by an Englishman, 10½ lb. by an American, 8 lb. by a German, 7½ lb. by a Frenchman, 3½ lb. by an Italian or Austrian, 1½ lb. by a Spaniard, 1 lb. by a Russian, and 2 lb. by a Mexican. If the consumption of paper is a gauge of civilization, this table of averages is very flattering to our national conceits.

A CORRESPONDENT from Motihari, writing under date the 6th instant, furnishes the following items of local news:—After an extended drought of many weeks, we had at last two good showers of rain on Monday and Tuesday evenings. The rain on Monday was accompanied with hailstorm, which did considerable damage to the remnant of the scanty mango crop of this year. The rains, however, will do much good to public health and cultivation. The prospect of the indigo crops is now more hopeful. The price of rice has gone up considerably in comparison with pulses and grains. Cases of fever and chicken-pox are reported from the town and its suburbs.—The other day a sad occurrence took place in the lake fronting the Magistrate's bungalow. Two men, while crossing in a boat, were drowned by its upsetting at a short distance from shore.

On the 24th March, Captain Plummer, of the Mysore Gold Mining Company, reported to his Directors: "Mining Operations: We have a full party of men sinking Taylor's shaft under the 173. There are three shifts worked, mornings, afternoons, and nights. One Englishman and six coolies are employed in each shift, and as the cost of the Englishman is so great compared with the coolies, no bargain is let, the Europeans take full charge and responsibility, and the coolies are paid 6 annas per day. Very good work was done last week. We have got into proper trim for sinking on the lode, and we carry the western wall in the shaft.

The lode is 4½ feet wide; assay value 4 ozs. 9 dwts. 20 g.s. per ton. We have not been able to keep the bottom south and full-headed. The lode appears to be getting smaller, though it is now 4 feet wide; assay value this week 5 ozs. per ton. Three men only have been employed at the bottom north end. I have already informed you that the quartz is cut out. Our great aim is to get through to No. 1 winze."

A few months ago Messrs. Parry and Co. brought to the notice of Government that by the failure, during the floods of December last, of the Veranendy division bund, which takes off the overflow of the Pooniar near the Tirugalur anicut, a large volume of water was thrown into the Malabar stream, which consequently left its own bed, and in finding a new course damaged their property to the extent of Rs. 12,000, at the Tiruvannellore factory, and they urged the liability of Government for the damage. The matter being reported upon by the Public Works Department, the Government observed that after a careful perusal of the papers, it was unable to acknowledge that any obligation attached to the Government to protect the factory belonging to Messrs. Parry and Co. at Tiruvannellore, while it was of opinion that the proposal to abandon the ruined Koriar embankment and construct an embankment across the Malabar below the head of the Koriar channel was based on good ground, and that the embankment would prove an efficient protection to Messrs. Parry and Co's property. It was, however, beyond doubt that the factory buildings had been constructed on a site which was liable to damage on the occasion of such extraordinary floods as those of December last, and any risk that may consequently be incurred must be accepted by the owners of the property.

THERE seems to have been some misapprehension in regard to the representation of the Madras presidency at the London Exhibition of 1886. We find that the officer in charge of the Exhibition Branch of the Government of India, in the Revenue and Agricultural Department, addressed a letter to Mr. Wilson, the Director of Revenue Settlement and Agriculture, Madras, whose co-operation he solicited in obtaining a complete collection of silk moths, cocoons and raw silks for the Indian collection of exhibits to be sent to the London Exhibition. This letter he communicated to Major Walker, the Conservator of Forests, Southern Division, for such action as was necessary. Major Walker, however, has suggested that the Madras presidency should be separately and independently represented at the coming Exhibition in forest and agricultural produce, and that he is taking steps to get together a really good and representative collection of forest produce; but that he cannot undertake to make two collections—one for India, the other for Madras.

THE Government of Madras, in passing orders on this subject, have decided that they do not consider necessary that the Forest Department should act independently in the matter of forwarding exhibits; the Government of India, it is said, had already called for a set of wood specimens for the Exhibition, which had been forwarded. The collection of silk moths and raw silk now desired, is to be obtained by the Director of Settlement and Agriculture; and that any supplementary exhibits, which the Forest Department may desire to forward, should be sent through the Committee now working in Madras, to secure an adequate representation for that presidency on the occasion.

COLONEL H. T. ROGERS, Superintendent, Madras Survey, has submitted a proposition statement, together with certain additional information called for by the Madras Government, for the reorganization of the Survey Department. Colonel Rogers's revised proposals will involve an expenditure of Rs. 7,57,308 against Rs. 6,59,130 on the present scale. The period for which this expenditure is estimated will range from 1884-85 to 1888-89, or five years, and the forecast of anticipated outturn of work during this period for five parties is 8,345 square miles of topographical survey; but this includes Malabar, where very slow work is looked for. These proposals, with a few unimportant modifications, have been approved and sanctioned by the Madras Government.

It may be observed here that Colonel Scott, the former Superintendent, estimated these surveys for four parties, to

accomplish 12,000 square miles of revenue, 1,000 square miles of forest, and 3,000 square miles of topographical survey, at a cost of Rs. 5,70,000. The Madras Government think that the outturn for the five parties recommended by Colonel Rogers in ordinary districts, should be 9,650 square miles of revenue, and 13,985 square miles of topographical, or an average per annum of 1,930 and 2,797 square miles respectively, for eight lakhs of rupees. This is a very important work, and much valuable information is looked for from the labours of the five survey parties now proposed.

.

We learn that the report recently by Mr. Wilson, Director of Revenue Settlement and Agriculture, Madras Presidency, on the working of the Madras Cattle Disease Act II of 1886, in that Presidency, has been referred by the Madras Government to the Government of India for their information. The Act does not appear to have been very extensively worked; but its provisions were partially applied in 1876 to the Wynnad District, to check an outbreak of rinderpest; in 1879 to the Nilgiris, on an outbreak of rinderpest occurring amongst the Toda and Badaga cattle, and in 1882 to the Trichinopoly District. Mr. Wilson's conclusion, from such experience as has been gained, is that prompt and immediate segregation is the best way of checking the spread of disease, and that proper medical treatment will save a large proportion of the animals attacked.

.

A CONTEMPORARY publishes the following suggestive article:—

The East is popularly supposed to have been the home of the parable, and a talent for parable-making undoubtedly survives in certain secluded parts of this country. The Deputy Commissioner of the Sumbulpore District in the Central Provinces was met, when entering a village one morning, when the sun was high, by a torch-light procession. Being somewhat puzzled he inquired whether the superfluous illumination was in honour of some local deity unusually anxious for light, or whether it was only an outburst of local loyalty in his honour some ten hours before its time. He was gravely informed that the people of the village considered the torch-light necessary to guide him through the darkness which had overshadowed them under English rule. Of course he asked—as he was meant to ask—what tangible proof they had to give of this darkness that could be felt at midday. And it then transpired that a neighbouring village headman had cut and carried timber from forest-land which the torch-bearers regarded as peculiarly their own. The guileless villagers were wise in their generation. Their ingenuity and the outlay of an anna or two on oil saved them a 15-miles journey for the purpose of getting a petition written; the payment of writing fees (an amount which is too often well worth saving); and a further long journey to present the petition, to say nothing of the superiority in point of force of complaint by tableau over the everyday *urzi*.

.

The following is a summary of William James and Henry Thompson's fortnightly circular of Indian and Ceylon Teas:—Upwards of 38,000 packages have been catalogued for sale during the fortnight, including 2,600 packages of Ceylon and 4,100 packages of second-hand and reprinted tea. Demand has continued strong, and prices for all but the lowest grades have favoured sellers, quotations being especially firm for good Pekoes and Broken Pekoes and for the finer sorts of Pekoe Souchong and Broken leaf; while inferior kinds closed a little cheaper than last week, but with buyers at the reduction. Duty has been paid from the 1st to the 21st instant, upon 18,000,000 lb., as against 7,000,000 lb. last year—and the clearances from the warehouses continue heavy. During the past few weeks the dealers have been selling freely, and are now preparing for a period of quietness after the Budget. As the date of the Budget has been altered to 30th instant, auctions will be held on the 27th and 28th instant, 9,000 packages being already advertised; this week's sales ceased on the 21st instant. There remain about 55,000 packages to be sold to close the crop, against 100,000 packages at this date last season. The exports from Ceylon from the commencement of their shipping season (called 1st October) to 26th March were 1,000,000 lb., against 600,000 lb. in the previous year. About 6,000 packages have been sold here in the past two months, the average price being

1s. 3d., the same as was obtained last year for about half the quantity: many of the later imports show improved quality, and are readily taken by consumers.

.

The general conclusion to which the Conservator of Forests has come is, that although the information available from most districts is too vague to admit of definite conclusions being arrived at at this stage, he is convinced, after recent inspection of the mahogany trees at Nilambur, that this valuable timber tree can be grown to advantage in the Madras Presidency under suitable conditions as regards soil, climate, and congeners. The mistake hitherto made in Nilambur has been planting too close and with too much shade. In proposals, which he is now framing, for an extension of the Nilambur plantations, he advocates planting the mahogany in alluvial soil at 50 feet apart as standards along with teak to be treated as coppice, and feels confident that this method of treatment will result in success—an opinion in which Messrs. Morgan and Hadfield concur. The larvæ of the moth (*Pyralidæ*) is certainly a dangerous enemy, but he doubts if serious damage will be done by it to trees growing vigorously under suitable conditions, such as are apparent in the case of the isolated tree in the Chathambari block, which has never been attacked.

.

We have before us the official papers on the reconnaissance survey made nearly two years ago, of the country between Mogulserai and Daltongunge, which will form the first section of the proposed through line to connect Pooree with Benares. The Government of India showed considerable 'anxiety' for these surveys, but it remains to be seen whether any steps towards the construction of the line will be taken during the ensuing working season, now that survey parties have been for two seasons in the field. We learn that the country between Mogulserai and Daltongunge, which is to form the first section, has been thoroughly explored, and that the alignment follows in the first instance, the direction of the Grand Trunk-road, towards the large city of Sasseram. The line will then take a southerly direction, and run by the Sone river, until it passes beyond a point above the confluence of the Sone and Koel. At a place marked Scrinningger, opposite to Percha, the line crosses the Sone, and following a southerly and easterly direction goes on to Gaddie, some five miles north of Daltongunge, where we believe an extension of the Patna-Gya line is intended to join it. It appears that the difficulties which presented themselves, have been completely met by (1) running the line in the direction of the Grand Trunk-road, thus skirting along and round the range of hills lying to the south of Mogulserai, and (2) by crossing the Sone at a narrow point, with a good foundation. The great difficulty, however, was the spanning of the Sone river, but that also is removed now that borings have been taken, and it is found at how small a depth the foundations for a bridge will find a rocky base. The decision to run the line by Sasseram is in the right direction.

.

In the *Statesman* of the 12th March last, the "Coal Question" was ably discussed by a correspondent X, who was evidently well qualified to deal with it. The frigid indifference of the Government to the Rewa coal-fields was animadverted on, as shewing an apparent intention to exclude the Rewa product from the market. We are glad, however, to find that our correspondent's notions in the matter were mistaken, and that the best steam coal in India—which Mr. Hughes, of the Geological Survey, has proved to exist in the Native State of Rewa—will no longer remain undisturbed, and that the Railway Companies of Central and Western India will get access to what ought to be their cheapest fuel supply. A satisfactory beginning has been made in regard to the working of these coal deposits—said to be the richest yet discovered in the East. Shafts have been sunk and coal mining commenced by Mr. Thomas Forster, the well-known mining engineer, to whom we referred in these columns in connection with the catastrophe at Warora, in 1882, when Mr. Forster recovered the under-ground workings, and restored the Government colliery there, into working order. Mr. Forster has since been associated with Mr.

HUGHES, his chief, in the examination of the Rewa-Gondwana basin, and the first fruits of his practical exertions in seconding Mr. HUGHES's efforts, towards the establishing of an extensive colliery at Umaria, is the news to hand, that several thousand tons of coal are now awaiting the opening of the railway from Kutai, which will connect the mines with the East Indian Railway. When we consider that the prospect of the field is an annual out-put of 300,000 tons, the importance of the undertaking to the Native State concerned, cannot be over-estimated. Its enormous value, geographically and economically, to the British Indian Railway system, needs no comment.

**

Mr. C. S. CROLE, Collector of Madura, has been brought to book by the Madras Board of Revenue in reference to his recommendations for dry remissions in certain taluka, which he alleges have suffered severely from drought, floods and other causes. Thus Mr. Crole says generally that the ryots, presumably of the whole district, reaped little or no harvest from their early dry crops, while their subsequent cultivation was affected by the heavy rains and floods—the outturn of the crops then standing being estimated at from four to eight annas in the bad tracts, and from two to four annas in the worst. He gave no statement of villages affected, or of estimated remissions in each village, but made an indefinite recommendation to grant a remission of from 25 to 50 per cent of the whole assessments of all the dry lands in some taluka (not specified). Further on in his report, he did not consider that any remission for dry waste was called for; but whether this opinion was intended to apply to the whole district, or only to some, was not clear. If intended to be of general application, the Board were of opinion that recommendations for dry remission, which advisedly excluded from their scope dry waste, carried condemnation on their face. Mr. Crole then recommended that 25 per cent of the whole "dry" assessment of the district (which amounts to nine lakhs of rupees) be remitted in those tracts which he considered "bad," and 50 per cent of those classified as "worst." This the Board declined to sanction.

**

Mr. CROLE, however, asked for a reconsideration of the Board's order, on the ground that their assumption that the year 1883-84 was not a bad year was erroneous, and the floods in the Voigai in that year were of so terrible and unprecedented a character as to necessitate "dry" remissions everywhere. The Board, however, failed to see the force of Mr. Crole's contention, and were of opinion that he had gone out of his way to recommend dry remission throughout the district, when they were not required, but they would not object to sanction full remission for dry crops actually washed away by floods. Beyond this they were not prepared to go. The Board added that they were constrained to notice the persistent tendency of Mr. Crole to recommend remissions without due reason, and to submit his proposals in an incomplete shape.

**

THE Government of Madras thought that the state of the Madura district, brought to notice in the papers before them, called for some measure of relief in respect to dry lands. They considered that one-fourth remission should be granted on land ordinarily cultivated, but left waste in the season under reference, as also on land cultivated before 1st October in certain taluka. The indulgence in the case of cultivated land was to be restricted to areas unprotected by wells. The conclusions we draw from these discussions are, that Mr. Crole, although his recommendations were based on good ground, had not taken sufficient pains to submit them in proper form in the matter of detail; while the Board were unduly hard upon him, we think. The Government, however, took the middle—and consequently the safe—course, thereby satisfying both parties.

**

We have before us the details of the forecast of the wheat crop in the N.-W. Provinces and Oudh for the month of March 1885. The agency employed was, as before, the Putwari and Kanungo establishments. The method also was the same. Doubtful areas were revised and wrong areas rectified after

inspection in the field. The area under pure wheat returned for February was 52,66,319 acres. The area as now ascertained is 52,84,404 acres, or an excess of 18,085 acres over February. This excess is accounted for by the greater accuracy attained in distinguishing fields of pure wheat from those under wheat mixed with barley. A considerable area of land which was really under pure wheat had been wrongly regarded as under wheat *cum* barley. This error was corrected in the March inspections. Hence the excess in area.

**

TAKING the normal area under pure wheat (49,65,688) at 100, the area as now ascertained is represented by 106. The new feature in the present report is a statement which gives the areas under white, red, and mixed wheat separately. According to the February forecast, these areas were under white wheat 12,11,762 acres; under red wheat, 20,02,643 acres; under mixed wheat, 20,50,914 acres; total, 52,66,319 acres. In the same order we have for March 1885, 12,13,980; 20,10,239; 20,60,185 respectively; total 52,84,404, or as stated before, an increase of 18,085 acres. The difference, however, is not much.

**

MR. D. SMEATON, the Officiating Director, says that his information regarding the condition of the crop was derived almost entirely from non-official sources. 402 selected zemindars and talukdars had been invited to send in returns; and that out of the 402 gentlemen, 360 had sent in returns for March, which reached him punctually, and bore traces of care in preparation.

The weather was seasonable throughout the year. Taking 100 to denote a crop in full average condition, the outcome of the reports sent in by the selected zemindars is as follows:

52,624 acres stand	ft	100
6,41,323	"	"	"	90
28,03,881	"	"	"	84
17,40,481	"	"	"	75
42,455	"	"	"	66

**

THE districts had been classified into four tracts, viz.—(1) The Meerut Division, (2) Sub-Himalayan Tract, (3) Central and Lower Doab, and (4) Trans-Jumna tract. The standards of outturn adopted for a full average crop in each of these tracts is as follows:—

	Irrigated land.	Dry land.
	Mds. per acre.	Mds. per acre.
I. Meerut ...	18	12
II. Sub-Himalayan ...	15	10
III. Central and Lower Doab ...	14	7
IV. Trans-Jumna ...	10	4

But a very small area comes up to full average condition. The following estimate of gross outturn has been arrived at in the area as now ascertained:—

	Area under pure wheat.	Estimated full average.	Estimated harvest according to March harvest prospects.
Meerut ...	12,55,015	6,70,955	5,71,211
Sub-Himalayan ...	25,13,762	11,47,762	9,22,440
Central & Lower Doab ...	13,82,755	6,51,877	5,26,016
Trans-Jumna ...	1,32,872	25,766	21,862
Total ...	52,84,404	24,96,350	20,41,529

The full average crop of the United Provinces may therefore be put down at 2,500,000 tons. Of the outturn estimated for March 1885, the following are the proportions of white, red, and mixed wheats:—

White wheat ...	4,91,884 tons.
Red ...	7,45,185 ..
Mixed ...	8,04,460 ..

**

WITH regard to the question of obtaining correct information of existing stocks of wheat in the country, Mr. Smeaton has adopted three methods of obtaining estimates, viz.—(1) by taking an actual census of existing stocks; (2) by obtaining an estimate from the principal wheat traders, and (3) by estimat-

ing the harvests of three or four years back, striking yearly balances of stocks after deducting food consumption, seed, and exports. Thus he found that the wheat harvest of 1881-82 was a poor one. The gross production was not more than sufficient for the food and seed of the people, and for a very limited export during the year 1882-83. That the supplies were scanty is established by the fact that notwithstanding the very limited railway exports (42,28,520 maunds), the price of wheat during 1882-83 was considerably higher than in the previous year (1881-82) when the net railway exports amounted to 52,31,748 maunds, and slightly higher than the succeeding year (1883-84) when the railway exports amounted to 77,36,389 maunds. It may therefore be assumed that when the harvest of 1882-83 came into the market, the stocks of 1881-82 wheat were exhausted.

**

The crop of 1882-83 was good. According to the estimates of district officers it was a full average one—quoted all over the provinces at from 14 annas to 16 annas. We know the area cropped in 1882-83. Adopting, then, the standards of outturn given above, making the necessary deductions for food, for seed, and for export, it is found that in April 1884 the stocks in hand amounted to 6½ million of maunds, thus:—

Gross outturn of crop of 1882-83	...	62½ millions of mds.
Deduct food consumption 39½ millions of mds.		
" seed 7½	" "	
" total export 8½	" "	56½
Leaving stocks in hand in April 1884 at	...	6½ millions of mds.

Thus then when, in April 1884, the harvest of 1883-4 came into the market, there were stocks in the country amounting to 6½ millions of maunds.

The crop of 1883-4 was much below average:—

Gross outturn of crops of 1883-84	...	48½ millions of mds.
Add existing stocks of 1882-83 crop	...	6½ " "
Total	...	55½ " "
Deduct food consumption 39½ millions of mds.		
" seed 9½	" "	
" total exports 4½	" "	53½
Leaving stocks in hand in April 1885 at	...	1½ million of mds.

Computed in this way then the stocks of pure wheat in the United Provinces on the 1st April 1885 amounted to 1½ million of maunds, or about 64,000 tons.

In order to put this result to the test of facts, the Syndicate of Cawnpore grain merchants were invited to give an estimate of the total wheat stocks in the Provinces. They estimated the total stocks at about 10 lakhs of maunds or nearly 36,000 tons. These gentlemen have agents and correspondents at most of the chief grain marts in the Provinces, and are well qualified to give an opinion in regard to stocks in the hands of the big dealers. But there are considerable supplies stored in outlying villages waiting for a demand to spring up, and of these account must be taken.

In addition to the opinion of the Cawnpore syndicate, enquiries were made in regard to stocks in the following places:—

Meerut district,
Mousharugger town,
Aligarh town,
Bathra tehsil,
Moradabad town,
Shahjehanpore town,
Hardoi tehsil:

and it was found that in these, there are at the present moment stocks amounting to 12,000 tons. Looking to the result of the computation given above, to the opinion of the Cawnpore syndicate, and to the results of the partial census just given, it may safely be said that the stocks of wheat in the United Provinces on the 1st of April 1885, immediately before the harvesting of the 1884-85 crop, amounted to not less than 60,000 tons. This estimate, if correct, should serve as a basis for all future estimate of stocks of wheat in the provinces.

* In towns at 2½ maunds per head; in country villages at 30 acres per head.

† At 1½ maunds per acre.
‡ At 1½ maunds per acre.

The cultivation of the mahogany tree (*Swietenia mahagoni*) in the Madras Presidency has been attended with more or less of success, the chief difficulty being found in the delicacy of the seeds, or rather their germinating qualities. We find from the report of the conservator of forests, Southern Division, that the first batch of seeds were received in January 1872 from British Honduras; but their vitality had been quite destroyed. This was ascribed to the manner of packing, viz., in their capsules. The next batch of seeds were received packed in two different ways. The method recommended by Major Beddome was that they should be taken out of the capsules, dried in the sun, and packed in perfectly dry sawdust or charcoal; the other method being to have them in their capsules. It was found on trial that the seeds packed according to Major Beddome's method germinated best; but the success obtained even from this batch was but of a negative kind. The experiment tried with a further batch five years later, also resulted in marked failure, until September 1879, when a lot of seeds received from Jamaica were sown at Nilambur, out of which some 12,000 germinated. From this stage the experiment at Nilambur may be said to have been established.

**

The directions for sowing mahogany seed, issued by the Superintendent of the Royal Botanical Gardens, Calcutta, are as follows, and may be observed as a general rule:—Put the seeds into the soil, so that the broad thick end of each seed shall be lowermost, and let only this part be covered. Leave the thin end sticking out of, and uncovered by soil, keep in a shady place under cover, and water gently. Transplant the seedlings into pots when they are about three or four inches high. Transplant into the situations which they are permanently to occupy, when the seedlings are from fifteen to eighteen inches high.

**

At Nilambur there are at present about 3,000 plants surviving, of those raised from seed received from Jamaica in 1879, including one tree which has survived from the batch of seed received in 1872. This tree is 11 years old, 67 feet high, and measures 3 feet in girth from 5 feet from the ground. It is a healthy specimen, growing in rich alluvial soil, surrounded by teak trees. Besides the Nilambur plants, experiments have been tried with varying success at Coimbatore, Tinnevely, Madura, Tanjore, South Arcot, and Chingleput.

**

The method of cultivation recommended by Mr. Morgan is as follows:—

"The plantation should be pitted in May 6' x 6' apart, or 1,200 pits to the acre. In every tenth pit each way, which should be 2½ feet cube, the mahogany should be planted and timber trees of the same rate of growth, should be put down as nurses in the other pits. If these latter are not of similar growth, the mahogany is either outstripped and deprived of strength, or it throws out lateral branches too early.

The nurseries for the mahogany and the other trees should be made at the same time, the soil being rich and mixed with leaf mould and river sand, and the beds should be raised from four to six inches to let water run off. The seed should be sown without delay in the manner indicated by the Superintendent, Royal Botanical Gardens, Calcutta, the soil being shaded for the first four days or so with fine grass. The radicle generally protrudes about the fifth or sixth day. After germination, various moths destroy the seedlings, and they must be searched for just below the surface in the mornings and destroyed daily. When the plants are five inches high, they should be potted in rich soil in large bamboo joints to admit of proper drainage, care being taken that the tap roots are not twisted or turned up.

In June, when the south-west monsoon bursts, the plants should be planted in these pits in the larger pits, care being taken that the tap root does not get injured. When the pot has been placed in position, the rich surface soil alone should be raked into the pits.

The plants should be staked to prevent their getting "wind wrong," their stems being protected with rag or grass where tied to the stake. The nurse seedlings can then be planted.

The plantation should be regularly weeded, failures being planted up, and any nurses threatening to dominate may be cut back to the height of the mahogany near them.

There should be periodical thinnings, and after the final one, the nurseries may be felled out.

Mr. J. F. DUTHIE, F.L.S., Superintendent of the Government Botanical Gardens at Saharanpore, recently transmitted to Sir J. Hooker, Director of the Royal Gardens, Kew, a specimen of spider silk obtained by him in Kumaon. Mr. Thos. Wardle, of Leek, a well-known authority on Indian fibres and silks, who was consulted regarding the samples, furnishes the following report:—

"Sir George Birdwood has written to me, enclosing some spiders' web and an extract from Mr. J. F. Duthie's letter. He asks me to examine this spider silk and to reply directly to you. The following is the result of my examination:—The fibre is evidently of a silken nature, and, like silk, it is loaded with a gummy substance. In a boiling soap solution this gum or varnish dissolves, leaving the fibre apparently pure and of the nature of fibroin, if not identical with it. Eight micrometric measurements of the diameter of the fibre in different parts of the mass showed great irregularity in thickness (1/2300', 1/2800', 1/3500', 1/2900', 1/3500', 1/3500', 1/3500', 1/3500'), giving an average of 1/3100 inch. It has therefore a considerably finer thread or fibre than silk, Italian silk averaging in thickness 1/2100 inch. The average strength of the spider silk proportionately is greater than that of silk, a single fibre of the spider silk breaking with an average weight of 2½ drams avoirdupois, whilst that of China silk breaks at 2½ drams. The most curious property of this fibre is its elasticity, which is considerably greater than that of silk; 30 centimetres of it will stretch to an average length of 33·3 centimetres before breaking, whilst China silk will only stretch to 34 centimetres. Like silk, this spider's web silk is lustrous and has a round fibre. Its coating of gum or varnish is disproportionate to the weight of the silk. On boiling with soap it lost 7½ oz. per lb.—that is, 1 lb. of the spider silk discharges 7½ oz. of gum. With silk the proportion is much less, seldom being over 25 to 30 per cent. Before boiling in soap the spider silk was well combed to remove all the dirt possible, but a little remained. The fibre appears to dye readily. I enclose a small pattern of it dyed, and also one as I received it, and one after boiling in soap. I believe if it can be obtained in quantity, it might be packed in bales and sent to England, where it would readily find a market for being carded and spun into silk thread for sewing or weaving purposes. It is difficult to estimate its marketable value. I dare say it would at any rate realize 2s. per lb. It is rather dirty, and this would to some extent detract from its value as compared with silk waste. I have tried to discover how many seripositors this spider has, but beyond noticing under the microscope that the fibres often run in pairs, but not regularly, I am unable to trace whether there are two, as in the ordinary silkworm, or more. Probably an examination of the spider would show this, or an undisturbed portion of its secreted silk."

Mr. Duthie believes that, if a large supply of the spider silk were wanted, it could easily be obtained near the lake at Bhim Tal in Kumaon after the rainy season is over.

SUGAR CULTIVATION IN INDIA.

THE Government of India in the Revenue and Agricultural Department have very courteously placed at our disposal a mass of correspondence containing statistics of sugar cultivation in India, and other valuable information bearing on the subject. The sugar industry is attracting a very large share of attention at the present time, both at home and abroad; and as the importance of the subject is generally admitted on all sides, it will be interesting, we believe, to give the public as accurate an estimate as possible of the state of this industry in India, and the dimensions it has assumed during recent years. The Government of India, who called for statistics from the several Local Governments and Administrations, and the territories subordinate to them, would be in a better position to form a correct estimate of the extent of sugar cultivation in India than any other independent authority, and we shall, therefore, here review the official papers placed before us, to do which we shall go back a few years.

In March, 1879, the Secretary of State for India called for a corrected and complete statement regarding the then present state of sugar cultivation, whereupon the Government of India called upon all the Local Governments and Administrations for the

information required; which, when received, gave the area under sugarcane at 1,922,263 acres. In addition to this, there were 168,262 acres under the date palm, 14,100 acres under the palmyra palm, and 2,930 under the cocoa palm, all of which yield sugar; thus giving a total area under sugar of 2,107,575 acres. This information was sent to the Secretary of State in May, 1882. The circumstance that induced the Home Government to call for this information was the fact of the *Produce Markets' Review* having published certain statistics in this connection, which appeared to require some explanation. It was found that, excluding Bengal, and omitting the area under the date-palm and other sugar-yielding trees, the Indian returns gave 1,737,925 acres of sugarcane in British India, against 1,603,383 acres shown in the *Review*; and that the conjectural estimate for Bengal of 1,400,000 acres put forward by that journal, was seven times in excess of the actual area, viz., 184,259 acres, at which the Government of Bengal returned the area under sugarcane. Bengal, although having an area double that of the North-Western Provinces, has a very small area proportionately under sugarcane cultivation. Thus the vast province of Orissa had less than 4,000 acres, the reason for this being that a large portion of the province is unfitted for the production of sugarcane, being better fitted for the cultivation of rice, jute, and other valuable staples. Nearly half the entire area of 184,259 acres given for Bengal appertained to the Patna division, which adjoins, and resembles in climate and other conditions, the N.-W. Provinces, which is favourable to the cultivation of the cane.

No accurate statistics, however, were then available for the Native States of India; but from the information received up to 1882, it was inferred that very little sugarcane was grown in those territories. The Rajpootana and Central India States were known to draw their supplies of sugar from the N.-W. Provinces and the Punjab. In some parts of the Hyderabad State, however, the sugarcane was one of the staple crops; but the produce was considered to be probably not more than enough for the requirements of the population. In Mysore, for which the last returns furnished by the Chief Commissioner were those for 1878-79, the area under sugarcane was shown at 12,691 acres, and that under the date-palm at 29,093 acres.

In a despatch to the Secretary of State dated the 16th May 1882, the Government of India observed that the acreage returns for British India may be taken as approximately correct, with the exception of those for Bengal. It was added that the absence of agricultural statistics of a reliable character for this province had been frequently brought to the notice of the Home Government, and was prominently noticed in the report of the Famine Commission. This was a serious charge against the Bengal Presidency, and more than justifies the recent comments made in the public newspapers regarding the unsatisfactory manner in which agricultural statistics were generally obtained by this, the parent Presidency of British India. The Government of India clearly recognised the defective administration of Bengal in this most important respect, and the fact having been recognised, it has always been a matter of surprise to us why it should so long have been excluded from the list of Presidencies under which Agricultural Departments had been established in accordance with the recommendations of the Famine Commission. We have been led into making a digression here from the subject-matter of this article; but the pertinency of our remarks will be apparent from the following remarkable statement made by the Government of India, when submitting to the Secretary of State the statistical information on the cultivation of the sugarcane. Referring to Bengal, the Government of India said: "It is, however, very probable that the sugar-cultivation of Bengal is understated in the present returns. The estimate made by the Famine Commissioners on the best available evidence, was over one million acres; and though the date on which this estimate was framed are not given, the Commissioners had exceptional opportunities for arriving at a correct conclusion." The italics are ours. When we compare the estimated total area for Bengal as furnished by that Government, viz., 184,259 acres, with the estimate of the Famine Commissioners (who "had exceptional opportunities for arriving at a correct conclusion") who put it down as being "over one million acres," which is 815,742 acres under

the mark! we cannot help being somewhat staggered at this extreme disparity between the two figures. We shall abstain from making any further remarks on this point. The two figures are, to use a paradoxical expression, silently-eloquent, and speak for themselves; we shall therefore proceed to take up the next point, viz., the outturn per acre.
